## CALVARY.

CALVARY, or Golgotha, in *Ancient Geography*, a mountain of Paleſtine, held in the greateſt veneration as the ſcene of our Saviour's crucifixion. It acquired theſe two names, probably, from its roundneſs, or reſemblance to a human ſkull, or, as others ſay, from its being bare and deſtitute of verdure. Theophylact ſays, that by a tradition deſcended from the fathers, Adam, (or as others ſay, Adam's head) was buried here, and therefore, ſays he, Chriſt, who was to heal the fall and death of Adam, was here crucified, that where the beginning of death was, there might be the diſſolution of it. The witneſſes of this tradition adduced by Theophylact are Origen, Tertullian, Epiphanius, Athanaſius, and St. Auguſtin. St. Jerom obſerves, that this is a favourable interpretation, and pleaſing to the ears of the people; but not true. It anciently ſtood without the walls of the city of Jeruſalem, and was the place where criminals were executed according to the Moſaic law. But the Roman emperor Adrian having ordered the city to be re-built a little to the north of its former ſituation, Mount Calvary was encloſed within the walls. See Ælia *Capitolina*. This mountain was cleared by order of Helena, the mother of Conſtantine; and fitted for the foundation of a church by cutting down ſeveral parts of the rock and elevating others. But this was done with ſo much care, that no part of the hill which immediately related to our Saviour's paſſion was altered or diminiſhed. Accordingly that part of Calvary, where it is ſaid Chriſt was faſtened to the croſs, is left entire; being about 10 or 12 yards ſquare. The magnificent church erected on this ſpot by order of Helena was, therefore, built in ſuch a manner as to comprehend as many ſcenes of our Saviour's ſufferings as could be conveniently encloſed. This ſtately edifice is ſtill ſtanding, and kept in good repair, by the offerings of the pilgrims, who annually reſort to it, as well as the contribution of ſeveral Chriſtian princes. It is 100 paces long, and 60 wide; the walls of it are of ſtone, the roof of cedar; the eaſt end encloſes mount Calvary, and the weſt comprehends the holy ſepulchre. The former is covered with a noble cupola, ſupported by 16 maſſive columns, which were encruſted with marble. The centre of it is open on the top juſt over the ſepulchre; and above the high altar at the eaſt end is another ſtately dome. The nave of the church conſtitutes the choir, and in the inſide aiſles are the places where the moſt remarkable circumſtances of Chriſt's paſſion were tranſacted, together with the tombs of Godfrey and Baldwin, the two firſt Chriſtian kings of Jeruſalem. An aſcent of 22 ſteps leads to a chapel, where that part of Calvary is ſhewn on which Chriſt was crucified, and the very hole in the rock, in which his croſs was fixed. The altar hath three croſſes in it, and is richly adorned with other coſtly embelliſhments, particularly with 46 ſilver lamps of immenſe value, that hang before it and are kept conſtantly burning. Adjoining to this is another ſmall chapel, fronting the body of the church. At the weſt end is that of the ſepulchre, which is hewn out of the ſolid rock, and has a ſmall dome or lantern, ſupported by pillars of porphyry. The cloiſter round the ſepulchre is divided into ſundry chapels, appropriated to the ſeveral ſects of Chriſtians, who uſed to reſide there, ſuch as the Latins, Greeks, Syrians, Armenians, Abyſſines, Georgians, Neſtorians, Cophtites, Maronites, &c. But theſe, ſays Maundrell, except four, viz. the Latins, Greeks, Armenians, and Cophtites, have abandoned their quarters, not being able to ſuſtain the ſevere rents and extortions, which their Turkiſh landlords impoſe upon them. The apartments of the Latins are on the north-weſt; to them belongs the care of the church, and

Strahan and Preſton,
New-ſtreet Square.

they make every day a ſolemn proceſſion, with tapers and crucifixes, and other ceremonies, to the ſeveral ſanctuaries of the church. Accordingly they are obliged to reſide conſtantly in it; the Turks keeping the keys, and not ſuffering any of them to go out, but obliging them to receive their proviſions through a wicket. Eaſter is the time at which the chief ceremonies are performed within this place; and theſe chiefly conſiſt in repreſentations of Chriſt's paſſion, crucifixion, death, and reſurrection. At this ſolemnity, every pilgrim, paying a certain fee, is admitted to aſſiſt at the ſolemn proceſſion and other ceremonies: of theſe there is commonly a vaſt concourſe. Some of them chooſe to enter on Good-Friday, and ſtay till Eaſter-Monday.

CALVARY, a term uſed in catholic countries for a kind of chapel of devotion, raiſed on a hillock near a city; in memory of the place where Jeſus Chriſt was crucified near Jeruſalem. Such is the Calvary of St. Valerian, near Paris; which is accompanied with ſeveral little chapels, in each whereof is repreſented in ſculpture one of the myſteries of the paſſion.

CALVARY, in *Heraldry*, a croſs ſo called, becauſe it reſembles that on which our Saviour ſuffered: it is always ſet upon ſteps.

CALUBO ISLANDS, in *Geography*, lie to the S.E. of Borneo iſland in the Eaſt Indies; a little to the S. of E. from cape Salatan, and to the W. of S. from Laut iſland.

CALUCULA, in *Ancient Geography*, a ſmall town of Spain, placed by Pliny and Ptolemy in the department of Hiſpalis.

CALVELUZZO, in *Geography*, a town of Naples, in the province of Baſilicata; 10 miles S. of Potenza.

CALVENSANO, a town of Italy, in the duchy of Milan, ſeated on the Adda.

CALVENTURAS, a ſmall iſland in the bay of Bengal, near the coaſt of Ava. N. lat. 16° 54′. E. long. 95° 20′.

CALVERT, GEORGE, in *Biography*, baron of Baltimore, founder of the province of Maryland in North America, was the deſcendant of a noble family in Flanders, and born at Kipling in Yorkſhire in 1582. After finiſhing his education at Oxford he became ſecretary to ſir Robert Cecil, in the reign of James I. by whoſe favour he was made clerk of the privy-council, and received the honour of knighthood. In 1619 he was appointed one of the principal ſecretaries of ſtate; but though he diſcharged the office with great fidelity and diligence, he reſigned it in 1624, honeſtly confeſſing to the king that he was become a convert to the Roman Catholic religion. He was continued, however, a member of the privy-council during this reign, and in 1625 created baron of Baltimore in the kingdom of Ireland, at which time he repreſented the univerſity of Oxford in parliament. Having been conſtituted by patent, during his ſecretaryſhip, proprietor of a province in Newfoundland, he named it "Avalon;" and expended upon it a large ſum. But though he twice viſited it in perſon, and reſcued it from a French invaſion, he at length abandoned it, and obtained from Charles I. a patent for the full property of the diſtrict ſince called Maryland. This he ſettled, and in his dealings with the natives diſplayed as much juſtice and good faith as William Penn did in his ſettlement of Pennſylvania. He likewiſe eſtabliſhed a moſt liberal code of religious toleration in his province, ſo that it became not only the reſort of a number of Roman Catholic gentlemen, who firſt accompanied the founder, but alſo an aſylum for many quakers and others, who were perſecuted by the bigotry of the puritans in New England. Lord Baltimore, who appears in all reſpects to have been a man *of worth* and ſound underſtanding, died at London in 1632. Biog. Brit. See MARYLAND.

CALVERT, in *Geography*, a county of Maryland, in the United States of America, on the weſtern ſhore of the Cheſapeak; about 33 miles long, and narrow.

CALVERT'*s Iſland*, an iſland in the North Pacific ocean, near the weſt coaſt of North America. N. lat. 50° 40′. W. long. 128° 10′.

CALVI, a town of Naples, in the province of Lavora, the ſee of a biſhop, ſuffragan of Capua; 5 miles N. of Capua, and not far from the ſea. N. 41° 15′. E. long. 14° 45′.

CALVI, a town on the weſt ſide of the iſland of Corſica, the principal place of a diſtrict in the French department of Golo, containing 2135 inhabitants. It is ſituated on a promontory which advances into the ſea, and forms one of the moſt beautiful harbours in the iſland, called "the gulf of Calvi." It is defended by a citadel on a rock with 5 baſtions; diſtant about 11 leagues W.S.W. of Baſtia. N. lat. 42° 26′. E. long. 9° 7′.

CALVIELLO, a town of Naples, in the province of Baſilicata; 12 miles S.S.E. of Potenza.

CALVIN, JOHN, in *Biography*, an eminent reformer, entitled on account of his talents and character, as well as his peculiar activity and zeal, to the ſecond rank of celebrity among thoſe who contributed to reſcue the Chriſtian church from the errors and ſuperſtitions of Popery, was born of an obſcure family, named Cauvin, at Noyon, in Picardy, in 1509. As he was originally deſigned for the church, he obtained at an early age a benefice in the cathedral church of his native place, and alſo the cure of Pont-l' Evêque. Having purſued the ſtudy of polite literature for ſome time at Paris, where he diſtinguiſhed himſelf by his proficiency, and where he alſo acquired a predilection in favour of the new opinions in religion, from a ſtudy of the Scriptures, recommended to him by Robert Olivetan, he determined to change his profeſſional deſtination; and applied to the ſtudy of the civil law, firſt at Orleans, and afterwards at Bourges. The Scriptures were likewiſe the objects of his particular attention; the more he acquainted himſelf with theſe pureſt ſources of theological knowledge, the more was he confirmed in the opinions he had adopted; and his attachment to them was ſtrengthened by intercourſe with Melchior Wolmar, a German profeſſor of the Greek language at Bourges. Upon his father's death he was obliged to return to Noyon, where he reſigned his eccleſiaſtical benefices; and ſoon after removing to Paris, he publiſhed, in 1532, an eloquent Latin commentary on Seneca's treatiſe "De Clementia," on clemency. In the title of this book he latinized his name Cauvin into Calvinus, whence he afterwards aſſumed his common appellation of Calvin. His attachment to the reformation being now generally known, he was under a neceſſity of ſuddenly quitting Paris, and of retiring to Angouleme, where he obtained a ſubſiſtence by teaching Greek. Here he was admitted into the houſe of Lewis du Tillet, canon of the church, whom he had proſelyted to the reformed religion; and during his reſidence in this place he wrote the greateſt part of his "Inſtitute." Notwithſtanding ſome degree of protection which was afforded him by the queen of Navarre, he thought it moſt prudent to leave France, and in 1534 he withdrew to Baſil, and in the following year publiſhed his celebrated work, entitled "Inſtitutes of the Chriſtian Religion." The deſign of this work was to exhibit a juſt view of the principles of the reformed, and to prevent their being confounded with the Anabaptiſts and other enthuſiaſts. It was addreſſed to Francis I. by a dedicatory epiſtle, which is much applauded as the fineſt ſpecimen of modern Latinity, and which was intended to ſoften the unrelenting fury of that prince againſt the Proteſtants. This work has been always much admired by perſons of ſimilar ſentiments, for the elegance of its ſtyle, the perſpicuity of its method, and the force of its reaſoning. It paſſed through ſeveral editions, which were ſucceſſively enlarged and improved; it was tranſlated by Calvin into French; and verſions of it were made in all the principal modern languages. To ſome editions is prefixed the device of a flaming ſword, with the motto, "Non veni mittere pacem ſed gladium;" *i. e.* "I came not to ſend peace but a ſword." After the publication of this work, Calvin went to Italy for the purpoſe of viſiting the ducheſs of Ferrara, who was a convert to the reformed religion, and who received him with great kindneſs. On his return to France, he propoſed to purſue his journey to Straſburgh or Baſil; but being obliged, on account of the war that then prevailed, to paſs through the territories of the duchy of Savoy, he took Geneva in his way; and being urged by the preſſing ſolicitation of Farel, Viret, and other zealous reformers, to ſettle in that city, he accepted the offices of preacher and profeſſor of divinity, which were conferred upon him with the conſent of the people, by the conſiſtory and magiſtrates. This ſettlement took place in 1536. In the following year he began to diſplay his arbitrary ſpirit, by obliging all the people to ſwear ſolemnly to a body of doctrines, which alſo contained a renunciation of popery; and by refuſing to celebrate the Lord's ſupper, till certain irregularities that ſubſiſted in the church at Geneva were rectified. He alſo declared, that he could not ſubmit to the regulations, which had been lately made by the Synod of the canton of Berne, and which required the uſe of unleavened bread in the euchariſt, the baptiſmal fonts which had been removed out of the churches, and the feaſts, which had been aboliſhed, to be reſtored at Geneva. This occaſioned a conflict, which terminated in an order of the aſſembly of the people, ſummoned by the ſyndics, that Calvin, Farel, and another miniſter, ſhould leave the city within two days. Calvin retired to Straſburgh, where he was allowed to found a church according to his own model. There he married a wife; and publiſhed his "Commentary upon the Epiſtle to the Romans." During his abſence, his friends at Geneva were very anxious for his return; and they at length prevailed, ſo that he arrived thither in September, 1541. After his re-ſettlement he began with eſtabliſhing a form of eccleſiaſtical diſcipline, and a conſiſtorial juriſdiction, inveſted with full powers to inflict all kinds of cenſures and canonical puniſhments, as far as excommunication. See Calvinism. This eſtabliſhment was much diſapproved by ſeveral perſons, who expreſſed their apprehenſions, that papal tyranny would ſoon be revived. Calvin, however, was inflexible; and on all occaſions aſſerted the rights of the conſiſtory, of which he was perpetual preſident, as he alſo was of the aſſembly of the clergy. But fully appriſed of the exorbitant power which accrued from this office, he adviſed, on his death-bed, that no perſon ſhould again be inveſted with ſuch authority; and after his time the office of preſident ceaſed to be perpetual.

Such was the extent of Calvin's ambition and views, that he formed a project of making the republic of Geneva the mother and ſeminary of all the reformed churches, as Wittemburg was of the Lutheran. From hence miniſters were to be deputed to diffuſe and ſupport the proteſtant cauſe throughout the world. Here he deſigned to originate an uniform model of doctrine and diſcipline; and Geneva was to be, as it were, the "Rome" of proteſtantiſm. His plan was purſued with vigour and perſeverance. An academy was inſtituted in this city, to which his own talents and learning, and thoſe of his colleague Beza, and of other eminent perſons, attached a degree of reputation that attracted ſtudents from all countries where the reformation had taken root. The ſucceſs of Calvin in his project was ſo great, that the preſbyterian model of church government gradually held a kind of divided empire with the Lutheran and Proteſtant epiſcopalian. When Calvin had formed and eſtabliſhed his ſyſtem of doctrine and church government, (See Calvinism,) he was too tenacious of his own opinion, and too arbitrary in the exerciſe of his authority, to allow any deviation or oppoſition among thoſe to whom his influence extended. Of this unamiable peculiarity of his character, inſtances occur under the articles Blandrata, Bolsec, and Castalio; but that which entails the greateſt diſgrace on his memory was his treatment of Servetus. Whilſt he was paſſing through Geneva, in order to ſeek an aſylum in Italy from the perſecution of Roman catholics, he was apprehended at the inſtigation of Calvin, tried on a charge of blaſphemy, condemned, and committed to the flames. The mere ſtatement of this fact is ſufficient to expoſe it; and no apology can be deviſed to extenuate it, but ſuch as ariſes from the intolerant ſpirit which generally prevailed, and which, for many ages, it was thought not only lawful but laudable to exerciſe againſt perſons who were deemed to hold unſcriptural and heretical opinions, conceived to be inconſiſtent with the unity of the church, and the ſafety of the civil ſtate.

The courſe of Calvin's life comprehended a great variety of paſtoral cares and literary labours; and it was terminated by ſickneſs and labour at comparatively an early period, in May 1564, as he was nearly compleating his 55th year. The character of this learned and active reformer has been groſsly calumniated by bigots of various deſcriptions; and more eſpecially by thoſe of the church of Rome. But it is juſtly obſerved by a liberal and candid biographer, that, whilſt his morals, in the ordinary ſenſe of the term, appear to have been irreproachable, his chief faults conſiſted in a reſemblance to thoſe uncharitable perſons who have cenſured and traduced him. His extraordinary talents have been acknowledged by the moſt eminent perſons of his age; and they were ſuch as would have rendered him a diſtinguiſhed ſcholar, if his attention had not been wholly, or at leaſt principally, devoted to theological ſtudies and eccleſiaſtical occupations. His writings are numerous. Beſides his "Inſtitute," he publiſhed learned commentaries upon moſt of the books of the New Teſtament, and upon the prophets in the Old. He refrained from commenting on the book of Revelation, much to his praiſe, according to the judgment of Scaliger and Bodin, becauſe he thought it impenetrably obſcure, and of dubious authority. Many zealous believers were offended by his applying to the temporal circumſtances of the Jews ſeveral ancient prophecies that have been thought to refer to the Meſſiah, and to furniſh arguments in confirmation of the Chriſtian cauſe. In this reſpect, however, he thought for himſelf, and eſcaped the odium of ſervile attachment to generally received opinions. To his other more elaborate works he added many controverſial pieces; and all his treatiſes were collected in 1560, in 9 vols. folio. His opinions, which are now better known than his writings, have been the ſubjects of innumerable controverſies. For an abſtract of them, ſee the next article. Gen. Dict. Moſheim. E. H. Vol. iv. Gen. Biog.

CALVINISM, the doctrine and ſentiments of Calvin, and of his followers, with regard to matters of religion.

Calviniſm ſubſiſts in its greateſt purity in the city of Geneva; and from thence it was firſt propagated into Germany, France, the United Provinces, and England. In

Germany, we may reckon among its chief patrons, Frederick III. elector Palatine, who, in 1560, removed from their paſtoral functions, the Lutheran doctors, and filled their places with Calviniſts; and, at the ſame time, obliged his ſubjects to embrace the tenets, rites, and inſtitutions of the church of Geneva. This order was abrogated in 1576 by his ſon and ſucceſſor Lewis, who reſtored Lutheraniſm; but in 1583, Calviniſm was again reſtored, under the government of the elector John Caſimir, and became triumphant. In France it was aboliſhed by the revocation of the edict of Nantes, in 1685. It has been the prevailing religion in the United Provinces ever ſince the year 1571. The theological ſyſtem of Calvin was adopted, and made the public rule of faith in England, under the reign of Edward VI.; and the church of Scotland was modelled by John Knox, the diſciple of Calvin, agreeably to the doctrine, rites, and form of eccleſiaſtical government, eſtabliſhed at Geneva. In England it has declined ſince the time of queen Elizabeth; though it ſtill ſubſiſts, ſome ſay a little allayed, in the articles of the eſtabliſhed church; and in its rigour in Scotland. See REFORMATION, and *Reformed* CHURCH.

The diſtinguiſhing theological tenets of Calviniſm, as the term is now generally applied, reſpect the doctrines of PREDESTINATION, or *particular* ELECTION and REPROBATION, *original* SIN, *particular* REDEMPTION, *effectual*, or, as ſome have called it, *irreſiſtible* GRACE in *regeneration*, JUSTIFICATION *by faith*, PERSEVERANCE, and the TRINITY. See each of theſe articles. See alſo ARMINIANS.

Beſides the doctrinal part of Calvin's ſyſtem, which, ſo far as it differs from that of other reformers of the ſame period, principally regarded the abſolute decree of God, whereby the future and eternal condition of the human race was determined out of mere ſovereign pleaſure and free will; it extended likewiſe to the diſcipline and government of the Chriſtian church, the nature of the euchariſt, and the qualification of thoſe who were intitled to the participation of it. Calvin conſidered every church as a ſeparate and independent body, inveſted with the power of legiſlation for itſelf. He propoſed that it ſhould be governed by preſbyteries and ſynods, compoſed of clergy and laity, without biſhops, or any clerical ſubordination; and maintained, that the province of the civil magiſtrate extended only to its protection and outward accommodation. In order to facilitate an union with the Lutheran church, he acknowledged a real, though ſpiritual, preſence of Chriſt in the euchariſt, that true Chriſtians were united to the man Chriſt in this ordinance, and that divine grace was conferred upon them, and ſealed to them, in the celebration of it; and he confined the privilege of communion to pious and regenerate believers. See EUCHARIST, &c. and LUTHERANISM.

In France the Calviniſts are diſtinguiſhed by the name of Hugonots; and, among the common people, by that of Parpaillots. In Germany they are confounded with the Lutherans, under the general title Proteſtants; only ſometimes diſtinguiſhed by the name Reformed.

CALVINISTS, *crypto*, a name given to the favourers of Calviniſm in Saxony, on account of their ſecret attachment to the Genevan doctrine and diſcipline. Many of them ſuffered by the decrees of the convocation of Torgaw, held in 1576. See *Form of* CONCORD.

The Calviniſts in their progreſs have divided into various branches, or leſſer ſects.

CALVINO, *Cape*, in *Geography*, is the moſt weſterly cape of the Morea, E. of Zante Iſland, and S.W. from the S. point of the entrance into the gulf of Lepanto.

CALVISANO, a town of the Breſſan, belonging to the ſtate of Venice; 12 miles S.S.E. of Breſcia.

CALVISIANA, in *Ancient Geography*, a place of Sicily between Agrigentum and Hybla, on the route from Lilybæum to Meſſina, according to the Itinerary of Antonine. M. d'Anville places it at a little diſtance N.W. of Gala, on the ſouthern coaſt.

CALVISIUS, SETHUS, or CALVITZ, in *Biography*, a German chronologer, was born at Groſleb, in Thuringia, in 1556, held the office of chantor at Leipſic, to which he was appointed in 1582, and died in 1615. His principal work was his "Opus Chronologicum," publiſhed at Frankfort in 1685, fol. In the compilation of this work, he adopted aſtronomical principles, and drew up aſtronomical tables, by means of which he fixed and compared different epochas. He alſo formed a ſyſtem of chronology from the beginning of the world to his own time; in which he inſerted the hiſtory of all ages, deſcribed by ſuch circumſtances, that even children might comprehend in their minds a continued ſeries or ſynopſis of hiſtory. Scaliger ſpeaks in terms of high commendation of this work, though the impreſſion of it was for ſome time prohibited by the governors of the univerſity of Leipſic. However, John Kepler the celebrated mathematician, and other perſons of leſs note, wrote againſt it. Calviſius publiſhed at Erford in 1610, in 4to., "Enodatio duarum Queſtionum, viz. circa Annum Nativitatis et Tempus Miniſterii Chriſti;" and in 1612, "Elenchus Calendarii Gregoriani, et duplex Calendarii melioris Forma," Franc. Marchionum, 4to. In this "Elenchus," he propoſes two points; firſt, to explode the Gregorian calendar by the principles of aſtronomy, and next to point out a truer and more convenient form of a calendar. Calviſius is reckoned among the heretics of the firſt rank in the "Index Expurgatorius," publiſhed at Madrid in 1667. According to Walter, in his "Muſical Lexicon," he was a very learned theoriſt, and good practical muſician; of which he has left ample proofs to poſterity in his ſhort treatiſe called "ΜΕΛΟΠΟΙΑ, ſive Melodiæ condendæ ratio, quam vulgò muſicam poeticam vocant, ex veris fundamentis extracta et explicata," 1592. This ingenious tract contains, though but a ſmall duodecimo volume, all that was known at the time, concerning harmonics and practical muſic; as he has compreſſed into his little book the ſcience of moſt of the beſt writers on the ſubject; to which he has added ſhort compoſitions of his own, to illuſtrate their doctrines and precepts. With reſpect to compoſition, he not only gives examples of concords and diſcords and their uſe in combination, but little canons and fugues of almoſt every kind then known.

He compoſed, in 1615, the 150th pſalm in twelve parts, for three choirs, as an Epithalamium on the nuptials of his friend Caſper Ankelman, a merchant of Hamburgh, and publiſhed it in folio at Leipſig, the ſame year. Several of his hymns and motets appear in a collection of Lutheran church-muſic, publiſhed at Leipſic, 1618, in eight volumes 4to. under the following title: "Florilegium portens CXV. ſelectiſſimas Cantiones, 4, 5, 6, 7, 8, voc. præſtantiſſimorum Auctorum." Some of theſe we have had the curioſity to ſcore, and have found the laws of harmony and fugue preſerved inviolate. Gen. Dict. Burney's Hiſt. Muſic, vol. iii.

CALVISSON, in *Geography*, a town of France, in the department of the Gard, half a league E. of Sommiéres, and three S.W. of Nimes.

CALVITI, a town of Naples, in the province of Calabria Citra; 11 miles E. of Cariati.

CALVITIES, or CALVITIUM. See BALDNESS.

CALUMET, in *Modern Hiſtory*, a myſtic kind of pipe uſed by the American ſavages as the enſign of peace, and for religious fumigation. This is a ſymbol of friendſhip univerſal among the people of North America, and the preſentation of it is an uſage of arbitrary inſtitution peculiar to them. The acceptance of it is a token of concurrence with the terms propoſed; and the refuſal as certain a ſignal of rejection. When this pipe is offered, even in the midſt of the rage of a conflict, the weapons of hoſtility drop inſtantly from their hands, and a truce enſues.

The calumet is a ſort of tobacco-pipe, made of red, black, or white marble. When they treat of war, the pipe and its ornaments are commonly red. The ſhank is decorated with rounds of feathers, and locks of hair, or porcupines quills: in it they ſmoke in honour of the ſun. M. Laſitau will have it to be the original CADUCEUS of Mercury, of which that uſed by the Greeks and Romans, with its wings and its ſerpents, was only the copy.

The calumet is the ſymbol and ſecurity of traffic; by it they pronounce life and death, peace and war: they alſo aſcribe to it a power of raiſing the ſouls of the dead.

Among the Indians, there is alſo a ſolemn rite, called the "dance of the calumet," which they perform on various occaſions. They are not allowed to waſh themſelves in the rivers at the commencement of ſummer, nor to taſte the new fruits, without performing it; and the ſame ceremony always confirms a peace, or precedes a war. In winter it is performed in their cabins, and in ſummer in the open fields. Having choſen a ſpot among trees, ſhaded from the heat of the ſun, they lay in the middle of it a large mat, and ſet upon it the monitor, or god, of the chief of the company. On the right hand of this image, they place the calumet, as their great deity, erecting around it a kind of trophy with their arms. Thoſe who are to ſing on the occaſion take the moſt honourable ſeat under the ſhade of the trees. When the company is arranged, each perſon, before he ſits down, ſalutes the monitor, by blowing upon it the ſmoke of their tobacco; then every one in rotation receives the calumet, and holding it with both hands, dances to the cadence of the vocal muſic, which is accompanied by the beating of a ſort of drum. During this exerciſe, he gives a ſignal to one of their warriors, who, taking a bow, arrow, and axe, out of the trophies above-mentioned, fights him; whilſt he defends himſelf with the calumet only; and both of them continue the paſtime of dancing. When this mock-engagement is concluded, he who holds the calumet makes a ſpeech, recounting the battles he has fought, and the priſoners he has taken, and then receives a cloak, or ſome other preſent, from the chief of the ball. He then reſigns the calumet to another; who, having acted a ſimilar part, delivers it to a third perſon; and thus in rotation, till at laſt the inſtrument returns to the perſon who began the ceremony; by whom it is preſented to the nation invited to the feaſt as a mark of friendſhip, and a confirmation of their alliance, when this is the occaſion of the entertainment.

CALUMET, *Grand*, in *Geography*, a portage of Lower Canada, in North America, on the northern bank of the river Utawas. This is the longeſt carrying place on this river, and is about two thouſand and thirty-five paces. It is a high hill or mountain. From the upper part of this portage the current is ſteady, and is only a branch of the Utawas river, which joins the main channel, that keeps a more ſouthern courſe, at the diſtance of 12 computed leagues. Six leagues further it forms lake Coulonge, which is about four leagues in length; from whence it proceeds through the channels of the Allumettes to the portage, where part of the lading is taken out, and carried 342 paces. Then ſucceeds the portage des Allumettes, which is but 25 paces, over a rock difficult of acceſs, and at a ſhort diſtance from lake Coulonge. From portage de Chenes to this ſpot is a fine deer hunting country, and the land in many parts fit for cultivation. From hence the river ſpreads wide, and is full of iſlands, with ſome current for ſeven leagues, to the beginning of "Riviere Creuſe," or DEEP RIVER. Grand Calumet lies in N. lat. 45° 40′. W. long. 77° 10′. Mackenzie's Voyages. Introd. p. 33.

CALUMNY, the crime of accuſing another falſely and knowingly of ſome heinous offence. *Calumnia eſt malitioſa & mendax informatio.*

It is an ancient maxim, which experience ſhews us to be too well founded: *Audacter calumniare, ſemper aliquid hærebit.*

CALUMNY, *oath of*, *Juramentum*, or rather *Jusjurandum calumniæ*, among civilians and canoniſts, was an oath which both parties in a cauſe were obliged to take; the plaintiff, that he did not bring his charge, and the defendant, that he did not deny it, with a deſign to abuſe each other, but becauſe they believed their cauſe was juſt and good; that they would not deny the truth, nor create unneceſſary delays, nor offer the judge or evidence any gifts or bribes. If the plaintiff refuſed this oath, the complaint or libel was diſmiſſed; if the defendant, it was taken *pro confeſſo*.

This cuſtom was taken from the ancient athletæ, who, before they engaged, were to ſwear they had no malice, nor would uſe any fraudulent or unfair means for overcoming the other. The *juramentum calumniæ* is much diſuſed as a great occaſion of perjury. Anciently the advocates and proctors alſo took this oath; but of late it is diſpenſed with, and thought ſufficient that they take it once for all at their firſt admiſſion to practice.

CALUMNIÆ, *judicium*, was an action brought againſt the plaintiff in a court for a falſe and malicious accuſation. When an accuſer did not prove his charge, nor ſeemed to have ſufficient or probable grounds for bringing any, the judges in pronouncing ſentence uſed the formula *calumnioſus es*; which gave the defendant a right to bring an action of calumny; the penalty of which was *frontis inuſtio*, or burning on the forehead. See ACCUSATION.

CALUMNY, in the *Arts*, was admirably perſonified by Apelles. This celebrated painter was accuſed of having conſpired againſt Ptolemy, king of Egypt; and being delivered from the danger that threatened him, he determined to avenge himſelf of the calumny by a picture, which was always held in high eſtimation. On the right was ſeated a man with large ears, reſembling Midas; he ſtretched out his hand towards Calumny, who approached him; and near him were placed two female figures, thoſe of Ignorance and Diffidence. On the other ſide ſtood Calumny, who was a beautiful female, that appeared agitated and enraged: ſhe held in her left hand a flaming torch, and with her right ſhe dragged by the hair a youth, lifting his hands towards the heavens, and calling the gods to witneſs in his favour. Before her moved a pale and deformed man, with piercing eyes, who ſeemed to have juſt recovered from a long illneſs: this was Envy. Two other females converſed with Calumny; theſe were Concealment and Deceit. Another female followed, cloathed in black, with tattered garments, which was Repentance: ſhe turned her head backward, diſſolved in tears, and looked with ſhame on Truth, who approached her. Lucian, in his "Dialogue againſt Calumny," has tranſmitted to us this model of moral allegory.

CALVORD, in *Geography*, a town of Germany, in the circle of Lower Saxony, and duchy of Magdeburg; 24 miles N.W. of Magdeburg.

CALUPENA, in *Ancient Geography*, a country of Aſia, on the frontiers of the Leſſer Armenia, and of the country of

Lanaſena, according to Strabo (vol. ii. p. 838,) who ſays, that it belonged to the prieſt of the temple of Zela.

CALUS, *Eſbet*, a river of Aſia, whoſe mouth was S.W. of the town of Rhizæum, in a bay of the Euxine ſea, at ſome diſtance E. of Trapezus.

CALUSIO, in *Geography*, a town of Italy, in the principality of Piedmont; 5 miles N. of Chivaſſo.

CALW, a town of Germany, in the circle of Swabia, and duchy of Wurtemburg, on the Nagold, having a manufacture of ſerges and of china; 16 miles W. S. W. of Stuttgard, and 24 E.S.E. of Raſtadt.

CALX. See CALCINATION and LIME.

CALX *of Antimony*. See ANTIMONY.

CALX *of braſs*, is called ÆS USTUM.

CALX *jovis*, the *calx* of TIN, called PUTTY.

CALX *lunæ*, the *calx* of SILVER.

CALX *martis*, the crocus or ſaffron of IRON.

CALX *mercurii*, precipitated MERCURY.

CALX *nativa*, in *Natural Hiſtory*, a native marley earth, which, without burning, has ſome of the qualities of the artificial lime, and was called by the ancients, *gypſum tymphaicum*. See CALCAREOUS EARTHS.

CALX *nitrata*. See NITRE *of lime*.

CALX *ſaturni*, is ceruſs calcined with ſpirit of vinegar, or in the ſun. See CERUSSE.

CALX *ſaturni*, is alſo uſed for MINIUM or RED LEAD.

CALX *ſolis*, denotes calcined GOLD.

CALX *terræ*, a denomination given by Paracelſus to the bolar and argillaceous earths. He has alſo given the name of calx to the chalky matter formed in the joints of gouty perſons.

CALX *veneris*, VERDIGRISE.

CALX *viva*, quick-lime, that on which no water has been caſt ſince its burning, in oppoſition to *calx extincta*, that ſlacked by the affuſion of water. See LIME.

CALX *viva philoſophorum*, denotes that made of quick-ſilver.

CALX, in *Anatomy*. See CALCANEUM.

CALYBE', in *Ancient Geography*. See CABYLE.

CALYBE', in *Mythology*, an ancient prieſteſs of the temple of Juno, the form of which is aſſumed by the fury Alecto, in the Æneid, in addreſſing Turnus.

CALYBE, in *Ornithology*, *Calybé de la Nouvelle Guinée*, Buffon, the blue green bird of paradiſe, deſcribed by Gmelin under the title of *Paradiſea viridis*.

CALYBITES, the inhabitants of a cottage, an appellation given to divers ſaints on account of their long reſidence in ſome hut, by way of mortification. The word is formed from *καλυπτω*, *tego*, *I cover*; whence *καλυβη*, *a little cot*.—The Romiſh church commemorates St. John the *calybites* on the 15th of December.

CALYCADNUS, in *Ancient Geography*, a river of Aſia, in Cilicia Trachea; whoſe mouth was between the two promontories of Zephyrium and Sarpedon. The ſame name is alſo given by Livy and Appian to a promontory of Aſia, ſuppoſed to be the ſame with Zephyrium.

CALYCANTHEMÆ, in *Botany*, (from *καλυξ*, *calx*, and *ανθος*, *flower*,) the fortieth of the natural orders of Linnæus, in his Philoſophia Botanica, and the ſeventeenth of his poſthumous lectures, publiſhed by Giſeke. In the Philoſophia Botanica, it contains the following genera, epilobium, œnothera, juſſiæa, ludvigia, oldenlandia, iſnardia, ammannia, peplis, lythrum, glaux, and rhexia. In the poſthumous lectures, oldenlandia is withdrawn, and the following added: gaura, griſlea, mentzelia, looſa, frankenia, melaſtoma, and oſbeckia. In ſome of theſe genera the calyx is ſuperior, and in others inferior; but in all it ſupports the ſtamens, and if there be a corolla, of courſe that likewiſe. The name is derived from this circumſtance, but it is not well-choſen, as many plants which have the ſame character are not included under it.

It is alſo the ſeventh order of the fourteenth claſs in the ſyſtem of Ventenat, where, though founded on the ſame general idea, it is ſtill leſs comprehenſive. Its genera are pemphis, ginoria, lawſonia, lythrum, aciſanthera, parſonia, cuphea, iſnardia, ammania, glaux, and peplis. In all theſe the calyx is inferior; and the corolla, when preſent, is inſerted upon it, alternating with its diviſions.

CALYCANTHUS, in *Botany*, (from *καλυξ*, *calyx*, and *ανθος*, *a flower*, ſo called becauſe the calyx reſembles a corolla.) Linn. gen. 639. Schreb. 870. Willd. 1005. Juſſ. 342. Vent. vol. iii. p. 357. (Butneria, Duham. Baſteria, Miller, Beureria, Ehret.) Claſs and order, *icoſandria polygynia*. Nat. ord. undetermined by Linnæus. *Roſaceæ*, Juſſ. Allied to the *roſaceæ*, Vent.

Gen. Ch. *Cal.* perianth one-leafed, pitcher-ſhaped, deeply divided, ſegments numerous, linear-lanceolate, coloured. (Caduceous, Vent.) *Cor.* petals numerous, ſtrap-ſhaped, acuminate, attached to the calyx within its diviſions, and exactly reſembling them. *Stam.* twenty, much ſhorter than the petals; anthers oblong, erect, furrowed. *Piſt.* germs numerous, ſuperior; ſtyles awl-ſhaped, compreſſed, the length of the ſtamens; ſtigmas glandulous. *Per.* none, except the bottom of the calyx, which thickens, becomes ſucculent, and takes the form of a berry. *Seeds* many, tailed.

Eſſ. Ch. *Calyx* one-leafed, pitcher-ſhaped, with coloured ſegments. *Petals* reſembling the ſegments of the calyx. *Seeds* many, tailed, within a ſucculent calyx.

*Obſ.* Linnæus gives the flower no corolla, but a calyx with many diviſions in two concentric ranks, all reſembling petals; and Schreber and Martyn adopt his ideas. But we have preferred the deſcription of La Marck and Ventenat, Juſſieu having obſerved, that the inner rank probably conſiſts of petals; and Linnæus himſelf having, perhaps, incautiouſly, doubtleſs inconſiſtently, admitted the term petals into both his ſpecific characters. Sp. 1. C. *floridus*, Carolina all-ſpice, Linn. Sp. pl. La Marck, Illuſ. Pl. 445. fig. 1. (Butneria, Duhamel, Tab. 45. Baſteria, Mill. icon. 60. Beureria, Ehret. Tab. 13. Frutex corni foliis, Cateſb. Car. 1. p. 46. Tab. 46.) "Petals longer than the diviſions of the calyx." A ſhrub three or four feet high, or more in its native country. *Stem* irregularly branched, covered with a brown aromatic bark. *Leaves* oppoſite, petioled, egg-ſhaped, acute, entire, on ſhort petioles. *Stipules* none. *Flowers* of a duſky purple colour, about an inch and a half or two inches in diameter; the petals incurved at the top; peduncles ſhort, ſolitary, pubeſcent. A native of Carolina. Boſc aſſerts, from his perſonal obſervation in Carolina, that Linnæus has confounded two diſtinct plants under one name. Both have oppoſite, egg-ſhaped, lanceolate leaves, without ſtipules, but thoſe of one are pubeſcent and large, of the other, ſmooth and ſmaller; the flowers of the former are alſo larger, of a deeper red colour, and have a ſtrong unpleaſant ſmell, which thoſe of the latter have not. Profeſſor Martyn mentions two varieties, the one with oblong, the other with roundiſh, egg-ſhaped leaves, but they do not correſpond with Boſc's two ſpecies, the latter of which does not appear to be known in England. The former was introduced into our gardens, by John Cateſby, ſo early as 1726. It will thrive in the open air, if planted in a warm ſituation and dry ſoil. It is propagated by laying down the young branches, which ſhould be done in Autumn; in the ſpring twelvemonth after, the layers ſhould be ſeparated from the parent ſtock, and ſet where they are deſigned to remain. Some old tanners' bark ſhould be laid on the ſurface to keep out the froſt while the plants are young. Boſc informs us, that the flowers and ends of the branches infuſed in brandy make a pleaſant liquor, and that the ſeeds are thought, in America, to be poiſonous to dogs and foxes. 2. C. *præcox*, Linn. Sp. La Marck Illuſt. Pl. 415. fig. 2. (Obai or Robai, Kæmpf. Amœn. 878. Tab. 879.) "Petals ſhorter than the diviſions of the calyx." *Leaves* egg-ſhaped lanceolate. *Flowers* appearing before the leaves, yellow; petals ſmall, beſprinkled with red ſpots. *Fruit* longer, ſcaly and rough. *Seeds* five or ſix, which ſoon loſe their tail, and reſemble French beans. A native of Japan and China, introduced into England in 1771.

CALYCERA, (from καλυξ, *calyx*, and κερας, a *horn*.) Willd. Cavan. ic. 4. p. 34. Tab. 358. Claſs and order, *ſyngeneſia ſegregata*.

Eſſ. Ch. Common calyx many-leaved; proper calyx five-toothed. Florets tubular, male and hermaphrodite. Receptacle chaffy. Seeds naked.

Sp. C. *herbacea*. *Root* fungous. *Stems* a foot high, erect, ſimple, ſmooth, round, hollow. *Leaves* linear-lanceolate, pinnatifid, toothed; ſtem ones nearly ſeſſile; radical ones on long petioles. *Flowers* compound, globular, terminal; barren and fertile florets intermixed; teeth, in the barren florets, egg-ſhaped, acute, very ſhort; in the fertile ones, lanceolate-awl-ſhaped, twice the length of the corolla. *Seed* ſingle, naked, at the bottom of the calyx. *Receptacle* ſomewhat globular. A native of Chili.

CALYCIFLORÆ, a natural order formed by Linnæus for four genera, Oſyris, Trophis, Hippophæ, and Elœagnus; but, as we learn from Giſeke, afterwards aboliſhed.

CALYCIFLORUS in *Zoology*, a ſpecies of BRACHIONUS, firſt deſcribed by Baker in his Eſſays on the Microſcope, and ſince by Profeſſor Pallas. It is defined by the latter as being of a ſimple form, calyculate, with the ſhell crenated behind, and the upper lip of the mouth four-toothed. Inviſible to the naked eye. Found in water.

CALYCINA, in *Entomology*, a ſpecies of ARANEA, the abdomen of which is globoſe, and of a pale, yellowiſh colour. The inſect is thus deſcribed by Linnæus in his Fauna Suecica, as a Swediſh ſpecies. Scopoli calls it aranea Kleynii. This kind of ſpider ſecretes itſelf in the calyces of flowers from which the corolla has fallen, and faſtens on the flies that are tempted to the calyces in ſearch of the nectareous juices.

CALYCISTÆ, in *Botany*, a name given by Linnæus to thoſe botaniſts who have arranged plants from a regard chiefly or ſolely to their calyx. Magnol and Linnæus himſelf are the only authors mentioned who have attempted this method.

CALYCLE, a term invented by Vaillant to expreſs a ſeries of leaves ſurrounding the baſe of the calyx, generally ſhorter, of a different ſhape, and making a kind of double calyx; as in crepis, dianthus, malva, &c. Linnæus in his Philoſophia Botanica calls ſuch a calyx auctus; but in his practical works he is by no means uniform in his manner of expreſſing this circumſtance. In the Syſtema Naturæ, he deſcribes the calyx of crepis and other kindred genera as calycled; but in the Genera Plantarum he ſtiles it ſometimes auctus and ſometimes duplex or double. This latter term he applies to the calyx of malva, &c. That of dianthus he calls ſcaly. The term is alſo uſed by Linnæus to denote the ſmall permanent perianth which crowns the ſeed of ſcabioſa, arctotis, and ſome other genera, and is ſuppoſed, like the down attached to the ſeed of moſt ſyngeneſious plants, to facilitate its diſperſion. According to Gærtner, a ſeed is calycled when its cruſt is extended above its vertex, ſo as to form a one-leafed cup: it is either entire as in tanacetum, pyrethrum, dipſacus, &c. or halved as in melampodium and a few others. If there be more than one leaf it is conſidered by him as a different kind of pappus which he calls chaffy. The term calycle is therefore employed by him leſs extenſively than it is by Linnæus. See his general Introduction, p. 126.

CALYCOPTERIS, a generic name given to a ſhrub figured by La Marck in his Illuſtrations, which belongs to decandria monogynia of the Linnæan ſyſtem. But there is no article under that name in the alphabetical part of the Encyclopedie; and as the letter-preſs of the Illuſtrations is not completed, we are not able to determine its proper generic character, nor of what country it is a native.

CALYDERMUS, (from καλυξ, *calyx*, and δερμα, a *ſkin or thin rind*) a genus formed by the authors of the Flora Peruvenſis for the atropa phyſaloides of Linnæus, which differs from the other ſpecies in having a dry five celled berry, and a calyx with arrow-heart-ſhaped diviſions, covering the fruit.

CALYDNA INSULA, in *Ancient Geography*, a ſingle iſland according to Steph. Byz. and CALYDNÆ *Inſulæ*, a group of iſlands, according to Homer, who ſeems to place them near the iſland of Rhodes. Some have thought that by this general appellation the poet deſigned to expreſs the Sporades. Strabo, in ſpeaking of their honey, places them near Tenedos; and M. d'Anville ſuppoſes, that they are two rocks, which are ſtill found, one before and the other to the right of the port of Tenedos.

CALYDON, a city of Ætolia, pleaſantly and commodiouſly ſeated on the river Evenus, which paſſed through it. This city, which ſeems to have continued for ſome time the reſidence of the ancient Ætolian kings, was built by Calydon, the ſon of Ætolus, from whence the kingdom was called Calydonia, though it afterwards reſumed its ancient appellation. Hercules came to this city after he had left Peloponneſus; and though he had a numerous ſpurious brood, ſcattered over all Greece, yet, deſirous of legitimate iſſue, he is ſaid to have married Dejanira, the daughter of Œneus, king of the country, and father to Meleager; and with a view of ingratiating himſelf with the Ætolians, to have turned the current of the river Achelous, or to have made ſuch improvements in its channel, as to have given riſe to the fable of his having vanquiſhed it in ſingle combat. Calydon was ſituated near the foreſt of that name, where Meleager, accompanied by the nobleſt youths of Greece, ſlew the famed Calydonian boar. This fierce and monſtrous animal had done ſo much miſchief in the neighbourhood, that Meleager, king of the country, who kept his court at Calydon, was forced to call to his aſſiſtance a great number of the moſt diſtinguiſhed perſons of Greece in order to deſtroy it. The chief of theſe were Theſeus, Telamon, Peleus, Pollux, and Iolaus, all of them the faithful companions of Hercules, beſides a number of other heroes. To theſe we may add the famous Arcadian princeſs Atalanta, who behaved with ſuch uncommon courage and intrepidity upon this occaſion, that Meleager became enamoured with her, and married her. If we may credit Pauſanias, (Arcad. cap. 46.) one of the tuſks of this boar, which was preſerved in the temple of Bacchus, in the imperial gardens, was above a yard long, and therefore his ſize muſt have been very great. Some imperial Greek medals were ſtruck in the city of Calydon.

CALYMERE *Point*, in *Geography*, lies on the ſouthern extremity of the eaſt coaſt of the Carnatic country, in Hindooſtan, near Negapatam. N. lat. 10° 20′. E. long. 79° 54′ 30″.

CALYMNA, in *Ancient Geography*, an iſland of the Mediterranean ſea, upon the coaſt of Aſia, before Carpathum, according to Pliny. Ovid ſays, that it produced abundance of honey. It was one of the Sporades, S.W. of Leros, and N.W. of Cos. See Calamo.

CALYNDA. See Calinda.

CALYPARIS, *Fiume Caſſibili*, a ſmall river of Sicily, on the eaſtern coaſt.

CALYPLECTUS, in *Botany*, (from καλυξ, *calyx*, and πλεκτος, *plaited* or *folded*.) Flor. Peruv. Pl. 13. Claſs and order, *icoſandria monogynia*.

Gen. Ch. *Cal.* perianth bell ſhaped, leathery, caducous, with from ten to twelve plaits, and from ten to twelve teeth. *Cor.* petals from ten to twelve, attached to the folds of the calyx. *Stamens* about thirty. *Piſt.* germ ſuperior, globular, ſtriated; ſtigma ſimple. *Peric.* capſule globular, one-celled, longitudinally ſtriated in its upper part, opening irregularly. *Seeds* numerous, flat, membranous.

CALYPSO, in *Entomology*, a ſpecies of Papilio, (Dan. Cand.) ſo named by Fabricius in his *Species Inſectorum*, and by other writers. This butterfly is ſpecifically diſtinguiſhed by having the wings roundiſh; dot, and tip of the anterior pair black; poſterior ones yellowiſh beneath, and the margin dotted with black. Inhabits Sierra Leona.

Calypso, in *Fabulous Hiſtory*, the daughter of Oceanus and Thetis, or, according to Homer, the daughter of Atlas, who reigned over the iſland of Ogygia in the Ionian Sea; hence called the "Iſland of Calypſo." Here ſhe received Ulyſſes on his return from the Trojan expedition, and detained him ſeven years, offering to make him immortal if he eſpouſed her. But Ulyſſes, retaining in recollection his beloved Penelope, preferred a reſidence in the iſle of Ithaca, to all the advantages which Calypſo propoſed, and took his leave of the goddeſs, though not without regret. The name of Calypſo is derived from καλυπτειν, to conceal. Many different iſlands, very remote from one another, have been aſſigned to Calypſo; among which, beſides Ogygia, are Aea, and that which bears her name before Puzzuoli.

CALYPTRA, in *Botany*, (καλυπτρα, *a veil*, from καλυπτω, *to cover*,) a term uſed by old authors for that kind of ſeed covering, which Linnæus calls arillus; but afterwards transferred by Dillenius and others to that fugacious conical covering which inveſts the capſules of moſſes before they arrive at maturity. Linnæus, who miſtook the capſule for an anther, conſidered it as a ſpecies of calyx. Hedwig at firſt regarded it as the corolla, but was afterwards convinced that it is properly part of the piſtil, and that its firſt office is to ſtrengthen the attachment of the ſtyle to the germ. But as, from his own deſcription, in its early ſtate it inveſts the eſſential parts of the fructification, it is, as Linnæus made it, properly a ſpecies of calyx. When the germ becomes enlarged, the calyptra is torn all round from the baſe of the receptacle, and carried up by the capſule.

CALYPTRANTHES, from καλυπτρα, *a veil*, and ανθος, *a flower*,) Willdenow, 974. Schreb. 845. Swartz. Prod. 79. Claſs and order, *icoſandria monogynia*. Nat. Ord. *Myrti*.

Gen. Char. *Cal.* perianth one-leafed, bell-ſhaped, truncate, without teeth, or very ſlightly four-toothed, ſuperior, permanent; covered before the time of flowering with a round, concave, deciduous operculum or lid. *Cor.* none. *Stam.* filaments numerous, capillary, inſerted within the rim of the calyx; anthers roundiſh, double, ſmall. *Piſt.* germ roundiſh, faſtened to the bottom of the calyx: ſtyle, ſimple, thread-ſhaped, inflexed, the length of the ſtamens; ſtigma obtuſe. *Peric.* berry globular or oblong, crowned with the calyx. *Seeds* from one to four, ſomewhat angular.

Eſſ. Ch. *Calyx* ſuperior, truncate, covered till the ſtamens and piſtil become mature, with an entire deciduous lid. *Corolla* none. *Berry* one-celled. *Seeds* from one to four. Obſ. It differs from Eucalyptus in having a berry, not a capſule.

Species, 1. C. *chytraculia*, Willd. Swartz. Prod. 79. Fl. ind. occid. 2. p. 921. (Myrtus Chytraculia, Linn. Sp. Chytraculia, Brown Jam. 239. tab. 37. fig. 2.) "Peduncles terminal, panicled, trichotomous, downy; leaves egg-ſhaped, attenuated at the top." A tree. *Leaves* ſmooth, oppoſite. *Lid* faſtened to the calyx laterally, but it afterwards turns back, and then the filaments come out, which before had been twiſted and concealed. It is reckoned an excellent timber wood, but ſeldom exceeds 14 or 15 inches in diameter. A native of Jamaica, where it is called baſtard-green-heart. 2. C. *zuzygium*, Willd. Swartz. Prod. 79. Fl. ind. occ. 2. p. 919. (Myrtus zuzygium, Sp. Pl. Zuzygium, Brown. Jam. 240. tab. 7. fig. 2.) "Peduncles axillary, trichotomous, ſpreading; leaves egg-ſhaped, obtuſe; branches dichotomous." A buſhy ſhrub, 10 or 12 feet high. *Style* longer than the ſtamens; ſtigma acute. *Berries* black. *Seeds* four, ſmooth, ſlightly angular, one or two only generally coming to maturity. A native of Jamaica. This and the preceding were introduced into England in 1778 by Dr. Thomas Clark. 3. C. *rigida*, Willd. Swartz. Prod. 80. Fl. ind. occ. 2. p. 923. "Peduncles ſolitary, about three-flowered: leaves egg ſhaped, acute, convex, veinleſs, rigid." A ſhrub. A native of Jamaica. 4. C. *guineenſis*, Willd. "Peduncles axillary and terminal, in corymbs; leaves oblong, attenuated at the top and bottom, reticulated." A ſhrub. *Leaves* oppoſite, entire, ſhining on their upper ſurface. *Corymbs* divaricated; peduncles two-flowered. A native of Guinea.

Obſ. Profeſſor Martyn has adopted the idea of Schreber, in conſidering the Jambolifera of Linnæus and the Calyptranthes of Swartz as one genus, and has accordingly added the Jambolifera pedunculata of Linnæus and the J. odorata and reſinoſa of Loureiro. Willdenow concurs with him, and has alſo adopted into this genus Eugenia caryophyllifolia of La Marck, quoting Myrtus cumini of Linnæus as a ſynonym. But as all theſe plants are expreſsly ſaid to be furniſhed with petals, and as the firſt three have only eight ſtamens, they cannot belong to Calyptranthes, while its generic characters remain as they now ſtand. The genus Jambolifera was formed by Linnæus for a ſingle ſpecies, to which he attributed only eight ſtamens, and which he ſuppoſed to be the ſame as the Jambolana of Rumphius, and the Caryophyllus tanga of Plukenet; but La Marck aſſures us that he has in his Herbarium two ſpecies, one of which is inconteſtibly the plant of Rumphius, and the other that of Plukenet, which Linnæus erroneouſly ſuppoſed to be one and the ſame, both which have many ſtamens. Gærtner alſo, who has continued the genus, deſcribes it as having many ſtamens, and ſuppoſes that Linnæus formed his generic character from an incomplete ſpecimen. The two new ſpecies added by Loureiro are indeed ſtated to have only eight ſtamens; but if they agree with the original ſpecies of Linnæus in all their other characters, a difference merely in number will not warrant their ſeparation. They may all be properly placed under Eugenia, which, as Dr. Smith has obſerved (Linn. Tranſ. v. 3. p. 281.), will include alſo Gærtner's Syzygium; but in that caſe we muſt attribute to the genus an indefinite number of ſtamens from eight to forty or more.

CALYTRIPLEX, in *Botany* (ſo called from its treble calyx). Flora Peruv. Pl. 19. Claſs and order, *didynamia angioſpermia*.

Gen. Ch. *Calyx* treble, permanent; outer one conſiſting of two awl-ſhaped leaflets; middle one with three egg-ſhaped, acute diviſions; inner one of two lanceolate leaflets. *Cor.* irregular; tube ſhort; border with five nearly round ſegments; the two upper ones larger. *Stam.* four. *Piſt.* germ ſuperior, compreſſed; ſtyle thread-ſhaped, declining, the length of the ſtamens; ſtigma capitate. *Peric.* capſule egg-ſhaped, two-celled, two-valved. *Seeds* numerous, ſmall, furrowed, ſtriated; receptacle fixed to the valves.

Eſſ. Ch. *Calyx* treble. An herbaceous plant, native of Peru.

CALYX, or Calix, in a general ſenſe, denotes a cup. See Chalice.

Calyx, in *Ancient Aqueducts*, denoted a brazen module or cup, put over a head or caſtellum, to which pipes were fitted.

Calyx, in *Botany*, καλυξ, *a covering*, from καλυπτω. The word is uſed by Greek writers for a roſe bud, in which the proper flower or corolla of modern botaniſts is not opened, but lies concealed under an envelope. It is thus explained by Suidas, καλυξ, ανθος ῥοδου μεμυκος: the flower of the roſe ſhut up. And again, καλυκας, συριγγας, ῥοδα κεκαλυμμενα, which clearly points out the etymology. Heſychius, long before him, had given the ſame general idea. Καλυξ, το ανθος του ῥοδου, το μη εκπετασθεν: the flower of the roſe not expanded. Aquila, ſtill earlier, in his verſion of Iſaiah, ch. xxxv. 1. had tranſlated the Hebrew word כחבצלת, καλυξ, which, Jerom ſays, is a better rendering than κρινον of the Septuagint, or lilium of the Vulgate. Florebit ut lilium, ſive ut ſignificantius expreſſit Aquila, ως καλυξ, quam nos tumentem roſam, & necdum foliis dilatatis poſſumus dicere. It ſhall flouriſh as a lily, or as Aquila more ſignificantly expreſſes it, as a calyx, or ſwelling roſe, whoſe flower-leaves are not yet expanded.

By theſe writers the bud itſelf, in its entire ſubſtance, is called a calyx: though the admiſſion of συριγγας, by Suidas, as a ſynonym of καλυκας, may ſeem to imply only the envelope, to which the term has been applied by modern botaniſts. According to Ray, it is the caſe (folliculus) in which, firſt the flower, and afterwards the ſeed of herbaceous plants, and the fruit of trees is encloſed: but the latter part of the definition muſt certainly be received, with numerous exceptions.

Through a ſimilarity in ſound, and in many caſes, a reſemblance in form, it was very early confounded with calix, a cup; but as it is almoſt univerſally ſpelt with a y in the laſt ſyllable, its derivation and proper meaning cannot be doubted. It is the envelope caſe or ſheath in which the tender flower lies for a time concealed, and by which it is, in moſt caſes, afterwards ſupported and protected.

Linnæus has followed Cæſalpinus in conſidering the calyx as a prolongation of the cortex, or outer bark of the plant; and has diſtinguiſhed it into ſeven different kinds: 1. A perianth, contiguous to the other parts of the fructification. This is frequently called empalement or flower-cup by Engliſh writers, and to it, as profeſſor Martyn well obſerves, ſhould the term, cup, if admitted at all, be confined. 2. An involucre, remote from the flower, as in many umbelliferous plants. 3. An amentum or catkin, from a common, chaffy, gemmaceous receptacle. 4. A ſpathe burſting longitudinally. 5. A glume, formed of valves embracing the ſeed. 6. A calyptra, covering the capſules of moſſes like a hood. 7. A volva, a membranaceous covering to the fructification of the fungi. See thoſe words. The involucre is rather a number of bractes; and the amentum, a ſpecies of infloreſcence.

CALYXHYMENIA. Ortega Decad. Bot. Flor. Peruv. Pl. 75. Claſs and order, *triandria monogynia.*

Gen. Ch. *Cal.* with five diviſions. *Cor.* bell-ſhaped; border with five plaited diviſions. *Stam.* three. *Piſt.* germ ſuperior: ſtyle curved; ſtigma capitate. *Peric.* drupe egg-ſhaped, one-ſeeded, encloſed in the calyx.

Four ſpecies of this genus are figured in the Flora Peruvienſis, which are all herbaceous plants with jointed ſtems, and oppoſite, petioled, egg-ſhaped, entire leaves. They are nearly allied to mirabilis: and according to Boſc, from whom we are obliged, not having the Flora Peruvienſis at hand, to tranſlate this article, and whoſe information, as uſual, is mutilated and unſatisfactory; there ought to be added to them the mirabilis viſcoſus of Cavanilles, which has been formed into a diſtinct genus by Tuna, under the name of Vitmania, and by l'Heretier, under that of Oxybaphus.

CALZADA, in *Geography*, a town of Spain, in Old Caſtile, once the ſee of a biſhop, united to that of Calahorra; 40 miles W. of Calahorra. N. lat. 42° 12′. W. long. 2° 47′.

CAM, or Grant, a river of England, which paſſes by Cambridge, and joins the Ouſe, three miles ſouth from Ely.

Cam, one of the ſmaller Virgin iſlands in the Weſt Indies, N. lat. 18° 20′. W. long. 63° 25′.

Cam's *Bank*, lies on the coaſt of Flanders, W. of the Broer's bank, within which a ſhip may run through and ride by the land in all winds.

CAMA, or Cameia, in *Ancient Geography*, a town of Aſia in Armenia; the chief city of the Manichees.

CAMAC, Porto, in *Geography*, lies on the north ſide of the iſland of Candia, to the S. of the Archipelago iſlands, and on the E. ſide of Cape St. John, having ſeveral iſlands in its mouth.

CAMACÆ, and Camæ, in *Ancient Geography*, the denomination of diſtinct people, claſſed by Pliny among the Scythian nations on this ſide of mount Imaus.

CAMÆA, in *Natural Hiſtory*, the name of a genus of the ſemipellucid gems, the characters of which are theſe: they are obſcurely tranſparent ſtones approaching to the onyx ſtructure, being compoſed of zones, and formed on a cryſtalline baſis, but having their zones very broad and thick, and laid alternately on one another with no other matter between them.

Of this genus we have four known ſpecies:

1. The dull-looking onyx, with broad black and white zones. This is the camæa of the moderns, and the Arabian onyx. It is found in Egypt, Arabia, Perſia, and the Eaſt Indies. 2. The dull broad-zoned green and white camæa, or the jaſpicamæo of the Italians: found in the Eaſt Indies, and in ſome parts of America. 3. The hard camæa, with broad white and cheſnut-coloured veins. 4. The hard camæa with bluiſh, white, and fleſh-coloured broad veins, being the ſardonyx of Pliny's time, brought only from the Eaſt Indies.

CAMAHA, in the *Materia Medica*, a name given by Avicenna and others to the large truffles found in the deſarts of Numidia, and many other parts of Africa, in great abundance. Theſe are white on the outſide; the modern Africans call them *terſon*, and are very fond of them; they eat them ſtewed with milk, water, and ſpices, and account them wholeſome and nutritive.

CAMAIEU, or Camayeu, in *Mineralogy*, a word uſed to expreſs a peculiar ſort of onyx: alſo by ſome to expreſs a ſtone, whereon are found various figures, and repreſentations of landſcapes, &c. formed by a kind of *luſus naturæ;* ſo as to exhibit pictures without painting. The word comes from *camehuia*, a name the Orientals give to the onyx, when they find, in preparing it, another colour; thus expreſſing *a ſecond ſtone.* It is of theſe camaieux Pliny is to be underſtood when he ſpeaks of the manifold picture of gems, and the party-coloured ſpots of precious ſtones: *Gemmarum pictura tam multiplex, lapidumque tam diſcolores maculæ.* Plin. Hiſt. Nat. lib. ii. c. 93.

Camaieu is alſo applied by others to thoſe precious ſtones, as onyxes, cornelians, and agats, whereon the lapidaries employ their art to aid nature, and perfect thoſe repreſentations. See Camæa.

Camaieu is alſo frequently applied to any kind of gem, whereon figures may be engraven either indentedly, or in relievo. In this ſenſe the lapidaries of Paris are called in their ſtatutes *cutters of camayeux.* A ſociety of learned men at Florence undertook to procure all the *cameos* or *camayeux,* and intaglios in the great duke's gallery, to be engraven; and began to draw the heads of divers emperors in *cameos.*

Camaieu is alſo uſed for a painting, wherein there is only one colour; and where the lights and ſhadows are of gold, wrought on a golden or azure ground. When the ground is yellow, the French call it *cirage;* when grey, *griſaile.* This kind of work is chiefly uſed to repreſent baſſo relievos: the Greeks call pieces of this ſort μονοχρωματα.

CAMAIL, in *Ornithology,* ſynonymous with cravatte, according to Buffon, and other French writers, the black-faced tanager of Latham, and tanagra atra of Gmelin. This is a bird that inhabits Guiana, is about ſeven inches long, and of a cinereous colour, with the face, chin, and throat of the male black; and of the female, brown.

CAMAINES, Grand, in *Geography,* a large iſland, with low and ſmooth land, and trees on the top, about 46 or 48 leagues W.N.W. from the weſt point of Jamaica. The iſland is well ſtored with turtle.

Camaines, *Little,* are two iſlands, the weſternmoſt of which is called Camin Brack. They lie E.N.E. about 20 leagues from the Grand Camaines. The people of Jamaica catch many turtles here.

CAMALA, or Gamala, in *Ancient Geography,* a town of Spain, 24 miles from Lacobriga. Anton. Itin.

Camala, in *Geography,* a river that lies on the E. coaſt of Africa, within the long reef or ſand bank from Cape Corientes to the Barras Vermulas, an extent of at leaſt 400 miles.

CAMALDULIANS, Camaldunians, or Camaldolites, in *Eccleſiaſtical Hiſtory,* an order of religious, founded by Romuald, an Italian fanatic, in 1023, in the horrible deſart of Camaldoli, otherwiſe called Campo-Malduli, ſituate in the ſtate of Florence, on the Appenines.

Their rule is that of St. Benedict; and their houſes, by the ſtatutes, are never to be leſs than five leagues from cities. The Camaldulians have not borne that title from the beginning of their order; till the cloſe of the eleventh century they were called *Romualdins,* from the name of their founder. Till that time *Camaldulian* was a particular name for thoſe of the deſart Camaldoli; and D. Grandi obſerves, was not given to the whole order, in regard it was in this monaſtery that the order commenced, but becauſe the regulation was beſt maintained here.

Guido Grandi, mathematician of the great duke of Tuſcany, and a monk of this order, has publiſhed *Camaldulian* Diſſertations on the origin and eſtabliſhment of it.

The Camaldolites were diſtinguiſhed into two claſſes, of which the one were Coenobites, and the other Eremites.

CAMALODUNUM, Camudolanum, or Camulodunum, in *Ancient Geography,* a town of Albion, belonging to the Trinonantes, or Trinovantes. This town is placed by ſome of our antiquaries, as Talbot, Stillingfleet, and Baxter, at Colcheſter; but by Camden, Horſley, and others, more conformably to the itinerary of Antonine, and with greater probability, at Malden. Dr. Gale earneſtly contends for Walden. This was the capital of the powerful Britiſh king Cunobeline, and the firſt Roman colony in the iſland. Soon after the conqueſt of this part of the country by the Romans, a colony, conſiſting chiefly of the veterans of the 14th legion, was planted at Camudolanum by the emperor Claudius, A.D. 52; and by their wealth and induſtry, it became a place of great magnificence. But its proſperity was of no long duration; for it was quite deſtroyed by the Britons in their great revolt, A. D. 61. The theatre, the temple of Claudius, and the ſeveral villas in the neighbourhood, belonging to the Roman commanders, were ſo totally demoliſhed by the incenſed Britons, who beheld the colony as a ſeat of ſlavery, that our learned antiquarians have been much divided about the place where it was ſituated.

CAMAMU, Rio, in *Geography,* a large river of the Brazils, about 25 leagues to the ſouthward of Bahia; on the banks of which are ſeveral ſmall towns and villages, which are the beſt inhabited of any part of the Brazils. There are not leſs than 3 or 400 ſmall veſſels employed by the inhabitants to convey their commodities to Bahia and Rio de Janeiro. The Jeſuits formerly carried on a great traffic with this place, and ſent a large frigate loaded from theſe parts to Paraguay. The ſource of this river is in the centre of the gold mines.

CAMANA, or Camane, in *Ancient Geography,* a town of India, on this ſide of the Ganges, in the gulf of Barigazeni; ſuppoſed by ſome to be ſituate in the place of the preſent Cambay.

Camana, in *Geography,* a town of South America, and capital of the juriſdiction of Camana in the dioceſe of Arequipa, in Peru, ſituate on a river of the ſame name, near the South Pacific ocean. The juriſdiction is large, and contains many deſarts, eſpecially along the coaſt. Eaſtward it extends to the borders of the Cordilleras, ſo that the temperature of ſome parts is nearly the ſame with that of Arequipa, while others are cold; and both produce ſimilar grain and fruits. Its principal trade conſiſts in aſſes. It has ſilver mines near the mountains; but they are not worked. The town is 70 miles from Arequipa.

CAMANAR, a town that lies behind a ridge of rocks on the S. ſide of Gallipoli, on the Aſiatic ſhore of the paſſage towards Conſtantinople and the Black ſea.

CAMANBAYA, in *Botany* (Margraave and Petiver.) See Tillandsia *uſneoides.*

CAMANTIUM, in *Ancient Geography,* the name of a town of Aſia Minor, being, according to Athenæus, one of the ſeven towns which Cyrus conferred on his friend Clearchus.

CAMANUSALI, or Alcana Musali, in *Biography,* a phyſician and ſurgeon in much eſtimation, who practiſed at Bagdad about the middle of the 13th century. He wrote a treatiſe on the diſeaſes of the eyes, in which he profeſſes to have given all that could be found in the beſt Arabian, Hebrew, and Chaldean writers on the ſubject; particularly he deſcribes the method of curing cataracts by the uſe of ſetons. His work was tranſlated from the Arabic into Latin, and publiſhed at Venice in folio with the Chirurgi de Gui de Canliac, who frequently cites him. The title of the tract is "De Paſſionibus Oculorum Liber." It has been ſeveral times reprinted. Haller. Bib. Chir.

CAMARA, in *Botany* (Plumier, Dillenius, La Marck, Boſc.) See Lantana.

Camara, in *Ancient Geography,* a town of the iſland of

Crete, ſituate in the N. E. part of the iſland. Steph. Byz. and Ptolemy.—Alſo, a trading town of India, on this ſide of the Ganges. Arrian.

CAMARACUM, now *Cambray*, in *Ancient Geography*, a town of Belgic Gaul, thought by ſome to be the capital of the Nervii; but M. d'Anville thought this capital to have been *Bagacum*. The two moſt ancient works which mention this city are the Itinerary of Antonine and the Theodoſian table, whence it may be inferred, that if it exiſted before their time, it muſt have been an inconſiderable place.

CAMARADE, a companion, aſſociate, or friend. It is a term in uſe among ſoldiers to ſignify a perſon that is in the ſame tent, room, or chamber with them. It is alſo a name given to a battery which fires at the ſame time with another or more batteries, at one and the ſame ſpot. Thus, for inſtance, in battering one of the curtains of a work, three batteries are opened againſt it ſometimes at once, one of them a little advanced, or in the front, as it were, and another on each ſide of it called *camarade*.

CAMARAN, or Kamaran, in *Geography*, an iſland in the Red Sea, about 30 miles in length, and 20 in breadth, diſtant about 8 miles from the coaſt of Arabia. The principal employment of the inhabitants is fiſhing, eſpecially for pearls and coral. This iſland is diſtinguiſhed by a white houſe, or fortreſs, on the weſt end of it, where excellent water may be procured, but no proviſions, or merely ſuch as are very bad. N. lat. 15° 39′, E, long. 42° 22′.

CAMARASA, a town of Spain, in Catalonia, on the river Segro, about 9 leagues above Balaguer.

CAMARATA, in *Ancient Geography*, a town of Africa, in Mauritania Cæſarienſis, between Portus Sigenſis and Flumen Salſum. Anton. Itin.

CAMARES, in *Geography*, a town of France, in the department of Aveyron, and chief place of a canton in the diſtrict of St. Afrique; the place contains 1638, and the canton 8128 inhabitants; the territory comprehends $327\frac{1}{2}$ kiliometres and 14 communes.

CAMARET, a town of France, in the department of Finiſterre, ſituate in a bay to which it gives name; 8 miles S. of Breſt.

CAMARGUE, an iſland, or cluſter of iſlands, in the mouth of the Rhone in France, ſeparated by canals and fortified; the whole extent contains about 27 ſquare leagues, and is divided into eight pariſhes; the land is very fertile, but the air inſalubrious.

CAMARICA, a town of Spain, placed by Ptolemy in Cantabria.

CAMARINA, was formerly one of the moſt wealthy cities in Sicily. It ſtood between the rivers Oanus and Hipparis, now the Fraſcolari and Camarana, near the coaſt. Nothing now remains of this city but ſome ruins, and the name of Camarina, which is given by the natives to a tower and a neighbouring marſh. Camarina was founded in the 45th olympiad, deſtroyed by the Syracuſans in the 57th, and rebuilt between the 82d and 85th olympiad. After many revolutions, it was brought under ſubjection by the Romans, in the firſt Punic war.

An old tradition reports, that Camarina was built of the clay or mud which the river Hipparis carried along with it and depoſited in a lake of the ſame name. A paſſage in Pindar (Olymp. v. 29.) ſeems to confirm this account, which Ariſtarchus quotes in explaining it; and according to Bochart (Chanaan, i. 29. p. 605.), ſome proof is afforded by the name Camarina, as "Chamar," or "Chomar," ſignifies ſealing-clay. However, the old commentators on Pindar have not adopted this explanation. Didymus (ſee Oxford edition of Pindar, 1697, fol. p. 53, &c.), and others aſſert, that the poet alludes to the wood for building the city being conveyed in floats on the river Hipparis.

The *Palus Camarina* was a marſh or lake, ſituate near the city, which in time of drought yielded a ſtench that produced a peſtilence; and therefore the inhabitants conſulted an oracle, whether they ſhould not drain it. Although the oracle diſſuaded them, they drained it, and opened a way for their enemies to come and plunder their city. Hence aroſe the proverb "Ne moveas Camarinam," not to remove one evil in order to bring on a greater. This lake is now called "Lago di Camarana;" it is of a triangular form, and ſituate under the walls of Camarina.

Camarina, in *Geography*, a town of Spain in Arragon; 4 miles S. of Teruel.

CAMARINAS, a town of Spain, near the ſea-coaſt of Galicia; 25 miles W.N.W of Galicia.

CAMARINES, the moſt ſouthern province of the iſland of Luçon, one of the Philippines, in which are Bondo, Paſſacao, Ibalon, the metropolis of the government of Catanduanes, Bulan, Serſocon, or Bagatao, where the king's ſhips are built, and Albai, a large bay without the ſtrait, in which there is a high burning mountain, ſeen at a great diſtance by the ſhips coming from New Spain, and poſſeſſing ſome ſprings of hot water. Beyond Albai, towards the eaſt, is the cape of Buyſaygay; and coaſting from hence weſtward, we arrive at the river Bicor, which flows from a lake and runs by the city Caceres, the capital of the province. See Caceres.

CAMARINUM, or Camerinum, now Camerino, in *Ancient Geography*, a town of Italy in Umbria, on the confines of Picenum, and at ſome diſtance eaſt of Nuceria. It was probably powerful, as the Romans, A. U. C. 144, ſolicited an alliance with it; they afterwards eſtabliſhed a colony there. See Camerino. Strabo and Ptolemy.

CAMARIOCA, in *Geography*, a town of the iſland of Cuba; 15 miles E. of Havanna.

CAMARIPUGUACU, in *Ichthyology*, the name under which Marcgraave, and various other old writers, deſcribe the Braſilian ſpecies of Clupea, called by Brouſſonet and Gmelin Cyprinoides: ſee that article.

CAMARITÆ, in *Ancient Geography*, a people who inhabited the coaſt of the Caſpian ſea, on the iſthmus which ſeparates that ſea from the Euxine. Dionyſius Periegetes ſays, that they formed a numerous nation; and that they hoſpitably entertained Bacchus in his return from the Indian war.

CAMAROCENSIUM Civitas. See Camaracum.

CAMARON, or Cameron, *Cape*, in *Geography*, a headland of North America, in the gulf of Honduras. N. lat. 15° 35′. W. long. 83° 29′.

CAMARONES, a town of the iſland of Cuba; 75 miles S.E. of Havanna.

Camarones, or Jamour, a river of Africa, which riſes in the country of Biafra, and paſſing through the territory of the Calbongos, diſcharges itſelf into the Atlantic in the gulf of Guinea. N. lat. 3° 28′. E. long. 11° 30′.

Camarones, *Cape*, is a headland at the mouth of this river.

Camarones, a river of South America, forming a bay in the Atlantic, about 30 leagues N. from Port Deſire, or Deſeado, and 20 from cape Blanco, which lies between them. S. lat. about 44° 30′. W. long. 66° 20′.

Camarones, a river of South America, on the coaſt of Peru, which runs into the Pacific ocean, about 36 miles S. of Arica. S. lat. about 19° 20′. It is 8 leagues N. from Piſagua river. There is a point or cape of the ſame name, rendered white by the dung of the cormorants, that reſort to it in vaſt numbers. The iſland adjoining to it is ſometimes called Camaron, though its proper name is Guano.

CAMAROSIS, from καμαροω, *I arch over*, in *Architecture*, denotes an elevation with an arch or vault.

Camarosis, among *Phyſicians*, denotes a fracture of a bone, wherein the two broken ends riſe and form a kind of *camera*, or arch.

This is alſo called *camaroma*, and by modern Latin writers *cameratio*, ſometimes *fornicatio*.—It is commonly reſtrained to fractures in the ſkull.

CAMARRA, in *Geography*, a river on the N. coaſt of South America, W. from the river Maya. The intervening ſpace along the ſhore is covered with trees.

CAMARSEN, a town of Germany, in the Tyroleſe; 30 miles W. of Bolzano.

CAMASSEI, Andrea, in *Biography*, a painter of hiſtory and landſcape, was born at Bevagna, acquired the principles of deſign and colouring from Domenichino, afterwards ſtudied in the ſchool of Andrea Sacchi, and became eminent in his profeſſion. He was employed at St. Peter's at Rome, and at St. John Lateran; and his works were much admired for ſweetneſs of colouring, elegance of deſign, and delicacy of pencil. He died in 1648, as Sandrart ſays, in the bloom of life, and at a period when his reputation was daily advancing. His "Battle of Conſtantine and Maxentius," and "Triumph of Conſtantine" at St. John Lateran, are noble and grand compoſitions, evincing his powers of invention and correctneſs of execution. The picture of "Venus with the Graces," in the collection of the earl of Pembroke at Wilton, is aſcribed to Camaſſei. Pilkington.

CAMATULLICI, in *Ancient Geography*, a people of the Maritime Alps, on the ſea-coaſt S. W. of the Sueltri, placed by Pliny between Cithariſta and the Sueltri. Hardouin ſays, that they inhabited the dioceſe of Toulon.

CAMAX, in *Botany* (καμαξ, the prop of a vine, a ſtake, or pole). Schreb. gen. 365. Willden. 416. Ropourea, Aub. Guian. tab. 78. Juſſ. 421. La Marck Illuſt. Pl. 121. Claſs and order, *pentandria monogynia*.

Gen. Ch. *Cal.* perianth one-leafed, five-parted; ſegments roundiſh. *Cor.* one-petalled, wheel-ſhaped; tube very ſhort; border five-parted; ſegments roundiſh, hairy above. *Stam.* filaments five, inſerted into the corolla between the ſegments, hairy; anthers double. *Piſt.* germ ſuperior, roundiſh, hairy; ſtyle capillary; ſtigmas three or four, acute. *Peric.* berry egg-ſhaped, hairy, four-celled. *Seeds* numerous, bedded in a viſcous pulp.

Eſſ. Ch. *Calyx* five-parted. *Corolla* wheel-ſhaped. *Stigmas* three or four. *Berry* four-celled, many-ſeeded.

Sp. C. *fraxinea*. Willd. (Ropourea guianenſis, Aub. guian. 1. p. 198. tab. 78. La Marck Illuſt. Pl. 121.) A ſhrub, from 12 to 15 feet high. *Stems* three or four inches thick, ſimple, round, jointed. *Leaves* in whorls at each joint, declining, unequally winged; leaflets alternate, numerous, ſeſſile, egg-ſhaped, acuminate, entire, green on both ſides, from eight to ten inches long, and about three broad; midrib ſtrong, throwing out on each ſide alternate, ſimple, curved nerves, the intervals between which are occupied by very fine, zig-zag veins; each of the leaflets is furniſhed at its baſe with a ſmall ſpine. *Flowers* ſmall, of a ruſſet colour, axillary, numerous, nearly ſeſſile; hairs of the corolla and of the germ red. *Berry* yellow, about the ſize of a hen's egg, full of a ſweet pulp, which is eaten by the Creoles and natives of the country; one of the cells is often abortive, and as the others increaſe diſappears. A native of Guiana, where its branches are uſed by the negroes for wattling their huts. The Creoles call it Bois gaulette, and the Couſſaris, one of the aborigine nations, Aroupourou.

CAMB, or Kamp, in *Geography*, a river of Auſtria, which riſes on the frontiers of Bohemia, and diſcharges itſelf into the Danube.

CAMBADAS, a town of Spain, in Galicia, near the ſea-coaſt; 4 leagues W. of Ponte-Vedra.

CAMBADENA, in *Ancient Geography*, a country of Aſia; not far from Media. One of its principal towns was Baptana, ſeated on a mountain, in which were a column and ſtatue of Semiramis.

CAMBAHEE, in *Geography*, a river of America, which runs into the ſea near St. Helena's ſound, on the coaſt of South Carolina.

CAMBALA, in *Ancient Geography*, a place of Aſia, in the Greater Armenia, and in the Hyſperitide country, according to Strabo, who ſays that it had mines of gold.

CAMBALIDUS Mons, a mountain of Aſia, which, according to Pliny, was a branch of mount Caucaſus.

CAMBALU, a name formerly given to Pekin, the preſent capital of China. In 1307, it was erected by pope Clement V. into an archbiſhopric, which he conferred upon John de Monte Corvino, an Italian friar, who had been employed for many years in propagating the goſpel in that country. Upon his death in 1330, pope John XXII. ſent Nicolas of Bantra to fill the vacant ſee, and charged him with letters to the emperor of the Tartars, who was, at that time, in poſſeſſion of the Chineſe dominions.

CAMBAMBA, in *Geography*, a high mountain of Africa, giving name to the adjacent diſtrict, in the kingdom of Angola, on which is a mine of excellent ſilver. The Portugueſe have been for a long time maſters of it, and have built a ſtrong fortreſs; which, on account of its vicinity to the river Coanza, carries on a great commerce of ſlaves.

CAMBANA. See Cambona.

CAMBAT, a province of Abyſſinia, diſmembered from it by the Gallas. It occupies that diſtrict of Africa in the ſouthern part of Abyſſinia, which lies in about N. lat. 8°, and E. long. from about 37° to 38°. It is ſeparated from Gingiro on the weſt and ſouth-weſt, by the river Zebee; on the north it has the kingdom of Hadea, and other provinces of Abyſſinia; on the eaſt and ſouth-eaſt it has Buzamo and Alaba, and on the ſouth Makouko. This country is frequently haraſſed by the Gallas; and it is ſaid to pay ſome acknowledgments to the emperor of Abyſſinia, which are only voluntary. But little certain is known concerning it. It is inhabited by a mixture of Chriſtians, Mahometans, and Pagans; and abounds in various fruits.

CAMBAY, a large and beautiful city of Hindooſtan, ſituate near the head of the gulf of the ſame name, upon the north bank of the river Canari, called by ſome the Myhie. The city is twice as large as Surat, but not nearly ſo populous: it is defended by a ſtrong wall, about five miles in circumference; the ſtreets are large, and have gates at their entrances, which are ſhut in the night, and there are 12 gates to the city beſides thoſe of the ſtreets: the houſes are built of ſtone, brick, or marble; and here are three bazars, or public markets, and four public ciſterns, which are capable of ſupplying the whole town with water in times of the greateſt drought. This city is the port of Amedabad, from which it is diſtant about 56 road miles. Its trade is carried on by Mooriſh, Armenian, and Arabian merchants, with Perſia, Mocha, Diu, Acheen, Coromandel, and other places; and it was formerly very great in ſpice, ivory, ſilk, cotton cloths, and other commodities. But its commerce has declined, and is chiefly transferred to Surat, on account of the incommodiouſneſs of the harbour, which is obſtructed with ſand and mud, ſo that in the higheſt tides it has not more than ſeven fathoms of water, and the gulf is ſull of rocks. Cambay appears to be the Camanes of Ptolemy; although the gulf, which is now denominated from Cambay, had then its name from Barygaza, or the modern Baroach. It is diſtant 281 miles N. from Bombay; 1273 by Nagpour, and 1253 by Mundlah and Ougein nearly W. from Calcutta; 663 about S.W. from Delhi; and 998 N.W. from Madras. N. lat. 22° 16′ 45″. E. long. 72° 32′ 45″.

CAMBAYES, in *Commerce*, cotton cloths made at Bengal, Madras, and ſome other places on the coaſt of Coromandel. They are proper for the trade of Marſeilles, whither the Engliſh at Madras ſend great numbers of them. Many are alſo imported into Holland.

CAMBAZA, in *Geography*, a town of Japan, in the province of Ietſingo.

CAMBE, La, a town of France, in the deparment of Calvados, and diſtrict of Bayeux; four leagues W.N.W. of Bayeux.

CAMBELLO, a town of the iſland of Ceram, and principal market for cloves.

CAMBER-*beam*, in *Building*, a piece of timber cut archwiſe, or with an obtuſe angle in the middle, commonly uſed in platforms; as church-leads, and on other occaſions, where long and ſtrong beams are required. A camber-beam is much ſtronger than another of the ſame ſize; ſince being laid with the hollow ſide downwards, as they uſually are, it repreſents a kind of arch.

CAMBERED-*deck*, in *Ship-building*. See Deck.

CAMBERG, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and Lower Electorate; 22 miles N. from Mentz, and 30 E. from Coblentz. It is ſituated in a prefecturate of the ſame name; and the circumjacent tract contains fine arable land, but principally yields a good culture of flax.

CAMBERNON, a town of France, in the department of the Chanael: one league N.E. from Coutances.

CAMBERT, in *Biography*, a French opera compoſer, previous to Lulli, has no place aſſigned him here as a great muſician; but on account of his being connected, in ſome ſmall degree, with the hiſtory of the opera at Paris, his name will frequently occur to our readers in peruſing accounts of the origin of the muſical drama in France. Cambert was the firſt who attempted to ſet an opera in the French language upon the Italian model, previous to the licence which he had obtained, being transferred to Lulli, who began his opera career by compoſing the muſic for the dances. It being generally known that our monarch, Charles II. was very fond of French muſic and the amuſements of Louis the fourteenth's court, Cambert, in loſing his privilege, came to London, and was appointed maſter of king Charles the ſecond's band. His opera of "Pomone," written by P. Perrin, ſeems to have been performed in 1672 at court, in its original language, as no record of it occurs in our dramatic writers; but, acording to Giles Jacob, his "Ariadne, or the Marriage of Bacchus," tranſlated into Engliſh, "was preſented by the academy of Muſic, at the theatre royal, in Covent-Garden, 1674, by the gentlemen of the Academy of Muſic." We know of no theatre royal in Covent-Garden at this time, nor do we meet with any mention of an Engliſh academy of muſic at this period. It is ſaid, in the "Hiſtoire de la Muſic," tom. i. that Cambert, who died in London in 1677, broke his heart on account of the bad ſucceſs of his operas in England.

CAMBETUM, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the territory of the Lubenians, in the Tarragonenſis.

CAMBING, *Boorong Cambing*, or *Booring-volar*, in *Ornithology*, the name by which Marſden, in his hiſtory of Sumatra, diſtinguiſhes the gigantic crane, *ardea dubia* of Gmelin, a bird of vaſt ſize that inhabits alſo India and Africa. It is ſpecifically known by being of a glaucous colour above, beneath dirty white, and having the tail ſomewhat triangular. This is the *bargill* or *argill* of Ives.

Cambing, or *Kambing*, in *Ichthyology*, one of the ſynonyms of *chaetodon teira*, according to Renard and others. See Teira.

CAMBINI, in *Biography*, an Italian inſtrumental compoſer, poſſeſſed of genius and fire. He is ſaid by M. la Borde to be chiefly known to Dilettanti. We ſuppoſe the violin to be his inſtrument, of which he ſeems to know the finger-board well, and to write with fancy and facility.

CAMBIO, an Italian word which ſignifies *exchange*; commonly uſed in Provence, and in ſome other countries, particularly Holland.

CAMBIST, a name given in France to thoſe who trade in notes and bills of exchange. The word cambiſt, though a term of antiquity, is even now a technical word, of ſome uſe among merchants, traders, and bankers. Some derive it from the Latin cambium, or rather cambio.

CAMBIUM, in *Vegetable Anatomy*, is a name that has been very happily beſtowed by Duhamel and other phyſiologiſts upon the ſubſtance which is produced for the growth or repair of the vegetable body. The chief ſeat of the cambium in the dycotyledons, or thoſe plants with two ſeminal leaves, is between the bark and the wood. In order to obſerve it, we ſhould ſelect, in the full ſeaſon of vegetation, a branch of ſome tree, in which the bark is known to be eaſily ſeparable from the wood, ſuch as the oſier, when upon detaching a portion of the bark, its inner ſurface, and that of the wood correſponding to it, will be found covered with a quantity of fluid which poſſeſſes more tenacity than the common lymph or ſap, and reſembles mucilage or fluid jelly.

The cambium is generally reputed to be either an extravaſation from the ſurface of the wood, or that of the bark, but it is not determined from which of theſe parts it is derived, or whether they are not equally competent to produce it. Mirbel ſuppoſes that the cambium is furniſhed by the wood, and with apparent foundation, ſince in the monocotyledons it is depoſited around the ligneous fibres.

Grew and Duhamel did not allow this ſubſtance to be an extravaſated juice, but believed that it poſſeſſed organization and diſtinct parts, although they were ſo ſoft as to evade all means of detection. Without deciding upon this opinion, we muſt admit that the cambium is not a ſimple fluid, but muſt have received ſome modification to fit it for the important changes it is deſigned to undergo. As the ſeaſon advances, this ſubſtance (when ſituated under the bark,) acquires ſolidity and viſible organization, and is ultimately converted into the new layers of wood and bark, which are annually depoſited upon dycotyledons. See Bark, Cortical Layers, Liber, and Wood.

The gradual diſappearance of the pith in many trees depends upon the formation of the cambium, or organizing ſubſtance within the medullary canal. This produces an internal liber, which is by degrees transformed into wood, in the ſame manner as the external liber gives origin to the external woody layers, except that in the former, the increaſe is outwards, while in the latter, it is towards the center. See Pith, and Medullary Canal.

As the mode of growth in plants with one ſeminal leaf differs ſo materially from that of the dycotyledons, the cambium in them likewiſe holds a different ſituation. Inſtead of being depoſited near the ſurface of the plant, it ſurrounds the ligneous fibres which occupy the interior, where it is converted into the cellular and tubular texture ; the latter forms at firſt a very porous wood which inſenſibly contracts, elongates, and is transformed into perfect wood, during which proceſs it ſeparates from the parenchyma, and leaves a lacuna which is ſoon filled with new cambium. See Monocotyledon Wood.

All new formed parts, ſuch as buds, ſeeds, &c. may be ſaid to exiſt at one period as cambium ; even the hardeſt ſtone fruit, when firſt obſerved, is a tender vegetable jelly, in which no fibres, cells, or any diſtinction of parts, can be diſcovered.

When wounds are inflicted upon plants, their reunion is accompliſhed by means of the cambium, and from its organization ariſe the nodes or ſwellings, which are the conſequence of engrafting trees. If any injury to a vegetable be accompanied by deſtruction of parts, the reparation is commenced by a depoſition of cambium, and continued by repeated effuſions of the ſame ſubſtance until the reproduction is complete. See Wounds and Diseases *of plants*, and Ingrafting.

The analogy between the vegetable cambium and the coagulable lymph of animals is ſo palpable, that it is hardly neceſſary to point it out. Theſe ſubſtances equally afford the matrix in which organic ſtructure is begun, and conſtitute the moſt eſſential and important materials in the animal and vegetable ſyſtems.

CAMBLET, or Chamblet, in *Commerce*, a ſtuff ſometimes of wool, ſometimes ſilk, and ſometimes hair, eſpecially that of goats, with wool or ſilk : in ſome, the warp is ſilk and wool twiſted together, and the woof hair.

The true or oriental camblet is made of the pure hair of a ſort of goat, frequent about Angora, and which makes the riches of that city, all the inhabitants whereof are employed in the manufacture and commerce of camblets. It is certain we find mention in middle age writers of ſtuffs made of camel's hair, under the denominations of *cameletum* and *camelinum*, whence probably the origin of the term ; but theſe are repreſented as ſtrangely coarſe, rough and prickly, and ſeem to have been chiefly uſed among the monks by way of mortification, as the hair-ſhirt of later times. Du Cange, Gloſſ. Lat.

We have no camblets made in Europe of the goats hair alone ; even at Bruſſels they find it neceſſary to add a mixture of woollen thread.

England, France, Holland, and Flanders, are the chief places of this manufacture. Bruſſels exceeds them all in the beauty and quality of its camblets ; thoſe of England have been reputed the ſecond.

Camblets, *figured*, are thoſe of one colour, whereon are ſtamped various figures, flowers, foliages, &c. by means of hot irons, which are a kind of moulds, paſſed together with the ſtuff under a preſs. Theſe are chiefly brought from Amiens and Flanders : the commerce of theſe was anciently much more conſiderable than at preſent.

Camblets, *water*, thoſe which, after weaving, receive certain preparation with water ; and are afterwards paſſed under a hot-preſs, which gives them a ſmoothneſs and luſtre.

Camblets, *waved*, are thoſe whereon waves are impreſſed, as on tabbies ; by means of a calendar, under which they are paſſed and repaſſed ſeveral times.

The manufacturers, &c. of camblets, are to take care they do not acquire any falſe and needleſs plaits ; it being almoſt impoſſible to get them out again. This is notorious, even to a proverb : we ſay, a perſon is like camblet, he has taken his plait.

CAMBNITES lapis, in *Mineralogy*, a name given by the *Writers of the Middle Ages* to a ſtone, of which they record virtues which appear to ſavour too much of imaginary ones, ſuch as the curing of the dropſy by being tied to the arm : it ſeems to have been only a cloudy and leſs valuable kind of brown cryſtal.

CAMBODUNUM, or Campodunum, in *Ancient Geography*, a town of Vindelicia, 57 miles from Auguſta Vindelicum, now Kempten, in Suabia. Anton. Itin.

Cambodunum, a Britiſh ſtation in the Itinerary between Calcaria or Tadcaſter, and Manucium or Mancheſter. Dr. Gale and Mr. Baxter place it at Almonbury, where ſome Roman antiquities have been found ; but Mr. Horſley thinks it more probable that it was near Gretland.

CAMBOGE, Cambodia, or Levek, in *Geography*, the capital of Camboja, ſituated on a river of the ſame name. It conſiſts of one ſtreet, and a temple. The beauty of this temple is much extolled. It is ſupported by wooden pillars, varniſhed with black ; the foliages and reliefs are gilded : the pavement is curious and valuable, and mats are laid over it to preſerve it. The prieſts who ſerve in it hold the firſt rank in the ſtate. At a ſmall diſtance from this capital are ſeen the ruins of an ancient city, built with ſtone, the architecture of which ſomewhat reſembles the European ; and the adjacent lands are marked with furrows of former cultivation. No tradition concerning this city ſubſiſts among the preſent poſſeſſors of the country. N. lat. 12° 40′. E. long. 104° 48′.

Camboge, Camboja, Mecon, or Maykaung, names given to a large river which traverſes the whole country of Camboja. It riſes far north, and in the former part of its courſe, bears the name of Mecon ; in its further progreſs it paſſes by the towns of Lan-tchang, Tiem, and Columpé ; at a ſmall diſtance north of the capital it divides into three branches, two of which unite between the city and the ſea, and form the river, which aſſumes the name of Camboge ; the other branch is denominated Oubequame. Both diſcharge themſelves into the ſea by ſeparate mouths ; the mouth of the Camboge being in N. lat. 10° 20′ ; and that of the other in about N. lat. 10°.

CAMBOGIA, in *Botany*. See Garcinia.

CAMBOJA, Cambodia, Camboya, or Camboge, in *Geography*, a country of Aſia, bounded on the north by Laos, on the eaſt by Cochin-china and Ciampa, on the weſt by Siam and its gulf, and on the ſouth by part of the ſaid gulf, and the Indian Ocean ; and eſtimated at about 135 leagues in length, and 50 in breadth. This country, like Siam, is encloſed by mountains on the eaſt and weſt ; and it is fertilized by a large river, called Mecon, near its ſource, and Cambodia or Camboge near its æſtuary, and by ſome, very abſurdly, the Japaneſe river. This river, it is ſaid, begins to inundate the country in June. Near its mouth it is full of low iſles and ſand-banks, which impede the navigation, and it has no port or town. Sir George Staunton (Embaſſy to China, vol. i. p. 320.) informs us, on the authority of a manuſcript account of a voyage to this country, made in 1778, that the point of Cambodia, as well as the whole coaſt from thence to the weſtern branch of the great Cambodia river, is covered with under-wood, and exceedingly low. The ſea is ſo ſhallow, that at the diſtance of five or ſix miles from the ſhore, the water was ſeldom deeper than four fathoms ; and no veſſel much larger than a boat could approach within a couple of miles. The air is ſo hot that the inhabitants are under the neceſſity of reſiding on the banks of the rivers and lakes, where they are tormented by muſkettoes. The ſoil is fertile, and produces abundance of corn, rice, excellent legumes, ſugar, indigo, opium, camphor, and various medicinal drugs. The moſt peculiar product is the Camboge gum, which yields a fine yellow tint. Ivory alſo, and ſilk, are very plentiful, and of little value. The gold of this country is ſaid to be very pure; and it furniſhes amethyſts, hyacinths, rubies, topazes, and other precious ſtones. Cattle, particularly of the cow-kind, are numerous and cheap. Elephants, lions, tygers, and almoſt all the animals of the deſarts of Africa, are found in Cambodia. It has ſeveral precious woods, among which are the ſandal and eagle-wood, and a particular tree, in the juice of which they dip their arrows; and it is ſaid, that though a wound from one of the arrows proves fatal, the juice itſelf may be drank without danger. The country, though fertile, is very thinly peopled, inſomuch, that the king is hardly able to aſſemble 30,000 men; and its trade is inconſiderable. The inhabitants are Japaneſe, Chineſe, and Malays, together with ſome Portugueſe, who live without prieſts, and have intermarried with the natives. The men are generally well made, of a dark yellow complexion, with long black hair; their dreſs is a long and looſe robe; but the dreſs of the women, who are handſome, but not very modeſt, is ſhorter and cloſer. Their religion is idolatry. They manufacture very fine cloth, and the needle-work of the females is much admired.

CAMBONA, a ſmall iſland in the Indian Sea, near the ſouth coaſt of the iſland of Celebes. S. lat. 5° 22′. E. long. 125° 45′.

CAMBONES, a town of France, in the department of the Tarn, 7 miles E. of Caſtres.

CAMBONUM, in *Ancient Geography*, a place of Gaul, to the left of the Rhine, in the route which paſſes from Dea Vocontionum (Die), and Lucus Auguſti towards Vapincum (Gap), in going by Mons Seleucus.

CAMBORI, in *Geography*, a town of Aſia, in the kingdom of Siam, on the frontiers of Pegu, ſeated on a ſmall river which runs into the gulf of Siam.

CAMBORICUM, or CAMBORITUM, in *Ancient Geography*, a Britiſh ſtation in the fifth route of Antonine's Itinerary from London to Lugovallium or Carliſle, between Icianos and Duroliponte. All our antiquaries, except Mr. Horſley, fix Camboricum near Cambridge, at a place called by Bede, Grantceſter, and derive its name from *Cam*, crooked, and *brit*, a ford. Thoſe antiquaries who place Camboricum at Cambridge, fix Duroliponte at Godmancheſter.

CAMBRA, in *Geography*, a ſmall town of Portugal, in Beira.

CAMBRASINES, in *Commerce*, fine linen made in Egypt, of which there is a conſiderable trade at Cairo, Alexandria, and Roſetta or Raſchit. They are called cambraſines, from their reſemblance to cambrics.

CAMBRAY, in *Geography*, anciently *Camaracum*, a city of France, and principal place of a diſtrict, in the department of the North, ſeated on the Scheldt, which divides it into the eaſtern and weſtern parts, and fills its ditches with water. Before the revolution, it was the capital of Cambreſis, in the Low Countries, and the ſee of an archbiſhop, eſtabliſhed in 1559. The archbiſhop ſtyled himſelf Prince of the Holy Roman Empire, and Count of Cambreſis, and he was alſo lord of the city. It is well fortified, being defended by a ſtrong citadel on the Scheldt, and a fort; and as the land is low on that ſide of the river, the adjacent parts may be laid under water by means of ſluices. This city is large and tolerably handſome; its ſtreets are ſpacious; the place or ſquare for arms is ſo extenſive as to be capable of receiving the whole garriſon in order of battle. It has two collegiate churches, excluſively of the cathedral, which is dedicated to the virgin Mary, and one of the fineſt in Europe. The ſteeple is high, and from the top of it, commands a view of the whole city. It contains ten pariſh churches, three abbies, two convents, two hoſpitals, and ſeveral religious houſes. Its principal manufactures are lace, ſoap, and leather; and particularly the fine linen, hence called *cambric*. The eaſtern diviſion contains 6,600, and the weſtern 7,200 inhabitants; the former canton contains 14,391, and the latter 14,443 inhabitants; the whole territory comprehends 147¼ kiliometres, and 31 communes. Cambray is an ancient city, and was formerly imperial. It has been, on a variety of occaſions, the ſubject of conteſt between the emperors, the kings of France, and the earls of Flanders. In 1544 it was taken by the emperor Charles V. It was afterwards given to John of Montluc, by Henry III. of France, but beſieged by the Spaniards in 1596, when the inhabitants compelled the governor to ſurrender. Ever ſince it continued under the dominion of the houſe of Auſtria till 1677, when it came into the poſſeſſion of France. In Auguſt 1793, this city was inveſted and ſummoned to ſurrender by the Auſtrian general De Boros; the French general Declay returned for anſwer, that he did not underſtand ſurrendering, but he knew how to fight. In April, 1794, the French were defeated at Cæſar's camp, in the neighbourhood, by the allied army under the command of the duke of York, with the loſs of 1200 men, and three pieces of cannon; and the next day they left 1200 men dead on the field of battle, with the loſs of their general, Chapüy, 350 officers and privates taken priſoners, and 22 pieces of cannon. N. lat. 50° 10′ 32″. E. long. 3° 13′ 41″.

The league of Cambray, in 1508, was the moſt ſingular event that occurs in the hiſtory of Europe. It was a confederacy, inſtigated by pope Julius II. and which gained the concurrence of the emperor Maximilian I., of Louis XII. of France, by the ſuggeſtion of cardinal d'Amboiſe, and of Ferdinand king of Spain, for the final overthrow of the republic of Venice. This league originated in reſentment, and was diametrically oppoſite to the true intereſt of every one of the contracting powers. The republic of Venice had before this time acquired great power; but whatever were the means by which it had become thus powerful, it was now the bulwark of Italy; it prevented the pope from drawing the emperor or the king of the Romans, as he was then called, into Lombardy, againſt the French; it moderated the views of king Louis, and hindered him from extending his conqueſts; it kept the pope from being reduced to a ſtate of dependency; and it preſerved to Ferdinand the catholic the kingdom of Naples. Although it might have been the intereſt of each of theſe potentates, ſeparately, to recover, if poſſible, what had been taken from them by the republic; yet, to oblige her to refund all her conqueſts was to reduce a power of which they were all afraid, and thus to open a ſource of perpetual wars among themſelves. However, the league was formed; conſiſting of a variety of articles, advantageous to the ſeveral contracting parties, and threatening deſtruction to Venice. The execution of it was attended with all the ſucceſs that could be expected; for the emperor and the king of France wreſted from the Venetians almoſt all the cities which they poſſeſſed in Lombardy; nor was the pope remiſs in ſeizing all that lay convenient for his purpoſe. The Venetians, indeed, thought themſelves ſo little able to withſtand this powerful and formidable alliance, that they abandoned all the territories on the continent, after having loſt the famous battle of Ghiera d'Adda, in which their whole infantry was cut to pieces. However, after many humiliations and diſaſters, they preſerved their capital; and having either brought over, or bought over, the pope, the reſt of the confederacy was disjointed. The meaſures of the French and Germans, who were bent upon her total ruin, were traverſed by the king of Aragon and the pope, who would by no means concur in the utter deſtruction of the only power which had hitherto hindered theſe nations from ſubduing all Italy. The republic ſoon recovered a great part of her former territories; though ſhe was obliged to ſurrender to the pope Ravenna; to Spain, the five towns which ſhe had till this time poſſeſſed in Calabria; and to the emperor, Trieſte and Friuli.

CAMBREMER, a town of France, in the department of the Calvados, and chief place of a canton, in the diſtrict of Pont-l'Eveque; 5 leagues E. of Caen. The place contains 1200, and the canton 10,118 inhabitants; the territory includes 195 kiliometres, and 36 communes.

CAMBRENSIS, GIRALDUS, in *Biography*, arch-deacon, and afterwards, biſhop of St. David's, was born about the middle of the 12th century, and died after the year 1210. See GIRALDUS.

The account which this ancient prelate has given, in his deſcription of Wales, concerning the marvellous power which the Cambro-Britons and the Northumbrians had, of ſinging in parts ſpontaneouſly, at a time when counterpoint was unknown in the reſt of the world, not only merits notice here, but ſome diſcuſſion. See CAMBRO-BRITISH and NATIONAL MUSIC. Many eccleſiaſtical hiſtorians tell us that the organ was firſt admitted into the church at Rome by pope Vitalian, 666, the ſame pontiff who two years after ſent ſingers into Kent, to finiſh the work which Auſtin, the firſt Roman miſſionary, had begun. In 680, according to Bede, John, the præcentor of St. Peter's in Rome, was ſent over by pope Agatho to inſtruct the monks of Weremouth in the manner of performing the ritual, who opened ſchools for teaching muſic in other places of the kingdom of Northumberland. This may reconcile to probability ſome part of the following account, which Giraldus Cambrenſis gives of the peculiar manner of ſinging that was practiſed by the Welch, and the inhabitants of the north of England, about the end of the twelfth century.

" The Britons," ſays he, " do not ſing in uniſon, like the inhabitants of other countries; but in many different parts. So that when a company of ſingers among the common people meet to ſing, as is uſual in this country, as many different parts are heard as there are performers, who all at length unite in conſonance, with organic ſweetneſs. ' In unam denique ſub B mollis dulcedine blandâ conſonantiam et organicam convenientia melodiam.' In the northern parts of Great Britain, beyond the Humber, on the borders of Yorkſhire, the inhabitants uſe the ſame kind of ſymphonious harmony; except that they only ſing in two parts, the one murmuring in the baſe, and the other warbling in the acute or treble. Nor do theſe two nations practiſe this kind of ſinging ſo much by art as habit, which has rendered it ſo natural to them, that neither in Wales, where they ſing in many parts, nor in the north of England, where they ſing in two parts, is a ſimple melody ever well ſung. And, what is ſtill more wonderful, their children, as ſoon as they attempt uſing their voices, ſing in the ſame manner. But as not all the Engliſh ſing in this manner, but thoſe only of the north, I believe they had this art at firſt, like their language, from the Danes and Norwegians, who uſed frequently to invade and to occupy, for a long time together, thoſe parts of the iſland."

This extraordinary paſſage requires a comment. And firſt, it may be neceſſary, before we reaſon upon the circumſtances it contains, to be certain of their authenticity. Giraldus Cambrenſis is indeed an author who has been often ſuppoſed inaccurate and fabulous. " Girald Cambrenſis deſerves no manner of regard or credit to be given him; and his Chronicle is the moſt partial repreſentation of the Iriſh hiſtory that ever was impoſed on any nation in the world. He has endeavoured to make the venerable antiquities of the iſland a mere fable; and given occaſion to the hiſtorians that come after him, to abuſe the world with the ſame fictitious relations." Keating, part i. p. 13. Dr. Nicholſon, Biſhop of Derry's, Iriſh Hiſtorical Library, 1ſt ed. Dublin, 1724. The glaring improbabilities in the above account, with the manifeſt ignorance of the ſubject in queſtion, by no means contribute to augment his credibility. For whoever is acquainted with the laws of counterpoint, or with the firſt difficulties attending the practice of ſinging in parts, can have no exalted idea of the harmony of an untaught crowd, *turba canentium*, or ſuppoſe it to be much better than the diſſonant pæans of a good-humoured mob; in which the parts would be as various as the pitch of voices of which their chorus was compoſed. But how all theſe united at laſt in the conſonance of organic melody, and the ſoft ſweetneſs of B mollis, will long remain an impenetrable ſecret. If by *melodia organica* he meant organized, or harmonized, melody, we may ſuppoſe that the Cambro-Britons, in the time of Giraldus Cambrenſis, had acquired ſome knowledge in diaphonics, or diſcant; which according to John of Saliſbury, an elder writer, was practiſed to great exceſs in the 12th century. With reſpect to what he aſſerts of the people in Northumberland ſinging in two parts, it is more reconcileable to probability, from the circumſtances juſt mentioned, of the cultivation of muſic in that part of the world under Roman maſters, who may probably have firſt brought over the art of diſcant, or double ſinging, which the newly invented organ had ſuggeſted, by the facility it afforded of ſounding two or more notes at a time; which art, when practiſed by voices, was thence called *organum, organizare*. But as to what Giraldus ſays of children naturally ſinging in this manner as ſoon as they were out of the cradle, the reader will afford it what degree of weight he pleaſes; for our own part, we muſt own that it is not yet admitted into our muſical creed.

CAMBRESIS, in *Geography*, a province of France in the Low Countries, before the revolution, bounded on the north and eaſt by Hainault, on the ſouth by Picardy, and on the weſt by Artois. The length is about 10 French leagues, and its breadth from 5 to 6, and in ſome parts from 2 to 3. It is fruitful and populous, and watered by the Scheldt, Seille, and Sambre. The principal towns are Cambray, the capital, Chateau-Cambreſis, Crevecœur, Valincourt, and Vaucilles. Its inhabitants are laborious and lively, and addicted to the arts. Its commerce conſiſts chiefly in grain, ſheep, wool, and linen. Its paſtures are excellent, particularly for horſes and ſheep.

CAMBRETONIUM, in *Ancient Geography*, a Britiſh ſtation in the 9th route of Antonine's Itinerary, 15 miles from Anſa or Witham in Eſſex. Mr. Camden and Dr. Gale fix this ſtation at Brentonham, on the river Breton; but Mr. Horſley thinks that the diſtance ſuits better with Stratford, near the confluence of the Breton and the Stowr.

CAMBRIA, a name given to the province of Wales before the time of Cæſar's invaſion, and retained by it till about the cloſe of the 6th century, when it took the appellation of Wales; and when the inhabitants, likewiſe, with their ancient ſituation, loſt the title of Britons, and became diſtinguiſhed by the name of Welſh. See WALES.

CAMBRIC, in *Commerce*, a ſpecies of linen made of flax, very fine and white; the name of which was originally derived from the city of Cambray, where they were firſt manufactured. They are now made at other places in France.

The manufacture of cambrics hath long ſince proved of extraordinary advantage to France. For many years it appeared that England did not in this article contribute leſs than 200,000l. per annum to the intereſt of France. This proved motive ſufficient to induce the parliament of Great Britain to enact many ſalutary laws to prevent this great loſs of our wealth. See 18 Geo. II. c. 36. and 21 Geo. II. c. 26. See alſo ſtat. 32 Geo. II. c. 32. and 4 Geo. III. c. 37. which regulates the cambric manufactory, not long ſince introduced into Winchelſea in Suſſex; but very ſoon aboliſhed. The cambrics now allowed in this country are chiefly manufactured in Scotland and Ireland. Any perſon convicted of wearing, ſelling (except for exportation), or making up for hire any cambric or French lawns, are liable to a penalty of 5l. by the two firſt ſtatutes cited as above. The above cited ſtatute, 4 Geo. III. c. 37. eſtabliſhes the corporation of the Engliſh linen company for making cambrics and lawns, and enacts, that, whenever there ſhall be a manufactory of this kind, the commiſſioners of exciſe ſhall appoint the ſupervifor, or other officer, to ſeal the ſame; for which purpoſe notice ſhall be given by the manufacturer, before the piece is taken out of the loom, under penalty of 5l. and forfeiture of every ſuch piece. This piece ſhall be marked and numbered, on pain of 10l.; and an officer marking any piece not made in England, or after it is taken out of the looms, ſhall forfeit 50l. and his office. Attempt to bribe an officer incurs a penalty of 50l., and the officer accepting it forfeits 100l. and incurs the puniſhment of the pillory. Cambrics and lawns, made in England, and found unſtamped, ſhall be forfeited, ſeized, and ſold; and any perſon expoſing ſuch to ſale, or having them in his cuſtody for that purpoſe, ſhall forfeit 200l.; which goods ſhall be exported, and not relanded. To counterfeit the ſeal, or import any foreign cambrics or lawns with a counterfeit mark, or expoſe the ſame to ſale, knowing the ſtamp to be counterfeited, is felony without benefit of clergy.

CAMBRIDGE, in *Geography*, is a large, and the principal town in a county of the ſame name in England. It is particularly noted in the annals of literature and ſcience, for its univerſity, which has been honoured with the reſidence of many perſons of eminent and highly illuſtrious character, and provided for them the means of inſtruction. Concerning the priority of origin, and eſtabliſhment, of this, and the ſiſter univerſity at Oxford, there has been much controverſy with partial antiquaries. The original foundation of this town and ſeminary is involved in fabulous obſcurity; and the ſtories that have been propagated by ſome of the monkiſh writers confute themſelves by their own abſurdity. Without repeating any of theſe fables, or tracing up the annals of Cambridge anterior to the Roman colonization of Britain, we will endeavour to elucidate its hiſtory briefly from that period. "The ſite of the Roman *Granta*," obſerves Dr. Stukeley, "is very traceable on the ſide of Cambridge towards the caſtle, on the north-weſt ſide of the river, of an irregular figure containing 30 acres, ſurrounded by a deep ditch, great part of which remains on the ſouth-weſt, and in the grounds behind Magdalen college." Roman bricks, coins, urns, and pateræ have been found near this ſpot, and in the vicinity. The villages of Cheſterton and Grantcheſter, in the neighbourhood of Cambridge, have been conſidered by ſome antiquaries as occupying the ſites of Roman ſtations or camps; and as preſerving evidences of that in their preſent appellations. Other memorials of the Romans have been found in the military ways, or roads which diverged from the ſtation of Granta.

During the Anglo-Saxon dynaſties, the annals of Cambridge record but few events, and thoſe are merely of battles, ſieges, and other military operations. The univerſity, or rather a kind of academical inſtitution, appears to have been firſt founded early in the ſeventh century, by Sigebert, king of Eaſt-Anglia. How long this endured we are not informed; but as Alfred complained that he could not find teachers when he had youth and leiſure to be inſtructed, we may fairly preſume that there were no public ſeminaries at that time. The merit of reſtoring, or probably of founding the real univerſity belonged to Edward the Elder, ſon of Alfred the Great, who appears from the chronicle of Hyde-abbey, to have erected "halls for the ſtudents, and chairs and ſeats for the doctors, at his own charge." He alſo appointed profeſſors, and adopted other neceſſary meaſures which ſeemed to ſecure the ſtability of the inſtitution. In the year 1010 the town was fired, and plundered by the maurading Danes, who committed repeated depredations in this part of the iſland. At the time of the domeſday ſurvey, in the reign of William the Conqueror, it contained 373 houſes, 27 of which were ſhortly afterwards removed to make room for the *caſtle* erected by the Conqueror; or rather, as Fuller obſerves, "re-edified." In this fortreſs he ſoon afterwards received the ſubmiſſion of the monks of Ely, whoſe reſiſtance to his power appears to have been the principal inducement for erecting it. In the reign of William Rufus, the town and county of Cambridge were ravaged with fire and ſword by Roger de Montgomery, in revenge for an affront given him by the king. The univerſity was therefore for ſome time abandoned, but Henry I. induced the wandering ſtudents to return, by inveſting the town with many valuable privileges. He exempted it from the power of the Sheriff in the year 1101, and made it a corporation on payment to the exchequer of 100 marks annually. Joſfrid, abbot of Croyland, ſent four monks to Cottenham near Cambridge, from which place they daily repaired, according to Peter Bleſenſis, to the univerſity town, "and having hired a public barn, made open profeſſion of their ſciences, and ſoon collected a great number of ſcholars." Theſe continued to increaſe, and the place progreſſively acquired celebrity till 1174, when nearly the whole of the town was conſumed by a fire "ſo mercileſs," ſays Fuller, "that it only ſtopt for want of fuel to feed its fury." Moſt of the churches, as well as the houſes, appear to have been conſtructed with wood at this period. Tournaments were frequently held at Cambridge in the 13th century, and the concourſe of people was ſo great, that the ſtudents were much inconvenienced both in board and lodging. To remove this impediment to learning, Henry the Third forbade any tournament to be kept within five miles of the town. In examining the local annals of Cambridge, we find that frequent diſputes and altercations, often ending in battles, aroſe between the townſmen, and thoſe perſons connected with the univerſity. In 1281, a particular inſtance of this kind occurred. The towns-people aſſembled at their hall, and having choſen John Grantceter, for their leader, compelled him to ſwear that he would execute whatever the bailiff and burgeſſes ſhould command. Proceeding to Corpus Chriſti college, they broke open the doors, and carried away all the charters, and other documents; they next went to the houſe of the chancellor, whom they compelled, as well as all other perſons of the univerſity, to renounce the privileges that had ever been granted to them, and alſo deliver up all the letters-patent then in their poſſeſſion. After this they broke open the univerſity cheſt, which was kept in St. Mary's church, and taking out all the records, burnt them in the market-place, together with the papers they had previouſly collected. Numerous other acts of violence were committed. At length Henry Spencer, biſhop of Norwich, coming here with ſome ſoldiers, ſuppreſſed theſe daring tumults, and puniſhed the principal leaders; the mayor was deprived of his office, and the liberties of the town were declared forfeited, and beſtowed on the vice-chancellor, in whom they remained till the reign of Henry the Eighth, when the corporation was reſtored, but ſeveral of its former privileges were retained by the univerſity.

An inſurrection breaking out in the eaſtern counties in the time of Richard the Second, he ſummoned a parliament here in 1383. In this aſſembly a ſtatute was made againſt *wanderers*, or ſtudents of either univerſity, who traverſed the country *begging alms* without licence, which at that time was a common practice. On the 2d of May 1534, the univerſity renounced the ſupremacy of the Pope, and the next year ſurrendered all its charters, ſtatutes, and papiſtical muniments into the hands of Lord Cromwell. Theſe records were, however, ſoon afterwards reſtored, and the univerſity reinſtated in the full exerciſe of its privileges. From the death of Henry the Eighth, till the acceſſion of Elizabeth, the univerſity and town were in continued commotion, and various acts of hoſtility were committed by the oppoſite parties. The latter monarch, however, reſtored peace to the univerſity, where ſhe reſided five days in the early part of her reign. Here ſhe was entertained with various dramatic exhibitions, beſides orations, diſputations, and other academical exerciſes. On leaving the town, the queen in an elegant Latin ſpeech recommended the members of the univerſity to make the reſult of their ſtudies public.

In 1630, Cambridge was viſited by a dreadful plague, which occaſioned the buſineſs of the univerſity to be ſuſpended, and all the ſtudents had leave to retire to their reſpective homes. Between three and four hundred perſons fell victims to this direful malady. The aſſizes were at this time removed to Royſton. During the unhappy warfare between Charles I. and his parliament, the perſons of the univerſity very early declared themſelves in favour of the king, and as a pledge of loyalty, ſent their plate to be converted into money for his uſe, a few days before the erection of his ſtandard at Nottingham. This meaſure provoked the Cromwellian parliament, whoſe forces laid the town under repeated contribution, and the officers and ſtudents of the univerſity were compelled to ſeek ſafety in flight. Soon after the reſtoration, tranquillity was again reſtored; and ſince that period, various uſeful and important plans to promote the proſperity of the town, and the advantages of learning, have been progreſſively eſtabliſhed. The caſtle and fortifications have gradually crumbled in the courſe of time, and the univerſity has continued to increaſe its literary reputation from that epoch.

The extent of Cambridge occupies a ſpace of ground which meaſures about one mile from north to ſouth, and half a mile from eaſt to weſt. The ſtreets are in general narrow and winding, and the houſes ill-built, and too much crowded together. The town was firſt paved in the reign of Henry VIII. who, in his 36th year, cauſed it to be enacted by Parliament, that all perſons who had any houſes, lands, &c. in Cambridge, bordering on the highways, ſhould pave them to the middle of the ſaid ways, "in length as their grounds do extend," and alſo keep them in repair, under the penalty of ſixpence for every ſquare yard. In 1787, an act was paſſed "for the better paving, cleanſing, and lighting the town, and widening the ſtreets, lanes, and other paſſages." Many improvements in each of theſe reſpects have ſince been effected. The population compared with the limited extent of the town is very great; for beſides the perſons reſiding in the colleges, the number of inhabitants returned under the late act was 9273; of houſes 1733. The trade carried on at Cambridge is not inconſiderable; beſides that which is either immediately or remotely connected with the univerſity. The corporation conſiſts of a mayor, high ſteward, recorder, twelve aldermen, twenty four common council-men, four bailiffs, a town clerk, and other officers. The mayor, on the day of his election, has the privilege of beſtowing the freedom on any one perſon he may think proper. The choice of repreſentatives in Parliament is veſted in the mayor, bailiffs and freemen not receiving alms: the voters are about 200.

The *Caſtle* of Cambridge, of which there are ſcarcely any remains, was raiſed ſoon after the conqueſt; for 27 houſes are ſaid in the Conqueror's ſurvey to have been levelled for the purpoſe of erecting it. On the ſite of this ancient fortreſs, a new, large county gaol was lately built, upon a novel plan. Near this is a large conical mount, the keep of the ancient Norman caſtle. This occupies the higheſt ground in the town, and its ſummit commands a very extenſive tract of flat country. In the market place is a conduit, which was erected, and the water brought to the town by Thomas Hobſon the celebrated carrier, in 1614. Near it are the ſhire hall, and the town hall, two large buildings.

PUBLIC BUILDINGS. Cambridge contains 14 pariſhes, 13 of which are provided with their reſpective churches. Two only of theſe are, however, entitled to public notice, the others being moſtly ſmall, incongruous, and very inelegant buildings. Among the moſt ancient ſtructures in the town, and certainly the moſt curious ſpecimen of architectural antiquity it poſſeſſes, is the *Round Church*, or church of the *Holy Sepulchre*. This is one of the very few imitations which now remain in England, of the church of the Holy Sepulchre at Jeruſalem. The original building was perfectly circular, having its roof ſupported by eight large columns, between which and the outward wall, is a circular aiſle. The entrance door-way has a ſemi-circular arch of three different mouldings, which ſpring from capitals and columns of that ſtyle of architecture uſually called Saxon. Indeed the whole ſtructure was originally of this ſtyle, but has been altered at later periods; and at the time of ſuch alterations, the architects appear to have adopted the then prevailing mode of building. Mr. Eſſex (in vol. vi. of the Archæologia) affirms that it was built by the knights templars, or by ſome perſons concerned in the croiſades, in the reign of Henry the Firſt, or between the time of the firſt and ſecond cruſade. It is certainly the oldeſt church of the kind in England, though the temple church in London, and the round church in Northampton, are conſtructed nearly ſimilar in their reſpective ground plans; though their arches, columns, and ornaments, are very diſſimilar.

The univerſity church, called *Great St. Mary's*, though a large ſpacious building, is not remarkable either for its beauty, or uniformity of architecture. It was built by contribution, and though begun in the year 1478, it was not completely finiſhed till 1608. In the years 1783 and 1784, about 1500*l.* were expended in "repairing and beautifying this church;" but the alterations not being directed by taſte, have neither beauty nor ſcience to recommend them to our approbation. The other churches of Cambridge are moſtly built with brick walls, which are plaſtered and whitewaſhed.

The moſt conſpicuous and moſt celebrated building of the univerſity is *King's College chapel*, which, for elegance and beauty of parts, for grandeur of effect, and ſcientific conſtruction, is juſtly admired by all artiſts, connoiſſeurs, and architects. The deſign of this ſtructure is at once bold, chaſte, and profound; and its exterior and interior effects are grand and impreſſive. It conſiſts of only one ſpace or aiſle, which meaſures 287 feet in length, by 44 feet in width, and 93 feet in height. This ſpacious apartment is ſurrounded with various attractive beauties; and the ſculptor, painter, glazier, and architect, ſeem to emulate each other in exciting admiration. The whole interior ſuperficies is covered with numerous ſculptured ornaments, among which the arms and cognizances of the houſes of York and Lancaſter are moſt prevalent. The roſe, portcullis, fleur de lis, with ſhields of arms, are ſtuck all over the walls. Theſe are carved in high alto-relievo, and are executed with great ſkill and taſte. Some of the ſupporters diſplay the hand of a firſt-rate ſtatuary, and though cut in ſtone, are equal in contour, expreſſion, and character, to almoſt any marble ſculpture. A wooden ſkreen ſeparates the ante-chapel from the choir. The latter has two rows of ſtalls of carved wood on each ſide, and on the pannels at the back part of the upper rows, are carved the arms of all the Engliſh kings from Henry the Fifth to James the Firſt. The whole chapel is lighted by 26 large windows, beſide ſome ſmaller ones, which communicate to different lateral chapels, or chantries. Theſe occupy the ſpaces between the buttreſſes, and are now appropriated to libraries, and to other purpoſes. All the upper windows, except that at the weſt end, are filled with painted glaſs, which, for the ſtyle of drawing, colouring, compoſition, expreſſion, &c. manifeſt great talents in the artiſts who executed it. The groining and conſtruction of the roof of this fabric are regarded with admiration and aſtoniſhment. In forming the arch, and diſpoſing the materials, the architect has diſplayed ſuch a profound knowledge of geometrical principles, as to confound almoſt every other artiſt who has ſince examined his workmanſhip. It is traditionally reported that Sir Chriſtopher Wren annually viſited this pile, to view the roof; and the ſame tradition has given currency to an abſurd remark, which that great architect is ſaid to have made. This roof was executed by John Waſtell, and Herry Semerick, who by an indenture ſtill extant agree "to make, and ſett up, at their own coſts and charges, a good, ſure, and ſufficient vawte, for the grete church there, to be workmanly wrought, made and ſett up after the beſt handlying and forme of good workmanſhip according to a plat thereof made and ſigned with the hands of the lords executors to the kyng of moſt famous memorye Herry the VII, &c." They alſo agree to provide ſtone, and every other requiſite for the ſaid work, to finiſh it in three years, and to receive 1200*l.* for their whole labour and materials.

This magnificent fabric was begun by king Henry VI. who left particular directions in his will, and bequeathed ample endowments for the completion of the chapel and the whole college buildings, &c. But the former was not completed till the reign of Henry VIII. and the latter have never been finiſhed. It appears that only a part of the walls at the eaſt end of the chapel and to a certain height on the north and ſouth ſides, were raiſed during the lifetime of the founder. The building was a little advanced by Richard III.; and Henry VII. made much greater progreſs in the work. It advanced with rapidity during the reign of Henry VIII. and the caſe or ſhell of the building was finiſhed in 1515. For further particulars relating to the hiſtory and character of this ſtructure, ſee Malden's Account of King's College Chapel, 8vo.

Near the north ſide of this chapel is the *Senate Houſe*, which was built by Gibbs the architect from a deſign by ſir James Burroughs, who was maſter of Caius College. It was begun in the year 1722, and coſt nearly 20,000*l.* in completing; about 11,000*l.* of which were contributed by individual benefactors. It is built entirely of Portland ſtone, and adorned with pilaſters, frieze, baluſtrades, &c. in the Corinthian ſtyle of architecture. In the middle, both of the ſouth and eaſt fronts, is a grand triangular pediment, ſupported by four fluted columns of the ſame order. The interior is occupied by one large room, where all the public buſineſs of the univerſity is tranſacted. It meaſures 101 feet long by 42 feet broad, and 32 feet high. Near this building is the *Public Library*, which conſiſts of four rooms on the upper floor; the ground floor, conſiſting of three ſides of a ſquare, being occupied by the *Schools*. The library contains many curious, valuable and intereſting objects; among which is an antique ſtatue of Ceres brought from the temple at Eleuſis, the Cippus from the tomb of Euclid, the Beza MS.; and numerous other rarities.

Moſt of the other public buildings being connected with the colleges and halls, we ſhall notice the moſt intereſting under their reſpective eſtabliſhments, and ſhall arrange theſe in the chronological order of their foundations. Previous to the erection of colleges, the ſtudents reſided in hoſtels, or inns, which were provided by the townſmen for their reception. All the charges of education and maintenance were paid by themſelves; though the ſcholaſtic degrees and government were, according to the report given of the ancient ſtatutes, nearly the ſame as at preſent. In the time of Richard II. the number of hoſtels at Cambridge amounted to 16. The extravagant terms of landlords' charges probably gave riſe to the colleges; as it is recorded that they were very extortionate in their demands.

Colleges, &c.—The univerſity buildings conſiſt of twelve colleges and four halls, which laſt poſſeſs the ſame privileges as the former. Each of theſe contains apartments for the ſtudents and fellows, a maſter's lodge, a chapel, a library, a hall, and a combination room. In the following table is recorded, in chronological order, the name and the time of founding each of theſe inſtitutions.

| | |
|---|---|
| 1. Peter Houſe College, founded - - | 1257 |
| 2. Clare Hall, - - - | 1326 |
| This being burnt, was rebuilt in - - | 1344 |
| Again completely rebuilt in - - | 1638 |
| 3. Pembroke Hall, - - - | 1343 |
| 4. Gonville and Caius College, built by E. Gonville, | 1348 |
| Enlarged by Dr. Caius, - - - | 1557 |
| 5. Corpus Chriſti, or Bene't College, - | 1344 |
| Augmented in revenues, &c. - - | 1356 |
| 6. Trinity Hall, - - - | 1350 |
| 7. King's College, - - - | 1441 |
| 8. Queen's College, - - - - | 1448 |
| 9. Catharine Hall, - - - | 1475 |
| 10. Jeſus College, - - - | 1495 |
| 11. Chriſt's College, - - - - | 1505 |
| 12. St. John's College, - - - | 1509 |
| 13. Magdalen College, - - - - | 1519 |
| 14. Trinity College, - - - | 1546 |
| 15. Emanuel College, - - - - | 1584 |
| 16. Sidney Suſſex College - - | 1598 |

In addition to theſe, a new college, upon a large and grand ſcale, is propoſed and intended to be erected in purſuance of the will of ſir George Downing. This gentleman,

man, in the year 1717, deviſed various eſtates, &c. in failure of certain iſſue, for this purpoſe. The validity of the will was diſputed by ſome of his relatives, but after many years' litigation was finally ſettled in 1800, and the maſter, profeſſors, and three of the fellows are already appointed: thirteen other fellows are to be choſen when the college is built. We ſhall proceed to notice a few particulars relating to each of the above-named foundations.

*St. Peter's College*, uſually called Peter-Houſe, originally conſiſted of two hoſtels, which were purchaſed by Hugh de Balſham, ſub-prior of Ely, who appropriated them, in 1257, to the uſe of ſtudents. In 1284 he completely endowed his foundation for the ſupport of a maſter, 14 fellows, 29 bible-clerks, and 8 poor ſcholars; the number to be increaſed or diminiſhed according to the fluctuation of the revenues. Numerous benefactions have ſince been given to this foundation, and the fellowſhips are accordingly increaſed. The chapel was erected by ſubſcription in the year 1632, and is neatly embelliſhed, but was deprived of many of its ornaments by the fanatics in the civil wars. The building ſurrounds two courts, which are ſeparated by a cloiſter and gallery, and the largeſt court has had its buildings caſed with ſtone within a few years.

*Clare Hall* was built on the ſite of the Univerſity Hall, which was a ſmall college, founded in the year 1326 by Dr. Richard Baden, then chancellor of the univerſity. About 16 years after its erection, it was conſumed by fire, but rebuilt on a much more extenſive ſcale in 1344, by Elizabeth de Burg, heireſs to the laſt earl of Clare. By this lady it obtained its preſent name, with endowment for a maſter, 10 fellows, and the ſame number of ſcholars. Richard III., Thomas Cecil, earl of Exeter, John Freeman, eſq., William Butler, eſq., and Samuel Blyth, eſq. all contributed in augmenting the revenues, which now maintain 17 fellows, and between 30 and 40 ſcholars. This is the moſt uniform in its buildings, and is the moſt pleaſantly ſituated of any college in the univerſity. It was rebuilt of ſtone in 1638, except its chapel, which was erected in 1703, from a deſign by ſir James Burroughs. This college ſtands near the north-weſt angle of King's College chapel.

*Pembroke Hall* was founded by Mary, counteſs of Pembroke, in 1343, and endowed in purſuance of a charter from Edward III. for a maſter and ſix fellows. Among the benefactors who have enlarged this eſtabliſhment, Henry VI. is the moſt conſiderable; who augmented it with the rich living of Soham in this county, and with ſome other rectories. In his charter it is termed "the moſt noble, renowned, precious college, which, among all others in the univerſity, was ever wonderfully reſplendent." The preſent number of fellowſhips is 16, and the ſcholarſhips about 70. The chapel was built from a deſign of ſir Chriſtopher Wren, by his uncle, biſhop Wren. Contained in a ſmall detached building of this college is a large and curious aſtronomical machine, or ſphere, which was given and partly made by Dr. Roger Long, author of a celebrated treatiſe on aſtronomy; in which work it is particularly deſcribed; and the Dr. at his death bequeathed the intereſt of 200*l.* bank annuities to keep "the inſtrument and place" in good repair. This, like many other uſeful bequeſts, is perverted to private emolument, and the object conſequently neglected. This college conſiſts of two courts, which are ſeparated by the hall, having the combination room at one end.

*Corpus Chriſti*, or *Bene't College*, differs in its origin from all others, in either of the univerſities; thoſe having been founded by the benevolence of one or two perſons, while this was eſtabliſhed by the union of two guilds, or religious ſocieties. The college was begun in 1344, and its buildings were rapidly advanced by the influence of Henry Plantagenet duke of Lancaſter, whom the brethren had choſen as their firſt *alderman*. By the munificence of ſir John Cambridge and his ſon, the revenues were conſiderably augmented and finally appropriated, in the year 1356, to the maintenance of a maſter, eight fellows, three bible-clerks, and ſix ſcholars. Since that period, the endowments have increaſed ſufficiently to ſupport twelve fellowſhips, and nearly ſixty ſcholarſhips. The name of Bene't, or Benedict college, aroſe from its proximity to the church dedicated to that ſaint. Matthew Parker, archbiſhop of Canterbury, was the greateſt benefactor to this college, having founded two fellowſhips and five ſcholarſhips, and beſtowed on it the valuable library of Stoke-clare college, Suffolk, beſides many other printed books and manuſcripts. This college conſiſts principally of buildings round a ſquare court.

*Gonville and Caius College*, commonly called Keys College, was originally founded in the year 1348, by Edmund Gonville, who left a large ſum of money with Dr. Bateman to finiſh and endow it. The doctor being then employed on his own college (Trinity) did not immediately proceed with this building, but afterwards had it erected near his own foundation. Thus the preſent building is poſterior to that of Trinity, but its foundation and endowment being anterior, it certainly claims precedence in chronological arrangement. After its completion, it was called Gonville Hall; but in 1557 it obtained the preſent title, and was conſiderably increaſed in revenues and buildings. This was effected by Dr. John Caius, phyſician to queen Mary, who built a new court, and three remarkable gates of various and eccentric architecture. That on the ſouth, communicating with the ſchools, is ſaid to be the firſt ſpecimen of regular or Roman architecture erected in this country. The gates are reſpectively inſcribed, "Humilitatis," the gate of Humility; "Virtutis," the gate of Virtue; "Io. Caius Poſuit Sapientiæ," John Caius built this in honour of Wiſdom; "Honoris," the gate of Honor. Since the deceaſe of Dr. Caius, the fellowſhips have increaſed to 29, and the ſcholarſhips to nearly 100. The principal court of this college has been partly rebuilt, and is caſed with ſtone.

*Trinity Hall* was one of thoſe original hoſtels wherein the ſtudents reſided at their own expence. It was purchaſed by Richard Crowder, prior of Ely, in the reign of Edward III.; and was converted into a college, in 1351, by Henry Bateman, biſhop of Norwich. The founder provided for a maſter, three fellows, and two ſcholars; but various ſubſequent benefactions have increaſed the fellowſhips to twelve, and the ſcholarſhips to fourteen. The whole of this hall is faced with ſtone, and the buildings have a neat and uniform appearance.

*King's College*, the glory and pride of the univerſity, owes its origin and foundation to king Henry VI. who, in 1441, dedicated it, and in 1443 fully endowed it for a provoſt, 70 fellows, or ſcholars, 3 chaplains, 6 clerks, 16 choriſters, and a muſic maſter, 16 officers of the foundation, 12 ſervitors for the ſenior fellows, and 6 poor ſcholars. The monarch, dying before the eſtabliſhment was completed, left particular directions and bequeſts in his will for the fulfilment of his magnificent and pious deſigns. Theſe, however, were never completed, and only a ſmall part of the intended buildings have been erected. Some peculiar privileges appertain to this college. (See Raworth's Univerſity Calendar, 12mo. 1801.) Edward IV. inſtead of forwarding the plans of his predeceſſor, deprived this college of many large eſtates, which, with aggravated injuſtice, he gave to ſome of the ſycophant Oxonians then about his court. Henry VII. being ſafely ſeated on the throne, directed his attention, towards the latter end of his reign, to this building, on which he expended 2000*l.* and preſented the college with 5000*l.* more for the purpoſe of finiſhing the chapel. Beſides the elegant chapel already noticed, this college conſiſts of a row of buildings to the ſouth, alſo a large ſquare of buildings to the north of the chapel, and the provoſt's reſidence, &c. to the eaſt. In the library of the chapel is a plan of the college, as intended to be built by Henry VI. and ſome additional buildings are now propoſed to be erected.

*Queen's College* was founded in the year 1448, and endowed with revenues to the amount of 200*l.* per annum for the ſupport of a principal and four fellows, by Margaret of Anjou, the intrepid conſort of Henry VI. Elizabeth Widville, or Grey, queen of Edward IV. though a profeſſed enemy to the founder, was prevailed on by Andrew Ducket the maſter, to complete this college, and eſtabliſh it for a maſter, 19 fellows, and 45 ſcholars. The lady Elizabeth has ſince been annually celebrated as the co-founder. The buildings ſurround two quadrangular courts, one of which has a cloiſter of about 330 feet encompaſſing it. The chapel is fitted up peculiarly neat.

*Catharine Hall* owes its foundation to Robert Woodlark, chancellor of the univerſity, who in the year 1474 endowed it for a maſter and three or more fellows. This number is now increaſed to five; and eight bye-fellowſhips with ten ſcholarſhips have ſince been added. The buildings occupy three ſides of a quadrangular court.

*Jeſus College* was erected on the ſite of an ancient Benedictine nunnery, and founded by John Alcock, biſhop of Ely, in 1496, for a maſter, ſix fellows, and ſix ſcholars. The endowments have been increaſed, and now provide for ſixteen fellows, and nearly fifty ſcholars. This college is ſituated at a ſhort diſtance from the town, and its chapel, from the ſize and character, appears to have been the ancient conventual church, which was dedicated to St. Rhadagund in 1160.

*Chriſt's College* was built on the ſite of an hoſtel, called God's-Houſe, and appears to have been firſt founded by Henry VI. and completely endowed, in 1506, by Margaret counteſs of Richmond and Derby. The perſons now maintained on this eſtabliſhment are a maſter, 15 fellows, and about 70 ſcholars. The ancient buildings of this college incloſe a ſmall quadrangular court, behind which is a more modern uniform building, erected by Inigo Jones.

*St. John's College* received its name from the diſſolved hoſpital of St. John's, on the ſite of which it was built, and founded in 1511, though not opened till 1516. This was originally endowed by Margaret counteſs of Richmond, for a maſter and thirty-one fellows; but ſubſequent benefactions have united to raiſe a revenue to ſupport ſixty-one fellows and one hundred and fourteen ſcholars. The buildings of this college are moſtly of brick, and ſurround three courts.

*Magdalen College* owes its origin to Edward Stafford duke of Buckingham, who erected part of the preſent fabric, and intended to have endowed, and named it from his own title, but being beheaded, this with his other property was confiſcated. In 1542 it was obtained from the king, and endowed by Thomas lord Audley, for a maſter and four fellows. The latter number has ſince been increaſed to ſeventeen, and ſeveral ſcholarſhips have alſo been added. This college is built of brick, and conſiſts of two courts. Its library is noted on account of containing the valuable books and MSS. of Samuel Pepys eſq. who was ſecretary to the Admiralty in the reigns of Charles II. and James II.

*Trinity College* contains the largeſt buildings, and poſſeſſes the moſt conſiderable endowments of any collegiate eſtabliſhment in this univerſity. Its buildings ſurround two very large quadrangular courts, and its entrance-gateway, chapel, and library are fine and intereſting objects of architecture. This college was founded by Henry VIII. in 1546, on the ſite of two other colleges and a hoſtel, and endowed for a maſter, ſixty fellows, ſixty-ſeven ſcholars, four conducts, three public profeſſors, thirteen poor ſcholars, twenty beadeſmen, and other officers with ſervants: the number on the eſtabliſhment, at preſent, amounts to upwards of four hundred. The inner-court is called Neville's-court, from the name of Dr. Thomas Neville, at whoſe expence it was chiefly built, in the year 1609. Its weſtern ſide is formed by the library, which is a magnificent and ſpacious building, 200 feet in length, by 40 in breadth, and 38 in height. Beneath the library is a ſpacious piazza, which opens to the river and the gardens. In the chapel is a fine ſtatue of ſir Iſaac Newton, executed by Roubiliac. This figure is conſidered one of the fineſt ſpecimens of Engliſh ſtatuary.

*Emanuel College* was founded by ſir Walter Mildmay, on the ſite of a Dominican convent, in 1584, and endowed for a maſter, three fellows, and four ſcholars. By additional donations the revenues now ſupport fifteen fellows, and nearly one hundred ſcholars and exhibitioniſts. The hall is ſaid to be the moſt elegant of any in the Univerſity.

*Sidney Suſſex College* derives its foundation from Frances Sidney, counteſs of Suſſex, who, by will, dated December 6th 1588, bequeathed 5000l. and ſome other property to found a college for a maſter, ten fellows, and twenty ſcholars. The firſt ſtone of this college was laid on the 20th of May 1596, and the building completed in little more than three years. The chapel and the library were rebuilt about twenty years ſince, and various other alterations made at the ſame time. The foundation provides for ſeven fellows, ten bye-fellows, twenty ſcholars, and twenty-four bye-ſcholars, beſides a mathematical lecturer, and ſeveral exhibitioners.

In each, and all of theſe colleges, are various portraits of founders, and eminent perſons who have received education, or been immediately connected with the reſpective foundations. Each, alſo, contains a library, and in ſome are various uſeful, curious, and valuable natural and artificial objects. Numerous manuſcripts, miſſals, &c. contribute to enrich, and dignify many of theſe libraries; but to particularize the whole, or even barely to mention the moſt conſiderable, or important, would compel us to extend this article beyond the bounds of propriety and conſiſtency. At the end we ſhall refer to ſuch works as contain more detailed information on theſe ſubjects. All the colleges of this Univerſity are accommodated with ſpacious and pleaſant gardens, having convenient walks, which are ſheltered and enriched with rows of noble trees. Moſt of them are ſituated on the banks of the river Cam, at the weſtern extremity of the town. It is juſtly remarked by ſtrangers who viſit Cambridge, that its colleges and public buildings are, in general, neither grand, elegant, nor in a good ſtyle of architecture; and that a national Univerſity ſhould diſplay and encourage the polite arts of the country. In the college now preparing to be built, it is hoped that the directors or Committee will ſelect ſuch deſigns as ſhall at once be a memento of their taſte, an honour to the Univerſity, and creditable to Engliſh talent.

*The Univerſity* is compoſed of a chancellor, vice-chancellor, the maſters or heads, fellows of colleges, and ſtudents, amounting in all to more than 2000 members; and is incorporated as a ſociety for the ſtudy of all the liberal arts and ſciences. Each college, or hall, is a body of itſelf, and bound by its own ſtatutes; but is likewiſe controuled by the paramount law of the Univerſity, each furniſhing members for the government of the whole; which government is adminiſtered by the following officers:—

1. *A Chancellor*, who is ſome nobleman, and may be changed every two years, or continued longer by the tacit conſent of the Univerſity.—2. *A High Steward*, choſen by the ſenate, and holding his office by patent from the Univerſity; he is allowed a deputy.—3. *A Vice-chancellor*, who is uſually the head of ſome college or hall, and choſen yearly on the 4th of November, out of two perſons nominated by the heads.—4. *Two Proctors*, choſen annually on the 10th of October, who muſt be maſters of arts; they attend to the diſcipline and behaviour of all under-maſters of arts; read the graces, and take the votes in the White-hood houſe. —5. *Two Taxors*, choſen as the proctors, and who with them are clerks of the markets, and have cognizance of weights and meaſures; they were originally intended to tax, or fix the rent of the houſes let to the ſcholars for their reſidence.—6. *Two Moderators*, who ſuperintend the exerciſes and diſputations in philoſophy, and the examinations previous to the degree of bachelor of arts.—7. *Two Scrutators*, whoſe office is to read the graces, and take votes of the Black-hood houſe, to which they always belong.—8. *A Commiſſary*, who is uſually appointed an aſſiſtant or aſſeſſor, and deputy high-ſteward to the vice-chancellor in his court, (much the ſame as a recorder is to a mayor, or a chancellor to a biſhop).—9. *A Public Orator*, who is the mouth of the Univerſity on public occaſions, writes their letters, preſents noblemen to their degrees with a ſpeech, &c.—10. *The Caput* conſiſts of the vice-chancellor, a doctor of divinity, a doctor of laws, a doctor of phyſic, a regent and non-regent maſter of arts, who are choſen yearly on the 12th of October, and are to conſider and determine what graces are proper to be brought before the body of the Univerſity; and each of them has a negative voice. All graces muſt firſt paſs the caput before they can be produced to the ſenate.—11. *Two Librarians.*—12. *A Regiſtrar.*—13. *Three Eſquire Bedells*, &c. There are alſo profeſſors in divinity, civil law, phyſic, caſuiſtry, hebrew, greek, arabic, mathematics, philoſophy, aſtronomy, anatomy, chemiſtry, botany, modern hiſtory, common law, foſſils, and muſic.

*The Senate* is compoſed of all the doctors and maſters of arts in the Univerſity, and is divided into two bodies or houſes. The firſt conſiſts of regents, or thoſe who have not been maſters of arts five years: they are alſo called white-hoods, from the hoods of their official dreſſes being lined with white ſilk. The ſecond, of non-regents, or thoſe who have taken the degree of maſter upwards of five years, but have not advanced to the degree of doctor; theſe are called black-hoods for a ſimilar reaſon. The doctors under two years ſtanding vote ſolely in the regent-houſe; but all others, with the public orator, may vote in which houſe they pleaſe; and either houſe is competent to reject a queſtion. In the ſenate-houſe the election of all officers takes place, the appointments of the magiſtrates, the admiſſion to degrees, and all other important buſineſs of the Univerſity. No language but Latin is permitted to be ſpoken at any official meeting in the ſenate-houſe. Some queſtions are determined by the body collective, as the choice of members of parliament. At the election in 1790, the number of members who voted was 684; abſent, or did not vote, 181; in all 865. The privilege of ſending members to parliament was firſt granted to the Univerſity by James I. in 1604. The whole number of fellows in the Univerſity is 406, and of ſcholars 666; beſides which there are 236 inferior officers and ſervants of various kinds, who are maintained on the foundation; theſe, however, are not all the ſtudents of the Univerſity. There are beſides two other orders, called penſioners, the greater, and the leſs: the greater penſioners are the young nobility and gentlemen of fortune, who are called fellow-commoners, becauſe they dine with the fellows; the leſs are dieted with the ſcholars; but both live at their own expence. There is alſo a conſiderable number of ſcholars of an inferior fortune, called ſizars: theſe, though not of the foundation, are capable of receiving many benefactions called exhibitions, which aſſiſt them greatly in paſſing through an expenſive education; and frequently, by merit, they ſucceed to the higheſt honours and emoluments. The ſtudents, according to their ſtanding and proficiency in learning, are entitled to the degrees of bachelor and maſter of arts, bachelor and doctor in divinity, phyſic, and law. The time required by the ſtatutes for ſtudying in the Univerſity, before each can be qualified for taking the ſaid degrees is three years for a bachelor, and about four years more for a maſter of arts; ſeven years after that he may commence bachelor of divinity, and then five years more are required to take the degree of doctor in divinity. In law, a ſtudent may commence bachelor after ſix years, and in phyſic after five years ſtanding: both may be proctors at the end of five years more. The proper time for conferring theſe degrees is called the commencement, which is always the firſt Tueſday in July, when the maſters of arts, and doctors of all faculties, complete their degrees reſpectively. The examination for the degree of bachelor of arts uſually begins on the Monday ſe'nnight after the Epiphany, and the degree is completed on the ſecond tripos-day next following. Perſons are commonly admitted to the degree of bachelors in divinity on the 11th of June. The nobility, which includes baronets, as ſuch, are entitled to degrees without waiting the ſtatutable time. In the year 1786, ſome diſputes having aroſe concerning the practice of conferring degrees in right of nobility, the ſtatutes were examined, and it was determined that the following perſons were entitled to honorary degrees: *viz.* 1. Privy-counſellors.—2. Biſhops.—3. Noblemen—Dukes, Marquiſſes, Earls, Viſcounts, Barons—4. Sons of Noblemen.—5. Perſons related to the king by conſanguinity or affinity, provided they be alſo honourable.—6. The eldeſt ſons of ſuch perſons.—7. Baronets.—8. Knights. The two laſt to the degree of M. A. only.

As a ſtimulus to that laudable emulation which ſhould ever be encouraged in the youthful mind, the Univerſity, and different individuals have left ſeveral ſums of money, &c. to be annually diſtributed among the ſcholars, as "the reward of merit."—The yearly donations thus beſtowed by the Univerſity amount to 353l. 5s. of which 50l. is given to ſuch as excel in mathematics, and 303l. 5s. for the encouragement of claſſical and Engliſh compoſitions. The annual prizes conferred by individual colleges amount to 286l. two-thirds of which are appropriated to promote claſſical literature.

Thus, by the liberality of different perſons, zealous for the honour and advantages of learning, has this Univerſity attained a high degree of eminence, and many of its members have been materially benefitted. The various incentives to excellence here held forth, and the numerous rewards of merit annually diſtributed are exquiſitely adapted to rouſe genius into energy, and impel ſluggiſhneſs to action, to give reſolution to timidity, and furniſh modeſty with hope. How animating muſt it be to the emulous mind, to reflect that, " it is placed under thoſe venerable walls, where a Hooker and a Hammond, a Bacon and a Newton, once purſued the ſame courſe of ſcience, and from whence they ſoared to the moſt elevated height of literary fame. This is that incitement which Tully, according to his own teſtimony, experienced at Athens, when he contemplated the porticoes where Socrates ſat, and the laurel grove where Plato diſputed." (Idler, N° 33.) N. lat. 52° 12′ 36″. E. long. 0° 4′ 15″.

" Majeſtic Granta, hail thy awful name,
Dear to the muſe, to liberty, to fame." MASON.

CAMBRIDGE, a townſhip in Grafton county, New Hampſhire, North America, E. of Androſcoggin, and S. of Umbagog lake.

Alſo, a townſhip of Waſhington county, New York, containing, by the cenſus of 1790, 4996 inhabitants, including 41 ſlaves; and by the cenſus of 1796, it appears, that it has 623 electors.—Alſo, the half-ſhire town of Middleſex county, Maſſachuſetts, which is one of the largeſt and moſt reſpectable townſhips of the county. Its three pariſhes, Cambridge, Little Cambridge, and Menotomy, contain three congregational meeting-houſes, one for Baptiſts, and another for Epiſcopalians, a number of pleaſant ſeats, and 2115 inhabitants. It is connected with Boſton by an elegant bridge. The public buildings are the meeting-houſes, court-houſe, and the edifices belonging to Harvard Univerſity, which are four in number, *viz.* Harvard, Hollis, Maſſachuſetts Halls, and Holden chapel. This Univerſity is, with regard to its library, philoſophical apparatus, cabinet of minerals, and profeſſorſhips, the firſt literary inſtitution on the American continent. It takes its date from the year 1638, ſeven years after the firſt ſettlement in the townſhip, then called Newtown. It has generally from 140 to 200 ſtudents. By a mean of the obſervations made in this place during the years 1781 and 1783, its temperature appears to be 50° 3, that is, about 10 degrees below the European ſtandard. N. lat. 42° 25′. W. long. 71° 10′.—Alſo, a poſt-town of Ninety-ſix diſtrict, in the upper country of South Carolina, where the circuit courts are held. It contains about 60 houſes, a court houſe, and a brick-gaol. The college by law inſtituted here, is no better than a grammar-ſchool: 80 miles N.N.W. of Columbia; 50 N. by W. of Auguſta in Georgia; 140 N.W. of Charleſtown, and 762 S.W. of Philadelphia. N. lat. 34° 9′.—Alſo, the chief town of Dorcheſter county, Maryland, ſituate on the ſouth ſide of Choptank river, about 13 miles E.S.E. from Cook's point at its mouth: nine W.S.W. from Newmarket; and 57 S.E. from Baltimore. Its ſituation is healthy, and it contains about 50 houſes, and a church. N. lat. 38° 34′. —Alſo, a town of Franklin county, Vermont, ſituate on both ſides of La Moille river, about 20 miles W. of Lake Champlain. It has 359 inhabitants.

CAMBRIDGE *Manuſcript*, or *Beza's MS.* a copy of the Goſpels, and Acts of the Apoſtles in Greek and Latin, noted by Wetſtein in the 1ſt and 3d parts of his Greek Teſtament by the letter D. In the Greek it is defective, from the beginning to Matth. i. 20; in the Latin, to Matth. i. 12; and it has likewiſe the following chaſms: Matth. vi. 20.— ix. 2. xxvii. 1—12. John, i. 16.—iii. 26. Acts, viii. 29.—x. 14. xxi. 2—10. xxii. 10—20. And from xxii. 29 to the end. Some pages of this MS. containing Matth. iii. 8—16. John, xviii. 13.—xx. 13. Mark, xvi. 15, to the end, are written by a later hand, which Wetſtein refers to the 10th century, but Grieſbach to the 12th. The Goſpels are arranged in the uſual order of the Latin MSS. Matthew, John, Luke, Mark. Dr. Kipling, in a preface to his edition of this MS., has comprized his obſervations upon it under four diſtinct heads, of which we ſhall avail ourſelves in the ſequel of this article. He begins, *firſt*, with eſtabliſhing its high *antiquity*. It is univerſally allowed, by the moſt competent judges, that this MS. is one of the moſt ancient. Thoſe who give it the leaſt antiquity aſſign it to the 6th or 7th century. Wetſtein and I. D. Michaelis deem it much older: and Dr. Kipling is of opinion, that it is more ancient than the Alexandrian MS. and muſt have been written in the ſecond century. His conjecture is founded on theſe circumſtances; that it wants the doxology at the end of the Lord's prayer, and has the Ammonian ſections, without the Euſebian canons. That the doxology is an interpolation, admits of little doubt; but it is not ſo clear how the want of it in a MS. furniſhes a proof of the high antiquity of that MS. If the writer of Beza's MS. were a Latiniſt, he might leave out the doxology in his Greek copy, becauſe it was not in his Latin copy; or his Greek copy might have been one of thoſe which wanted the doxology. Dr. Kipling's argument, derived from the entire omiſſion of the Euſebian canons, and from the Ammonian ſections being added by a poſterior writer, is more ſpecious. Hence he infers, that the text of the MS. was written antecedently to the date of the Ammonian ſections, and theſe before the Euſebian canons appeared. Ammonius lived in the third, Euſebius in the fourth century: the Ammonian ſections in Beza's MS. are much poſterior to the text, and are without the canons of Euſebius; therefore it is highly probable that thoſe ſections were added to the MS. before the fourth, and that the MS. itſelf was written before the third century. However, a MS. of the 5th, 6th, or 7th century might have been written, in uncial letters, without either the marginal ſections of Ammonius, or the canons of Euſebius; and the former might have been added without the latter ſome years after that period. This argument has been applied by Grabe, Caſley, and Woide to the Codex Alexandrinus (See ALEXANDRIAN *copy*), and by Hichtel to the Codex Vaticanus. It deſerves to be further illuſtrated and examined. In MSS. of the New Teſtament, the four Goſpels are divided into greater and ſmaller portions; the one called τιτλος, the other κεφαλαιον; in the ſame manner, though in different proportions, as we divide them into chapters and verſes. The τιτλοι, or larger portions, were generally marked in the upper margin; the κεφαλαια, or, as they are frequently called, the Ammonian ſections, were always marked at the ſide; and to theſe ſections Euſebius adapted his ten tables, or harmony of the Goſpels, to which he referred by writing, under each of the Greek letters or numbers expreſſive of the Ammonian ſections, letters which denoted that part of each table where the ſection was to be ſought. This is clearly exhibited either in Stephens's edition of 1550, or in Kuſter's edition of Mill's Greek Teſtament. The Acts of the Apoſtles, and the Epiſtles, were likewiſe divided into ſections, called, from the inventor, the ſections of Euthalius; and they were noted in the margin by letters, in the ſame manner as the Ammonian ſections in the Goſpels. As the Euthalian ſections are not marked in the margin of the Acts of the Apoſtles, and the Epiſtles, in the Alexandrian copy, though the τιτλοι and κεφαλαια are noted in the Goſpels, Grabe, Caſley, and Woide, contend, that the Alexandrian copy was written before Euthalius had introduced theſe ſections, that is, before the year 396. Mr. Marſh, however, (ubi infrà) obſerves, that a conſiderable time might have elapſed after the year 396, before theſe ſections were brought into general uſe. Beſides, though no ſections are marked in the margin of the Alexandrian copy, in the Acts, and the Epiſtles, yet the text itſelf is very diſtinctly divided into ſections, by blank ſpaces at the end of each ſection, and by large letters written in the margin, at the beginning of each ſection. The diviſions into ſmaller portions was probably later than the diviſion into larger portions; and the portions into which the Acts of the Apoſtles are divided in the Alexandrian copy, appear to be nothing more than a ſubdiviſion of the Euthalian ſections. Upon the whole, ſays Mr. Marſh, the writer of the Codex Alex. ſeems to have been unacquainted with the Euthalian diviſion, and Woide's argument is indeciſive. In applying the ſame argument to Beza's MS. the ſame objection will occur. For though no ſections are noted in the margin, yet the text itſelf is divided into ſections, not by blank ſpaces, as in the Alexandrian copy, but by the firſt word of each ſection being ſo written, that the firſt letter ſtands in the margin, which is ſometimes greater, but in general of the ſame ſize with the other letters. It appears, on an examination of Beza's MS., that whenever an Euthalian ſection commences in the Alexandrian MS. a new ſection begins in Beza's MS., and that the ſections of theſe two MSS. in the Acts of the Apoſtles, are only different ſubdiviſions of the Euthalian ſections. This argument, therefore, inſtead of being favourable to theſe MSS., rather proves, that neither of them was written before the fifth century.

Moreover, the τιτλοι of Euſebius are wholly unnoticed in the margin of Beza's MS.; and the κεφαλαια, or Ammonian ſections, are not accompanied with the references to the canons of Euſebius. This is obſerved by Mill, in his "Prolegomena," who aſcribes the omiſſion of theſe references to forgetfulneſs; but this, ſays Mr. Marſh, cannot have been the reaſon, becauſe the ſections are ſometimes written ſo cloſe together, as to leave no room for a reference between them. This ingenious writer expreſſes his ſurpriſe that Mill did not deduce this very obvious inference from the omiſſion of theſe references to the canons of Euſebius, viz. that Beza's MS. was written, not indeed before the time of Euſebius, but before the tables which he invented were brought into general uſe; and as Euſebius was a man of ſo diſtinguiſhed a character, and we know that Jerom himſelf adopted theſe canons, we might ſuppoſe, that they were generally adopted within 100 years after their invention. But the true reaſon why Mill did not apply this argument, was his having ſeen ſeveral other MSS. of the goſpels beſides Beza's copy, which have the Ammonian ſections without the references to the canons of Euſebius. Their abſence, therefore, from the Codex Bezæ affords no abſolute proof of its antiquity. Beſides, the Ammonian ſections in Beza's MS. are noted in the margin by a different, and, of courſe, later hand, than that which wrote the MS. itſelf. This is aſſerted by Mill, Wetſtein, and Grieſbach, who have all examined the MS. Although the Ammonian ſections are noted in the margin with the ſame uncial letters as are uſed in the text, and the ink is in both places of the ſame tawny colour; yet the letters in the margin are ſomewhat ſmaller than thoſe in the text, and ſome of the former, when cloſely examined, manifeſtly differ from thoſe in the latter. Inſtances to this purpoſe are produced by Mr. Marſh. It is certain alſo, he adds, that the writer of the Codex Bezæ did not intend that the text ſhould be divided into the Ammonian ſections; for he has actually divided it into ſections of a totally different kind. They are denoted by the firſt word of each ſection projecting into the margin; ſo that the firſt letter ſtands out of the text, but is contiguous to the ſecond letter, and is generally of the ſame ſize with the reſt, though it is ſometimes larger. A further proof that the writer of the Codex Bezæ did not intend to mark the Ammonian ſections is, that an Ammonian ſection frequently begins in the middle of the line; whereas thoſe above mentioned commence always at the beginning of the line. And though the perſon who added the Ammonian ſections has conſtantly added two dots (:) before the word which begins the ſection, yet the interval is frequently ſo ſmall between it and the preceding word, that he was obliged to add them nearly at the top of the letter. What argument then can be deduced from the above-mentioned omiſſion, in reſpect to the antiquity of Beza's MS.? If we conclude that it was written before the invention of the Ammonian ſections, we ſhall refer it to the beginning of the third, or the end of the ſecond century; againſt which it may be objected, that the concluſion would be too haſty, becauſe a conſiderable time might have elapſed before their uſe was become general. But as theſe diviſions were adopted and recommended by Euſebius in the fourth century, and likewiſe by Jerom at the end of the ſame, and beginning of the following century, they muſt have been univerſally known before the cloſe of the fifth; and though it may be ſaid that the writer of the Codex Bezæ muſt have copied from ſome more ancient MS., and might therefore tranſcribe the old, long after the new diviſions were introduced, we may reply, ſays Mr. Marſh, that as the Codex Bezæ is written in a ſplendid and expenſive manner, it is probable, that the perſon or perſons for whom it was written, would have choſen that ſuch chapters or ſections ſhould be obſerved in it, as were in general uſe at the time when it was written. If we argue, therefore, from the omiſſion of the Ammonian ſections, we may fairly conclude, that the Codex Bezæ is at leaſt as ancient as the fifth century. But as the writer of this MS. has adopted ſections in the Acts of the Apoſtles, which imply the previous exiſtence of the Euthalian ſections, we would not, ſays Mr. Marſh, aſcribe to it a greater antiquity. If we argue, ſays this judicious critic, from the internal evidence of the text, and conclude from the antiquity of its readings, that is, from the circumſtance that the Codex Bezæ is free from many ſpurious additions and alterations, that were introduced into the more modern Greek MSS.; the inference deducible is, not that the MS. itſelf is ancient, but only that it has a very ancient text, which is a matter of much greater importance than the antiquity of the vellum and the ink. It is certain that it was written before the eighth century, from the ſhape of the letters, the want of intervals between the words, and alſo of accents and marks of aſpiration; for in the eighth century, the Greek uncial letters degenerated from the ſquare and round form, which is ſeen in the Codex Bezæ, into an oblong ſhape; marks of aſpiration, and accents were added, and the elegance of writing conſiderably decreaſed. It appears alſo from comparing the letters of the Codex Bezæ with the Greek inſcriptions given by Montfaucon, (Pal. Græc. p. 158—175.) not only that it *muſt* be more ancient than the eighth century, but that it *may* be as ancient as the ſixth, the fifth, or even the fourth century. No inſcription reſembles it ſo exactly, as to the ſhape of its characters, as that given by Montfaucon, which was engraved about the middle of the ſixth century, in the reign of Juſtinian. But this is no argument againſt its higher antiquity. Upon the whole, from comparing the Codex Bezæ with Greek inſcriptions of different ages, we may conclude that it cannot have been written later than the ſixth century, and that it may have been written even two or three centuries earlier. The tawny colour of the ink diſcovers, indeed, the higheſt antiquity: but no great ſtreſs can be laid on this circumſtance, becauſe, if two MSS. were written with the ſame ink, the one in the fourth, the other in the ſixth century, they would probably be faded at preſent in a nearly equal degree; and the difference between 12 and 14 hundred years would hardly be ſufficient to enable us to diſcover at preſent any difference in the colour; not to add, that as ſome inks are more durable than others, the letters of a modern MS. may be more faded than thoſe of a more ancient MS. With reſpect to the comparative antiquity of the Codex Bezæ with that of other MSS., it may be ſafely aſſerted, that no one can be put in competition with it, except the Codex Vaticanus. The moſt ancient Greek MSS., meaning thoſe only which are quoted by Wetſtein, beſides theſe two, have, according to him, the uſual τιτλοι and κεφαλαια. We may therefore ſuppoſe, that thoſe which have more ancient diviſions, and have other marks denoting the greateſt antiquity, are in this reſpect entitled to the higheſt rank. If it is aſked to which of theſe the precedence is due, Mr. Marſh replies, to the Codex Bezæ; for the Codex Vaticanus has accents and marks of aſpiration which were added by the perſon who wrote the MS. itſelf.

The *ſecond* object to which Dr. Kipling directs his attention is the *nature* and *excellence* of Beza's MS. Antony Arnauld maintains, that it is a forgery of the 6th century, and therefore, unworthy of credit; and his chief argument for this unfounded opinion is, that it has additions or interpolations, which are not found in the copies anterior to that period: but this aſſumption is not juſt, for it is very far from being certain that the ſame and ſimilar interpolations were not found in any other MS. before the 6th century. Dr. Kipling, on the other hand, alleges, by a method of reaſoning not very ſatisfactory, that the additions above mentioned are proofs that either the MS. of Beza, or its archetype, muſt have been written before Jerom corrected the text of the New Teſtament, becauſe they are not in his verſion. Bengelius ſuppoſes this MS. to be of Britiſh manufacture, from its very great conformity with the Anglo-Saxon verſion; and that it was reformed, or rather depraved, by means of the Italic verſion. To which it is replied, that the MS. of Beza reſembles the Syriac verſion as much as it does the Italic and Anglo-Saxon; and, therefore, it may as juſtly be called a Syriacizing MS. as a Latinizing one. In this connection we may obſerve, that according to the opinion of Wetſtein, in which he was generally followed, till Semler queſtioned it, the Codex Bezæ contained a Greek text which was altered from the Latin; or, in other words, that the writer of the Codex Bezæ departed from the readings of the Greek MS. or MSS. from which he copied, and introduced in their ſtead, from ſome Latin verſions, readings which were warranted by the authority of no Greek MS. Allowing as a fact, that a great number of the readings peculiar to the Codex Bezæ are found in the Vulgate, and that they are found in no Greek MS. at preſent known, and that with regard to moſt of the readings, in which the Codex Bezæ differs from all the Greek MSS., it agrees with ſome one of the Latin verſions publiſhed by Blanchini; ſhall we hence conclude, that theſe readings were actually borrowed from a Latin verſion, and tranſlated into Greek? It is at leaſt as poſſible, ſays Mr. Marſh, that they might have had their origin in the Greek, as in the Latin: and this poſſibility is ſufficient to defeat the whole of Wetſtein's hypotheſis. Beſides, it is highly probable, as well as poſſible, that this might be the caſe. It is merely more reaſonable to ſuppoſe, that a tranſlation would be altered from an original, than an original from a tranſlation: and this ſuppoſition is confirmed by fact, for when Jerom reviſed the Latin verſion by order of pope Damaſus, he corrected it from Greek MSS. Beſides, the Codex Bezæ has additions, omiſſions, and tranſpoſitions, which are found neither in the Vulgate nor any other Latin verſion now extant. Since, therefore, the Latin verſions of that MS. agree with the Greek text, even in places where it is ſupported by no Latin MS. at preſent known, we muſt conclude, that the Latin was adapted to the Greek, and not the Greek to the Latin. That the Codex Bezæ ſhould agree, either with the Vulgate, or ſome other Latin verſion, is not extraordinary, when we reflect, that this MS. is one of the oldeſt now extant, and that the Greek MSS., from which the Latin verſions were made, come nearer to it, in point of time, than to thoſe Greek MSS. from which the Codex Bezæ differs. To this muſt be added, that a great number of theſe readings are found in the Syriac, the Coptic, the Sahidic, the margin of the Philoxenian verſion, the Verſio Syra-Hieroſolymitana, and the quotations of Origen. And we muſt ſuppoſe that all theſe have been corrupted from the Latin; if the charge be true, with reſpect to the Codex Bezæ. There is no reaſon whatever for aſcribing any reading of a Greek MS. to the influence of the Latin, unleſs it can be proved, that it could not have taken its riſe in the Greek, and that it might eaſily have originated in the Latin. But no inſtance of this kind has been produced from the Codex Bezæ. Michaelis mentions two inſtances out of many more which might be produced, which ſeem to reſcue the copyiſt from the charge of having corrupted the Greek from the Latin. 1. The Greek text varies ſometimes even from the Latin verſion, with which it is accompanied. 2. The Latin text appears, in ſome caſes, to have been altered from the Greek. We ſhall only add, under this head, that as the Codex Cantabrigienſis was probably written in Europe, as appears from its being accompanied with a Latin tranſlation, it ſeems improbable that the Syriac verſion ſhould be uſed in the correction of a MS. written in a country where the Syriac language was wholly unknown; and the only ſuppoſition that can make the conjecture probable is, that the Greek text of the Cod. Cant. was taken from a Greek MS. written in Aſia. But this conjecture is altogether unneceſſary. Upon the whole, the Biblical critic may probably not demur in ſubſcribing to the judgment of Mill or Semler, as to the utility of this and other ſimilar Græco-Latin MSS.; that they are valuable monuments of antiquity, and exhibit many important readings, to be found in no pure Greek copies, but which are moſtly inſerted in the old Italic verſion, and in the works of the Latin fathers.

As to the Latin verſion, annexed to the Greek of Beza's MS., it is evidently the old Italic, before it was corrected by Jerom. It is, in general, an exact counterpart of the original, from which it rarely deviates. The intention of the writer, whoever he was, ſeems to have been to make his Latin copy tally with the Greek. That he adapted his Latin verſion to his Greek text is clear from many paſſages that might be adduced. On the other hand, the writer of Beza's MS. ſometimes, though not ſo frequently, adapted his Greek text to ſome Latin copy. In John, v. 2. the Greek has Βελζεθα inſtead of Βηθεσδα, which reading, it is probable, was never found in any pure Greek copy of St. John: but it is the Latin reading of Corby's MS. as well as of Beza's; to which the former bears throughout a ſtrong reſemblance. Dr. Kipling imagines, for reaſons which he alleges, that the Latin verſion in Beza's MS. is not all written by the ſame hand.

The *third* object of Dr. Kipling's reſearch is the *peregrinations* of the Cambridge MS., which he traces from Egypt to Cambridge. We ſhall, with Michaelis, invert the order of this route, becauſe our knowledge of it in later times is certain; whereas the higher we aſcend, the greater is the obſcurity in which we are involved, till at length we loſe ourſelves in the maze of thoſe unwarranted conjectures that have been hazarded by Wetſtein. It is a 4to ſize, and written on vellum; 66 leaves of it are much torn and mutilated, ten of which are ſupplied by a later tranſcriber. In 1581, the Univerſity of Cambridge received this MS. as a preſent from Theodore Beza, who then reſided at Geneva. It had been in his poſſeſſion about 19 years; and was found, according to his account, in the monaſtery of St. Irenæus at Lyons, in the year 1562; from which period he made uſe of it till the year 1581, and has frequently quoted it in his edition of the Greek Teſtament, publiſhed in 1582. Beza wrote, in the beginning of this MS., the following account with his own hand. "Eſt hoc exemplar venerandæ vetuſtatis ex Græciâ, ut apparet ex barbaris quibuſdam Græcis ad marginem notatis, olim exportatum, et in S. Irenæi monaſterio Lugdunenſi, ita, ut hic cernitur, mutilatum, poſtquam ibi in pulvere diù jacuiſſet, repertum, oriente ibi civili bello, Anno Domini 1562." He gives the ſame account in his letter to the Univerſity of Cambridge, dated Genevæ, Id. Decemb. 1581; and alſo in the page preceding the preface to his edition of the Greek Teſtament, printed in 1582.

That the MS. came originally from Greece is conjecture; but that it was diſcovered in the monaſtery of St. Irenæus, at Lyons, depends upon the direct and poſitive evidence of a man, whoſe veracity we have no reaſon to doubt. Wetſtein aſſerts, and it has been ſtrenuouſly maintained by others, that the Cod. Cantab. and the Codex β. Stephani, which, as he relates, ſome of his friends had collated in Italy, for his edition of the New Teſtament, in 1550, are one and the ſame MS. Beza, however, quotes them as totally diſtinct; but in the opinion of Michaelis very obvious circumſtances decide in favour of Wetſtein. Mr. Marſh, without deciding on the queſtion, impartially ſtates the arguments on both ſides, and leaves the determination to the reader. In favour of the opinion, that they are one and the ſame MS. Wetſtein alleges, 1. That the Lectiones ſingulares, amounting to 450, quoted in Stephens's Margin from the Codex β. agree exactly with thoſe of the Codex *Bezæ*, except in ſome few inſtances, which appear to be typographical errors. 2. That where the Codex Bezæ has chaſms, no readings are quoted in Stephens's Margin from the Codex β; though, if we except theſe chaſms, the Codex β is quoted by Stephens in every page. 3. That ſeveral remarkable additions to the common text, found only in the text of the Codex Bezæ, are quoted by Stephens from his Codex β. Againſt theſe arguments the following objections may be urged: 1. The Lectiones ſingulares, quoted from the Codex β. do not amount to 450, but only to 211. 2. To the ſecond argument it may be replied, that the premiſes are not perfectly true, for the Codex β. is actually quoted by Stephens in four inſtances, where the Codex Bezæ has a chaſm. In favour of the opinion, that the Codex Bezæ and the Codex β. are two diſtinct MSS. may be alleged the following arguments: 1. It appears from the direct and poſitive evidence of Beza, given clearly and conſiſtently at three different times, that his MS. of the Goſpels and Acts was diſcovered in the monaſtery of St. Irenæus, at Lyons, in 1562, and that from the intelligence he could procure, it had lain there time immemorial. If this account be true, the Codex Bezæ could not poſſibly have been collated in Italy by Henry Stephens fifteen years prior to that period, and the MS., which Stephens collated muſt now lie buried in ſome Italian library. 2. Henry Stephens, who collated the Codex β. lived in habits of intimacy with Beza, and printed ſome of his editions of the Greek Teſtament; and muſt unavoidably have been led by the ſame curioſity, which induced him to examine every Greek MS. which he could procure, to inſpect, at leaſt, the two celebrated MSS., which Beza uſed in his edition of 1582, and in which H. Stephens himſelf wrote the "Exhortatio ad Lectorem." If, therefore, Beza's MS. of the Goſpels and Acts had been the very ſame which he himſelf had collated a few years before, he muſt have recognized ſo remarkable a MS., and of courſe would have mentioned it to Beza. But Stephens has no where given a hint of its being the ſame, though he had a fair opportunity of doing it, where he ſpeaks of the MS. which he himſelf had collated, *viz.* in the preface to the edition of the Greek Teſtament of 1587, printed three years after Beza's third edition; and Beza conſtantly quotes it as a different MS. from the Codex Stephani β. 3. In four inſtances, where the Codex Bezæ is defective, Stephens quotes readings from his Codex β. 4. The author of the "Specimen Animadverſionum in Prolegomena Wetſtenii," has produced twenty readings, in which the Codex Bezæ and the Codex β. contradict each other. 5. Though the characteriſtic readings of the Codex β are found in general in the Codex Bezæ, yet, on the other hand, there are ſome very long and remarkable readings in the Cod. Bezæ, which Stephens has not quoted from his Codex β. To theſe arguments for the diverſity of the MSS. it may objected, 1. That Beza's poſitive evidence can go no further than to the place where, and the time when, the MS. was found, not to the number of years, during which the MS. had been preſerved there. 2. That though H. Stephens, who collated the Codex β, and muſt frequently have ſeen the Codex Bezæ, has no where aſſerted that they were one and the ſame MS., yet the argument drawn from his ſilence is only negative, and that arguments of this kind are not always concluſive. But it is more difficult to find an anſwer to the other part of this argument, *viz.* that Beza had conſtantly quoted the two MSS. as diſtinct; which he hardly would have done, if Henry Stephens had ever obſerved that they were one and the ſame. Wetſtein, however, who takes for granted, that H. Stephens actually informed Beza that they were one and the ſame MS. goes ſo far as to accuſe Beza of a wilful intention to deceive. 3. That the four quotations from the Codex β, in the two places where the Codex Bezæ has a chaſm, may be explained, either on the ſuppoſition, that two leaves, which are now wanting, have been loſt ſince Stephens's time, or as typographical errors. 4. That the argument drawn from the contradictions referred to is inconcluſive, becauſe many inſtances may be produced of collations made by different perſons from the very ſame MS. which contradict each other much more frequently than the extracts from the Codex β. contradict the readings of the Codex Bezæ. 5. That the fifth argument is not abſolutely deciſive, ſince it is poſſible that H. Stephens might overlook the moſt remarkable readings, even in places where we ſhould leaſt expect it; and likewiſe poſſible, if he had noted them, that the ſame remarkable readings might have been overlooked both by R. Stephens and Beza. Michaelis, who adopts the common hypotheſis, that the Codex Bezæ and the Codex Stephani β. are one and the ſame MS., is reduced to the neceſſity of ſuppoſing, that the MS. which Henry Stephens collated in Italy, not long before the year 1550, was afterwards depoſited in the monaſtery of St. Irenæus, and there diſcovered in 1562: though Beza declares expreſsly, that it had lain there time immemorial. Dr. Semler conjectures, that the Codex Stephani β. might have been a tranſcript of the Cod. Cant. and brought to Italy a ſhort time before it was collated. Wetſtein conjectures, that the Codex Bezæ was either preſerved during ſome time at Trent, or that Henry Stephens, after having collated it in Italy, delivered it to the biſhop of Clermont, at the time when the celebrated council was held there, in 1546, and that the biſhop brought it from the council to his dioceſe of Clermont in Auvergne. Theſe two parts of Wetſtein's hypotheſis directly contradict each-other; for it appears, from Mattaire Hiſt. Stephanorum, that H. Stephens did not go to Italy till after the death of Francis I. which happened in 1547. He could not, therefore, deliver it to the biſhop of Clermont, at Trent, in 1546; and if the biſhop was in poſſeſſion of the Codex Bezæ, and brought it home with him, which we muſt ſuppoſe, if it was diſcovered at Clermont in Auvergne, in 1562, it cannot poſſibly have been the MS. which H. Stephens collated in Italy, between the years 1547 and 1550. Wetſtein ſuppoſes, that Beza's MS. was found in France about the year of Chriſt 840, and that it is the ſame copy which Druthmar, an ancient expoſitor, who lived at that period, had ſeen, and which, he obſerves, was aſcribed to St. Hilary. In this MS. the Latin arrangement of the Goſpels was obſerved; but this of itſelf is not ſufficient to prove its identity with Beza's, as 600 years ago there were other Greek MSS. beſides the Cod. Cant. in which this order was followed. Beſides, Semler has juſtly obſerved, that this MS. is Latin as well as Greek; and moreover it contains the Acts of the Apoſtles, which Druthmar has not related of his MS. Wetſtein pretends to have diſcovered the Cod. Cant. among thoſe which were collated at Alexandria, in 616, for the New Syriac Verſion, becauſe he found a coincidence in ſeveral readings: but it is highly improbable, that a Latin tranſlation would be added to Egyptian MSS. of the New Teſtament.

As to the place where this MS. was originally written, Simon, Mill, Wetſtein, Michaelis, and moſt other critics, contend that it was written in the weſt of Europe, where Latin was better underſtood than Greek, ſince a tranſlation would have been wholly ſuperfluous, if the MS. had been written when the original language of the Greek Teſtament was the language of the country. Some have ſuppoſed without ſufficient reaſon, that it was written by a Latin ſcribe; but this ſuppoſition is needleſs, becauſe it is highly probable, that in Italy or ſome other part of the weſt of Europe, where Latin was ſpoken, and where this MS. was written, Greek ſcribes were employed for copying Greek books. This opinion is ſupported not only by Simon, Mill, Wetſtein, Michaelis, &c. but it is likewiſe defended by Montfaucon, of whom Mr. Marſh ſays, he is one of the beſt judges of antiquity that ever exiſted. There is no preſumption whatever, a priori, ſays the ingenious writer juſt mentioned, againſt the opinion, that the Codex Bezæ was written in the weſt of Europe; and it is conſidered highly probable by the two following circumſtances: 1. The Latin tranſlation was added with no other view, than as a means of making the original intelligible to thoſe who were not ſkilled in the Greek; and it was not added merely in conſequence of the high authority of the church which uſed it. For in that caſe the tranſcriber would have adopted ſome eſtabliſhed text, from which he would never have deviated; whereas the Latin text of the Codex Bezæ is found in no Latin MS. either ancient or modern. It has omiſſions, inverſions, and interpolations, agreeing with the Greek text to which it is added, but differing from all other MSS. whether Greek or Latin. This tranſlation would have been altogether ſuperfluous, if the MS. had been written for the uſe of a Greek, and ſtill more ſo, if written in Egypt, as Father Georgi ſuppoſes, where Latin was unknown. 2. The goſpels, in the Codex Bezæ, as we have already obſerved, are written in the following order, Matthew, John, Luke, Mark; which arrangement was never admitted by the Greek church, or in any country ſubject to its authority; but it was the common arrangement of the ancient Latin MSS. as appears from the Evangelarium Quadruplex, of Blanchini. From all theſe circumſtances it ſeems reaſonable to conclude, that the Codex Bezæ was written in the weſt of Europe, in a country where the Latin was better underſtood than Greek, and which was ſubject to the authority of the church of Rome. A MS written in one country may be eaſily tranſported into another; the Codex Alexandrinus, in the compaſs of a few years, was in Alexandria, Conſtantinople, and London; and that the Codex Bezæ has been ſubject to ſeveral migrations is not improbable from the various corrections both in the Greek and the Latin texts. Another hypotheſis has been propoſed, which will ſolve the ſeveral phenomena relative to the Codex Bezæ, as eaſily, or perhaps more ſo, than the preceding, viz. that it was written either at Conſtantinople, or in ſome city of the Greek empire in Europe, for the uſe of ſome perſon or community belonging to the Latin church, between the time of Conſtantine, and the final ſeparation of the Greek and Latin churches. During this period, it is probable that many Latin families removed from Italy, and ſettled in ſome of the principal cities of Greece; and perhaps whole communities attached to the Latin church exiſted in Conſtantinople for a conſiderable time after the removal of the ſeat of empire. It is alleged that the Codex Bezæ is exactly ſuch a MS. as we may ſuppoſe to have been written for the uſe either of a Latin community, or ſome perſon of diſtinction, ſettled in a city of the Greek empire. It was brought perhaps towards the cloſe of the Greek empire from Greece into Italy, where it was collated by Henry Stephens, if it is the ſame as the codex Stephani β. before it came into the hands of Theodore Beza. If we argue from the readings of the Codex Bezæ, to the place where it was written, we may conclude, that it was written either in Syria or in Egypt; for in many inſtances, where it departs from all other Greek MSS. it agrees with the old Syriac, the marginal readings of the new Syriac, the Coptic verſion, and the quotations of Origen. We need therefore, ſays Mr. Marſh, make only one addition to the laſt mentioned hypotheſis, an addition which agrees with the opinion of Dr. Semler, and we ſhall ſolve every phenomenon relative to the MS. in queſtion: viz. that the writer of the Codex Bezæ uſed ſeveral Greek MSS. from which he ſelected thoſe readings which appeared to him to be the beſt; and that one of theſe MSS. was of the Alexandrine edition. Semler has inſtituted a compariſon between the Cod. Cant. and the Coptic verſion, alſo with the Ethiopic, the Armenian, and the Alexandrian fathers; and the reſult of this inquiry is, that the Greek text of the Cod. Cant. belongs to the Alexandrine edition, and that the original from which it was copied was written in Egypt. With reſpect to the *uſe* that has been made of Beza's MS. we have already obſerved, that Stephens made extracts from it, though with no great accuracy, under the title Codex β. for the edition of the Greek Teſtament of 1550, and likewiſe Beza for his own edition, publiſhed in 1582. From his and the CLERMONT copy of St. Paul's Epiſtles, he publiſhed in this year his larger annotations. Since it was ſent to the univerſity of Cambridge, it has been more accurately collated by Junius. A fourth, and much more accurate collation of it was made at the inſtigation of Uſher, and the extracts were inſerted in the 6th volume of the London Polyglott. Mill collated it a fifth and ſixth time; but that his extracts are likewiſe frequently defective and ſometimes erroneous, appears from comparing them with Wetſtein's New Teſtament, and from a new collation that was made about the year 1733 by Mr. Dickenſon of St. John's college, which collation is at preſent in the library of Jeſus's college, where it is marked O Θ. 2. In Wetſtein's extracts are alſo many errors, as appears from comparing them with the MS. itſelf. As he took a copy of it, he probably collated, not the original while he was at Cambridge, but his copy after his return. Adler in his "Verſiones Syriacæ" has collated the "Verſio Syra Hieroſolymitana" with the readings of the Cod. Cant. and diſcovered in it 11 readings, that exiſt in no other Greek MS. now extant, 14 which are found only in one or two MSS. beſide the Cod. Cant. and 54 which are common to the Cod. Cant. and ſeveral other MSS. For this reaſon Dr. Harwood, in his edition of the Greek Teſtament, publiſhed in London in 1776, has regulated his text in the Goſpels and the Acts, chiefly according to the readings of the Cambridge MS. The copy which Wetſtein took of Beza's MS. in 1716, is not the only tranſcript which has been made of it; for Simon in his preface to the "Hiſtoire Critique du Texte du Nouv. Teſtament," relates, that he himſelf had a copy which had been ſent him from Cambridge. There is alſo a third copy which is preſerved in the library of Trinity college in Cambridge, and marked B. 10, 3. It is written on vellum, in ſmall characters with accents and marks of aſpiration. It is a large quarto, containing only the Greek text. This tranſcript muſt have been made ſome time in the 17th century. In the year 1787, the univerſity of Cambridge reſolved to print the whole MS. in letters of the ſame form and magnitude as the original hand-writing, and committed the publication to the care of Dr. Kipling. Accordingly this fac-ſimile was printed at Cambridge in 1793 in 2 vols. folio, under the title of "Codex Theodori Bezæ, Cantabrigienſis Evangelia et Acta Apoſtolorum complectens, quadratis literis, Græco-Latinus." The price to ſubſcribers was two guineas per vol. This work is printed in a ſplendid form: the paper is ſuperfine; the types are admirably cut; the ink is of uncommon blackneſs; and the impreſſion is ſcarcely paralleled. In theſe reſpects it ſurpaſſes Dr. Woide's fac-ſimile of the Alexandrian *copy*; but whether it does not yield to its Alexandrian rival in other particulars, we leave to the deciſion of competent judges. It is, however, a very valuable addition to the library of the Biblical critic. See Wetſtein's Prolegomena to his folio edition of the New Teſtament, vol. i. p. 28. Kuſter's edition of Mill's Teſtament, Proleg. p. 132. Mill Præf. in New Teſtament, Amſt. 1735. Kipling's Pref. Michaelis's Introd. to the New Teſtament. by Marſh, vol. ii. iii.

There are alſo other MSS. at Cambridge, for an account of which ſee Michaelis's Introd. by Marſh, ubi ſupra.

CAMBRIDGESHIRE, in *Geography*, is the name of one of the inland counties of England, having parts of Northamptonſhire, Huntingdonſhire, and Bedfordſhire, on the north-weſt, with Hertfordſhire, and Eſſex on the ſouth; Suffolk on the eaſt; and Norfolk on the north-eaſt. This tract of the iſland, with Suffolk and Norfolk, were inhabited, before the deſcent of the Romans, by a claſs of the Britons called Cenomanni, or Cenimaqui, one of the nations of the Iceni. Under the Romans, it formed a part of Flavia Cæſarienſis, and the Saxons made it a part of Eaſt Anglia. After various revolutions it was incorporated in Weſſex. By the latter people it was called Grantabrygſcyr, from the river Granta, which waters part of this diſtrict. The greateſt length of this county is about fifty miles; its greateſt breadth at the ſouthern extremity is ſomething more than twenty-five: its circumference is about 138. It contains nearly 443,300 acres, is divided into 17 hundreds, and has one city, ſix market-towns, 163 pariſhes, 16,451 houſes, and about 89,400 inhabitants, of whom 28,654 are perſons chiefly employed in agriculture, and 11,988 employed in trade, manufactures, and handicraft. The proportion of males to females is 44,081 to 45,265. The limits on the northern half are chiefly rivers and their communicating branches; on the ſouthern, the boundaries are wholly artificial. The principal rivers of Cambridgeſhire are the Ouſe and the Granta, or Cam. The former enters the county between Fenny Drayton and Erith; thence it runs eaſtward through the fens, till, at ſome diſtance above Denny abbey, it aſſumes a northerly direction, and paſſing Stretham, Ely, and Littleport, flows into Norfolk. The latter has three branches, the chief of which riſes near Aſhwell in Hertfordſhire; and enters this county to the weſt of Gilden-Morden, thence flowing to the north-eaſt, it receives ſeveral rivulets; and near Grantcheſter has its current enlarged by the united waters of its ſiſter ſtreams, which flow into this county from Eſſex. Hence, taking a northerly courſe, it glides through the gardens of the principal colleges at Cambridge, and having paſſed ſeveral villages, falls into the Ouſe at Harrimere, in the pariſh of Stretham. Beſides theſe rivers, whoſe channels appear to have been marked out by nature, there are numerous ſtreams in the northern part of the county, which were ſuggeſted by the conveniences, and formed by the induſtry of man. Theſe interſect the land in various directions; and by carrying off the ſurplus waters of the fens, have been the means of bringing many thouſand acres into cultivation. The chief drains are the old and new Bedford rivers, which are navigable for upwards of twenty miles, in a ſtraight line acroſs the county from Erith to Denver. A conſiderable part of the county on the northern and north-weſtern ſides, is occupied by the fens which conſtitute a part of the great Bedford level. It appears from the agricultural ſurvey of the county, that upwards of one third of Cambridgeſhire, or 150,000 acres, are ſtill in the condition of waſte and unimproved fen, the average value of which is little more than four ſhillings an acre. This is a full proof that the immenſe labour employed in the draining of the level, has not been attended with the ſalutary effects which the promoters of the various plans too fondly imagined. The towns and villages in the northern diviſion of the county, from the elevated ſpots on which they are built, appear like iſlands riſing from the midſt of low and level marſhes; and the churches, being generally on the higheſt parts, may be diſtinguiſhed at the diſtance of ſeveral miles. The cottages are in many places nothing more than mud walls covered with thatch. The application of the land is various. In thoſe parts which have been preſerved from the floods, or are only ſubject to occaſional overflowings, it has all the fertility of water meadows. The crops of oats are particularly exuberant, the produce being frequently from forty-five to ſixty buſhels an acre. Great quantities of wheat and cole-ſeed are alſo grown, and generally with a proportional increaſe. Many thouſand acres, particularly on the north-weſtern ſide, are appropriated to paſture. In the neighbourhood of Elm, Upwell, Outwell, &c. conſiderable quantities of hemp and flax are grown; but the culture of theſe articles, as a preparation for wheat, does not receive that attention which their importance demands. Some very fine butter is made on the dairy farms in this diſtrict, and is uſually ſold in the Cambridge markets in long rolls, called "yards," one of which weighs a pound. The vicinity of Cottenham is famous for a peculiar kind of new cheeſe, of a ſingularly delicious flavour; the ſuperiority of which is partly aſcribed to the mode obſerved in the management of the dairies, and partly to the nature of the herbage on the commons. In this part of the county many calves are ſuckled for the London markets. The ſalt marſhes in the north-weſtern corner of Cambridgeſhire are remarkably favourable for the growth of corn, but from their peculiar ſituation, their luxuriant produce is too frequently deſtroyed by the floods. The ſouth-eaſtern diviſion, reaching from Gogmagog hills to Newmarket, is bleak, heathy, and thinly inhabited; being connected with that vaſt tract of land, which, extending ſouthward into Eſſex, and northward acroſs Suffolk into Norfolk, forms one of the largeſt plains in the kingdom. This is chiefly applied to ſheep-walks; but ſome of its more fertile portions have been appropriated to the growth of barley. The ſouth and ſouth-weſtern parts of the county, conſiſting principally of elevated land, exhibit a remarkable contraſt to the northern diviſion, and are productive of fine wheat, barley, and oats; though the heaths and commons that interſect theſe diſtricts furniſh ſuſtenance to many thouſand ſheep, chiefly of the Norfolk, and Weſt country breeds. The valley through which the Cam flows from Steeple Morden to Walton, is called the Dairies, from being almoſt wholly appropriated to dairy farms. In ſome of the pariſhes bordering on Eſſex, ſaffron is cultivated. The ſoil of Cambridgeſhire is greatly diverſified. The rich marſhes in the vicinity of Wiſbech, conſiſt of a mixture of ſand and clay, or ſilt; in the fens, of a ſtrong black earth, or moor, lying on a gault or gravel, or turf-moor, and very favourable for the culture of oats and cole-ſeed; in the uplands, of chalk, gravel, loam, and tender clay, and clay upon a gault. The common manures are ſometimes aided by the application of oil-cake duſt, pigeons' dung decayed, woollen rags, ſoot, &c. The drill huſbandry, till lately, had been chiefly employed at Wimpole, on the eſtate of lord Hardwicke, but appears to be faſt ſpreading, and, with the introduction of ſome new agricultural machines, promiſes to become of eſſential ſervice. The rent of farms is generally from 50l. to 350l. per annum; but ſome in the neighbourhood of Wiſbech rent as high as 800l.; and one in the pariſh of Wood Ditton, is occupied at the rent of 1000 guineas yearly. The wood-lands are extremely ſmall, the whole quantity appropriated to timber throughout the county ſcarcely amounting to 1000 acres, and theſe principally ſcattered through the pariſhes of Stackworth, Wood Ditton, Linton, Bartlow, Boxworth, Wimpole, and Madingley. The greateſt part of the land is open field; but incloſures are rapidly taking place, new bills for that purpoſe being applied for, and obtained every ſeſſion of parliament. Manufactures are hardly known in this county; and, with the exception of thoſe perſons who obtain ſubſiſtence by making the celebrated white bricks, and coarſe pottery with the ſame clay, in the neighbourhood of Ely, moſt of the inhabitants are employed in agriculture: others derive ſupport from ſpinning yarn for the Norwich weavers. Cambridgeſhire, with the exception of a few pariſhes on the eaſt and north-eaſt ſide, which belong to the ſees of Norwich and Rocheſter, was taken from the ſee of Lincoln, by Henry the Firſt, in the year 1114, and made into a ſeparate dioceſe for the newly elected biſhopric of Ely. It ſends ſix members to parliament, viz. two for the ſhire, two for the town of Cambridge, and two for the univerſity; pays nine parts of the land-tax, and ſupplies the militia with 480 men. It is included in the Norfolk circuit.

CAMBRIN, a town of France, in the department of the ſtraits of Calais, and chief place of a canton, in the diſtrict of Béthune; the place contains 492, and the canton 15,288 inhabitants: the territory comprehends 90 kiliometres, and 18 communes.

CAMBRISOPOLIS, in *Ancient Geography*, an epiſcopal town of Aſia, in the patriarchate of Antioch, and ſubject to the metropolis of Anazarbum.

CAMBRO-British Music, national Welch tunes. Theſe ancient melodies, which till the eleventh century ſeem to have been traditional, after that period, were preſerved in writing. See Jones's Muſical and Poetical Relics of the Welch Bards. Theſe airs have a peculiar character, different from the Scotch and Iriſh, and are in high eſtimation with the natives, who have not yet forgiven the Saxons for driving them into the mountains, nor the Engliſh for ſlaying their bards, and robbing the principality of its independence. Moſt of the words which they ſing to their old tunes, are narratives of their ſtruggles for liberty.

CAMBULA, in *Botany*. (Rheed.) See Bignonia *catalpa*.

CAMBURG, in *Geography*, a town of Germany, in the circle of Upper Saxony, and principality of Altenburg; 28 miles W. of Altenburg, and 32 S.W. of Leipſick.

CAMBUS, in *Ancient Geography*, a river of Vindelicia, which commenced S. of Cambodunum, watered this town, and diſcharged itſelf into the Danube to the weſt of Gantia.

CAMBUSUM ostium, the name given by Ptolemy to the moſt weſtern mouth of the Ganges.

CAMBUVII montes, mountains of Greece in Macedonia, mentioned by Livy, who ſays, that the inhabitants of the country were called Voluſtanæ. He places them below the ſource of Aliacmon and near Panyaſus. Theſe mountains ſeparate the Elymiotide territory from Pelagonia.

CAMBYSENA, a country of Albania, between the rivers Cambyſes and Cyrus, and the mountains, according to Strabo. This was one of the prefectures of Armenia.

CAMBYSES, in *Biography*, king of Perſia, was the ſon of Cyrus the Great, and ſucceeded his father in the year B. C. 529. As ſoon as he was ſeated on the throne, he concerted an expedition againſt Amaſis, king of Egypt, who, as ſome ſay, had deceived him with reſpect to the grant of his daughter in marriage; or, according to others, becauſe he refuſed, after the death of Cyrus, to pay the ſame homage and tribute to his ſucceſſor, which he had agreed to render to Cyrus, and attempted to emancipate himſelf from the Perſian yoke. Cambyſes made great preparations for this expedition both by ſea and land: but Amaſis died in the interval of four years, and was ſucceeded by his ſon Pſammenitus. Cambyſes begun with the capture of Peluſium; and in order to ſecure his ſucceſs, had recourſe to the following ſtratagem. Being informed that the whole garriſon conſiſted of Egyptians, he placed in the front of his army a great number of cats, dogs, ſheep, and other animals, which were deemed ſacred by that nation, and then ſtormed the city. The ſoldiers of the garriſon not daring either to fling a dart or ſhoot an arrow for fear of injuring ſome of theſe animals, Cambyſes became maſter of the place without oppoſition. In a ſubſequent battle with the army of Pſammenitus, he proved victorious, and took the king captive. Having purſued the fugitives to Memphis, he ſoon took the place, and becauſe the inhabitants had maſſacred the herald and his retinue, whom he had ſent to require their ſurrender, he cauſed as many of the prime nobility as they had deſtroyed to be publicly executed; and he ordered Pſammenitus to be put to death. Upon this Egypt ſubmitted to the conqueror; and the Libyans, Cyrenians, and Barceans ſent ambaſſadors with preſents to teſtify their ſubjection, and to conciliate his favour. At Sais, which was the burying place of the kings of Egypt, he cauſed the body of Amaſis to be taken out of its tomb, and having expoſed it to various indignities, he ordered it to be burnt, in direct oppoſition to the cuſtoms of the Perſians and Egyptians. In the following year, which was the ſixth of his reign, he determined to make war againſt the Ammonians and Ethiopians, and leaving his Greek auxiliaries to ſecure his conqueſts, he purſued the object of his expedition. As ſoon as he arrived at Thebes in Upper Egypt, he ſent a detachment of 50,000 men againſt the Ammonians, with orders to ravage the country, and to deſtroy the famous temple of Jupiter Ammon; but in their paſſage through the deſert they were overwhelmed by a deluge of ſand and totally deſtroyed. Cambyſes himſelf advanced with the main body of his army towards Ethiopia; but as he had neglected to provide neceſſary ſubſiſtence for his numerous followers, they were ſoon reduced to the moſt dreadful indigence and diſtreſs; ſo that, after having devoured all their beaſts of burden, and every kind of vegetable which they could find, they were under a neceſſity of ſacrificing every tenth man as food for their companions. The king, however, for ſome time perſiſted in his mad deſign; but at length apprehenſive of perſonal danger, he returned to Thebes with the ſhattered remnant of his large hoſt. Here, irritated by his diſappointment, he pillaged the rich and magnificent temples of the city, and ſet them on fire; and it is ſaid that their wealth was ſuch, that the remains that were ſaved from the flames, amounted to 300 talents of gold, and 2300 talents of ſilver. He likewiſe carried away the famous circle of gold that encompaſſed the tomb of king Ozymandias, which is reported to have been 355 cubits in circumference, and to have exhibited the motions of the ſeveral conſtellations. From Thebes he returned to Memphis, where he indulged to its full extent his naturally ferocious and ſavage diſpoſition, by deſtroying the Egyptian prieſts, and the worſhippers of their god Apis, and killing this ſacred ox. To this outrage againſt humanity and the rites of their religion, the Egyptians attributed his ſubſequent inſanity: but his general conduct both before and after this event, afforded ſufficient evidence of his derangement and his cruelty. Jealous of his brother Smerdis, he ordered him to be put to death; and he then married his own ſiſter, Meroe. Having previouſly conſulted the Perſian judges, whether any law ſubſiſted that forbade this inceſtuous marriage, they, diſapproving of the act, but at the ſame time fearful of the king's violent temper, returned this artful reply: "That they had no law indeed which permitted a brother to marry his ſiſter, but they had a law which allowed the king of Perſia to do what he pleaſed." This beautiful and beloved wife taking occaſion to refer to the fate of her brother Smerdis, excited the rage of this brutal prince, ſo that he killed her, though in a ſtate of pregnancy, by a kick in the belly. Another ſavage act of which he was guilty, was that of ſhooting to the heart the ſon of one of his principal officers and favourites, who had in a delicate manner reproved him for his intemperance. Having taking out the heart, which the arrow had pierced, he preſented it to the father, and aſked him in an inſulting manner, "have I not a ſteady hand?" to which the abject parent replied, "Apollo himſelf could not have ſhot better." "Sceleratius," ſays Seneca, after reciting this ſtory from Herodotus, "telum illud laudatum eſt, quam miſſum." About the ſame time, he cauſed ſeveral of his principal followers to be buried alive, and daily ſacrificed ſome or other of them to his wild fury. Crœſus, who remonſtrated againſt theſe proceedings, was ordered to be put to death; and thoſe who delayed executing the royal mandate, under a conviction that the king would repent of it, were ordered to be ſlain, becauſe they diſobeyed his command, though at the ſame time he expreſſed his joy that Crœſus was alive. In conſequence of theſe and ſimilar proceedings, a conſpiracy was formed, during the abſence of Cambyſes from his own country, for ſeizing the throne, by Smerdis, one of the Magi, under a pretence that he was that Smerdis whom his brother had cauſed to be put to death. Cambyſes received this news whilſt he was in Syria, on his return from Egypt to Perſia: and on this occaſion the name of Smerdis excited compunction and terror, whilſt he recollected the fratricide he had committed. He prepared, however, for cutting off the uſurper; but as he was mounting his horſe for this expedition, his ſword ſlipped out of its ſcabbard, and gave him a wound in the thigh, which occaſioned his death in the eighth year of his reign, B. C. 522. Cambyſes is ſuppoſed to be referred to in Scripture, under the name of Ahasuerus. Herodotus, lib. iii. Rollin's Anc. Hiſt. vol. ii. 177.

Cambyses was alſo the father of Cyrus, who is ſaid by Herodotus to have been a Perſian of mean extraction; but by Xenophon to have been a king of Perſia. He married Mandane, the daughter of Astyages.

Cambyses, in *Ancient Geography*, a river of Albania, which roſe in mount Caucaſus, and diſcharged itſelf, after purſuing its courſe between the Albus fluvius and the Cyrus, into the Caſpian ſea.

CAMBYSU, a town ſituate on the Red ſea, in the gulf of Hercopolis, near the place where the Iſraelites paſſed this ſea under the conduct of Moſes. Pliny ſays that it was ſituated between Nelos and Marchadas.

CAMDEBOO, in *Geography*, a loan-farm in the diſtrict of Graaf Reynet, in Southern Africa; which extends along the feet of the ſnowy mountains from the Droſdy to Bruyntjes Hoogté, and is chiefly compoſed of Karroo plains, that are, however, extremely fertile in the chaſms, down which the ſtreams of the mountains conſtantly flow. The oxen are large and ſtrong, and the ſheep little inferior to thoſe of the ſnowy mountains. The beautiful animal, the *Gnoo*, is frequently ſeen bounding over the plains of Camdeboo, and ſpring-boks and harte-beeſts are very plentiful. Barrow's Africa, vol. ii. p. 374.

CAMDEN, William, in *Biography*, an eminently learned antiquarian and hiſtorian, was born in May, 1551, in London, where his father, a native of Litchfield in Staffordſhire, was a member of the company of painter-ſtainers. His mother was of the ancient and reſpectable family of the Curwens in Cumberland. After having received the firſt rudiments of his education in Chriſt's hoſpital, and at St. Paul's ſchool, where he made a very conſpicuous proficiency, he was entered as a ſervitor in Magdalen college, Oxford, at the age of 15 years; and became ſucceſſively a member of Broadgate hall (now Pembroke college) and of Chriſt-church, depending for his ſupport chiefly on the kindneſs of friends, and more particularly on that of his liberal patron, Dr. Thornton, canon of Chriſt church. Failing by the intrigue of the popiſh party to obtain a fellowſhip in the college of All-Souls, and to be admitted bachelor of arts, he removed to London, and proſecuted his ſtudies under the patronage, and by the aſſiſtance of Dr. Gabriel Goodman, dean of Weſtminſter, and his nephew, Mr. Godfrey Goodman, who ſupplied him with both money and books. In 1573 he returned to Oxford, and obtained the degree which he had before unſucceſsfully ſolicited. By the intereſt of his friend dean Goodman, he was appointed, in 1575, ſecond maſter of Weſtminſter ſchool, and diſcharged the duties of that office with great diligence, capacity, and ſucceſs, ſo that he acquired a high degree of reputation among learned perſons both at home and abroad. His leiſure hours at this time were devoted to his favourite ſtudy of antiquities; and with a view to the great work which he afterwards executed, he began to make collections, from every ſource of information to which he could have acceſs, of ſuch materials as might ſerve to illuſtrate the hiſtory and antiquities of Britain. For this purpoſe he made a tour, in 1582, through ſome of the eaſtern and northern parts of the kingdom; and he alſo eſtabliſhed a correſpondence with perſons moſt eſteemed for their learning and judgment, both in his own country and in other nations. The firſt reſult of his reſearches appeared in 1586, under the title of "Britanniæ, ſive florentiſſimorum Regnorum Angliæ, Scotiæ, Hiberniæ, et Inſularum adjacentium ex intimâ Antiquitate Chrographica Deſcriptio;" i. e. "Britain, or a Chorographical Deſcription of the moſt flouriſhing Kingdoms of England, Scotland, and Ireland, with the adjacent Iſlands, from the moſt remote Antiquity," Lond. 8vo. In the dedication of this work to lord-treaſurer Burleigh, Camden gratefully acknowledges the benefits he had derived from his patronage and aſſiſtance. For the further improvement of this work, which was one of the great objects of his life, he took journies into the weſt of England, and alſo into Wales in 1589 and 1590; he conſulted the archives of the kingdom; and he obtained the beſt information he could procure with reſpect to the genealogies and memoirs of ancient families; and he thus enlarged and enriched the ſubſequent editions of his "Britannia," which became ſo popular, that the fourth was printed in 1594, in 4to. In the preceding year he ſucceeded Dr. Edward Grant, who reſigned the office of head-maſter of Weſtminſter ſchool. Notwithſtanding his profeſſional engagements, and his ill health, he employed the intervals that occurred in journies of reſearch and diſcovery, pertaining to his main object. He alſo paid due attention to his office as an inſtructor of youth; for in 1597 he publiſhed, for the uſe of his ſchool, a Greek grammar, which, though not an original work, but an abridgment of a copious one, compoſed by his predeceſſor, Dr. Grant, was highly approved, and long continued to be a ſtandard book. In 1691 this grammar, entitled "Grammatices Græcæ Inſtitutio compendiaria in uſum Regiæ Scholæ Weſtmonarienſis," 8vo. had paſſed through very nearly 100 impreſſions. Camden ſeems to have been ſo much attached to his profeſſion, in the exerciſe of which he was highly eſteemed and reſpected, that, though he was offered the place of a maſter of requeſts, he declined accepting it. But when by the intereſt of ſir Fulk Greville, the vacant poſt of Clarencieux king of arms was conferred upon him, this office was ſo congenial to his taſte and purſuits, and afforded him ſo much leiſure for proſecuting his favourite ſtudies, that he ſurrendered his connection with Weſtminſter ſchool. As he was now more at liberty than when he had the charge of the ſchool, he took a journey, in 1600, into the north, as far as Carliſle, with his friend Mr., afterwards ſir, Robert Cotton; and in the ſame year he publiſhed an account of all the monuments in Weſtminſter abbey, with their inſcriptions, &c. In this year alſo appeared the fifth edition of the "Britannia," with an apology annexed to it, containing a reply to the objections urged againſt it by Rafe Brooke, York-herald. In 1603 Camden cauſed to be publiſhed at Frankfort, in folio, a collection of our ancient hiſtorians; ſome never before publiſhed, and others rendered more accurate and complete, under the title of "Anglica, Normannica, Hibernica, Cambrica, à Veteribus deſcripta, &c.;" and in 1605 appeared his "Remaines of a greater Work concerning Britain, the Inhabitants thereof, their Languages, Names, Surnames, Empreſſes, wiſe Speeches, Poeſies, and Epitaphes," Lond. 4to. The work was dedicated to his much valued friend and patron, ſir Robert Cotton; and with a view of evading ſuch attacks as had been made upon his "Britannia," he depreciates this collection, calling it "the outcaſt of a greater and more ſerious work, the pitifulneſs and ſillineſs whereof would ſecure it from envy, which only reaches at eminence." Accordingly, he ſubſcribed it only with the final letters of his name. But we have reaſon to believe, that, in reality, he did not think meanly of this collection, dedicated to one of his beſt friends, and a competent judge of its contents; and well received by the public, as it paſſed through ſeveral editions. Camden alſo compoſed many brief eſſays on Britiſh antiquities, chiefly at the requeſt of the Society of Antiquaries, of which he was a member. Thoſe that are ſtill extant may be found in the collections of Thomas Hearne. In 1606 a correſpondence commenced between Camden and the famous preſident De Thou, which continued for 11 years, till the death of the latter, and in the courſe of which the former communicated many uſeful notices concerning the affairs of Great Britain. On the diſcovery of the gunpowder plot, Camden was employed by king James to draw up an account of it in Latin, for the information of foreigners; and this ſervice was performed by him in a ſatisfactory manner. It was publiſhed in 1607, 4to. by the king's printer, in Latin, Greek, and Hebrew: and not long after it was inſerted in the liſt of prohibited books by the inquiſition at Rome. In this year he was confined for ſeveral months in conſequence of an injury received by a fall from his horſe; and he employed this time in preparing for the preſs and publiſhing a final and complete edition in folio of his "Britannia." It was this edition that occaſioned him to be diſtinguiſhed as the "Varro," the "Strabo," and the "Pauſanias" of Britain; and it was from this edition that the Engliſh tranſlation of Dr. Philemon Holland was made in 1611, and others of later date. The "Britannia" remains to this day a ſtandard work; and the tranſlations of it in the ſucceſſive editions of biſhop Gibſon, firſt publiſhed in 1695, and of Richard Gough, eſq. publiſhed in 3 large vols. folio in 1789, have been ſwelled by corrections and additions to books of great bulk and importance. Camden, with a mind diſcharged from conſtant attention to what may be denominated his "Opus majus," began, in 1608, to digeſt the materials which he had been long collecting for a hiſtory of the reign of queen Elizabeth, to which he had been firſt excited by his old patron, the lord-treaſurer Burleigh. Whilſt he was proſecuting this work, a proſpect of new preferment, as one of the profeſſors of hiſtory in a new college of polemics, propoſed by Dr. Sutcliffe to be erected at Chelſea, preſented itſelf; but the inſtitution, though patronized by king James, was never eſtabliſhed. He therefore directed his whole attention to the completion of his hiſtory, the firſt part of which, after having been approved by king James, was printed in 1615, under the title of "Annales Rerum Anglicarum et Hibernicarum regnante Elizabethâ ad Annum Salutis, 1589," Lond. fol. The reputation of the author both at home and abroad was much advanced by this publication; but it did not eſcape animadverſion; and his repreſentation of ſome tranſactions, particularly thoſe relating to Ireland, drew upon him ſome virulent attacks, to which, however, he made no reply. He cloſes his preface, in which he gives an account of his ſources of information, and of his reaſon for entitling his hiſtory "Annals," with this memorable declaration: "Whatever it be, I dedicate and conſecrate it at the altar of truth, to God, to my Country, and to Poſterity." The animadverſions made on the firſt volume diſcouraged the author from proceeding to publiſh the ſecond part during his life; and, therefore, after finiſhing it in 1617, he kept the original by him, which was preſerved in the Cotton library, and ſent an exact copy to his friend Mr. Dupuy, who faithfully executed the order for publiſhing it after his death. This hiſtory, at and after the time of its publication, has undergone ſome ſevere ſtrictures. Some of the moſt candid judges, who have thought it, upon the whole, a valuable hiſtorical compoſition, have been of opinion, that it contains too favourable a repreſentation of the reign of queen Elizabeth. Le Clerc, in his "Bibliotheque Choiſie" (tom. 8. p. 139. 158.), has made ſome obſervations on what Camden has ſaid concerning Buchanan, and Mary queen of Scots, and has ſhewn, that thoſe parts of his work are written under the influence of prejudice or miſinformation. He farther intimates, that Camden was miſled by the good opinion he entertained of king James I. and his zeal for his ſervice; and it appears, that his ſubmiſſive loyalty led him to pay a regard to the judgment of his prince, to which it was not entitled. Dr. Robertſon alſo obſerves (Hiſt. of Scotland, vol. ii. p. 388, &c.), that Camden's repreſentation of ſome important tranſactions relative to queen Mary are very ill founded, and that this part of his hiſtory is leſs accurate than any other. Hume, however (Hiſt. of England, vol. vi. p. 195, 8vo.), ſays, that "Camden's hiſtory of queen Elizabeth may be eſteemed good compoſition both for ſtyle and matter. It is written with ſimplicity of expreſſion very rare in that age, and with a regard to truth. It would not perhaps be too much to affirm, that it is among the beſt hiſtorical productions which have yet been compoſed by any Engliſhman."

After the completion of his hiſtory, Camden paſſed his time in literary leiſure and in the exerciſe of his heraldic office; his ſummers were generally ſpent at Chiſlehurſt in Kent, and his winters at his houſe in Weſtminſter. One of the laſt acts of his life was that of founding a hiſtory-lecture at Oxford; for the ſupport of which he appropriated the valuable manor of Bexley in Kent, which he made over to the univerſity in 1622: and he appointed Mr. Degory Wheare as the firſt profeſſor. For this eſtabliſhment the univerſity, which had been ſlow in conferring favours upon him, when a young man, honoured him, after his death, with ſingular teſtimonies of reſpect. Camden died at Chiſlehurſt in November, 1623, in the 73d year of his age, and was buried with great heraldic pomp in Weſtminſter abbey, near the learned Caſaubon, and over againſt the celebrated Chaucer. Near the place was erected a monument of white marble, with his effigies to the middle, and in his hand a book with "Britannia" inſcribed on the leaves; under which there is an elegant inſcription. As an antiquarian, Camden's character has been long eſtabliſhed; ſo that he may be juſtly reckoned as the father of Britiſh antiquities, and the materials which he collected have ſerved as a baſis for the accumulation of further knowledge on the ſubject. His merits as an hiſtorian have been already ſtated. For the elegancies of literature he is ſaid to have had a taſte, ſo that he wrote Latin verſe with purity and harmony. Biſhop Gibſon, in his life of Camden, has given a conciſe ſketch of his character in the following words: "In his writings he was candid and modeſt, in his converſation eaſy and innocent, and in his whole life even and exemplary." But neither his extenſive learning, nor his high reputation, could defend him from the envy of his enemies while living, or his memory from inſults after his death. Biog. Brit.

Camden, in *Geography*. See Campden.

Camden, or Cambden, a county of North America, in Edenton diſtrict, North Carolina, ſituate in the N.E. corner of the ſtate. It has 4033 inhabitants, including 1038 ſlaves. Its chief town is Joneſborough.

Camden, a diſtrict of the upper county of South Carolina, bounded by Cheraws diſtrict on the N.E., Georgetown diſtrict on the S.E., and the ſtate of North Carolina on the N., and divided into the following counties, *viz.* Clarendon, Richland, Fairfield, Claremont, Lancaſter, Kerſhaw, and Salem. It is 82 miles from N. to S. and 60 from E. to W., and contains 38,265 inhabitants, including 8865 ſlaves. It is watered by the Wateree, or Catabaw river, and its branches: the upper part is variegated with hills, generally fertile and well watered. It produces Indian corn, wheat, rye, barley, tobacco, and cotton. The Catabaw Indians live in the northern part of this diſtrict.

Camden, the chief town of Camden diſtrict, in South Carolina, is ſeated on the E. ſide of Wateree river, 35 miles N.E. of Columbia, 55 S.W. of Cheraw, 120 N. by W. of Charleſtown, and 643 S.W. of Philadelphia. It is a regular town, and contains about 120 houſes, an epiſcopalian church, a court-houſe and gaol. The navigable river on which it is ſituated, enables it to carry on a briſk trade with the back country. N. lat. 34° 20′. W. long. 80° 38′.

Camden, a county in the lower diſtrict of Georgia, at the ſouth-eaſt corner of the ſtate, on St. Mary's river, containing 305 inhabitants, of whom 70 are ſlaves. The chief town is St. Patrick's.

Camden, a ſmall poſt-town on the weſtern ſide of Penobſcot bay, in the diſtrict of Maine, and the ſouth-eaſternmoſt townſhip of Lincoln county, having Thomas-town on the S.W.; 35 miles N.N.E. from Pownalborough, and 228 miles N.E. from Boſton.—Alſo, a village in the county of Kent, and ſtate of Delaware, about four miles S.W. from Dover, and five north-weſterly from Frederica.

CAMEA. See Camæa.

CAMECHIA, in *Ancient Geography*, the name of a town in Albania, mentioned by Ptolemy.

CAMEHUIA. See Camaieu.

CAMEL, in *Geography*. See Alan and Camelford.

Camel, *mount*, lies on the W. coaſt of New Zealand, in the South Pacific Ocean, and is remarkable on account of the land that is contiguous to it being moſtly low and barren; and as it is near the north end, it is ſeen in almoſt every direction, the iſland being, in this part, very narrow. The obſerved latitude is 34° 20′ S.

Camel, in *Mechanics*, a kind of machine uſed in Holland for raiſing or lifting ſhips, and invented by Bakker, a burgomaſter of Amſterdam, in the year 1688, or 1690. It took the denomination from its heavineſs or ſtrength.

Its uſe is to raiſe veſſels, in order to bring them over the Pampus, which is a paſſage between two ſand-banks, oppoſite to the mouth of the river Y, about ſix miles from the city of Amſterdam, where the ſhallowneſs of the water hinders large ſhips from paſſing. On this account, veſſels which are outward-bound, take in before the city only a ſmall part of their cargo; and they receive the reſt when they have paſſed the Pampus. For the ſame reaſons, thoſe which are homeward-bound, muſt, in a great meaſure, unload before they enter it. Many meaſures were adopted to prevent the accumulation of ſand in this paſſage; but they were ineffectual. About the year 1672, they had no other remedy for this evil beſides that of faſtening to the bottoms of ſhips large cheſts filled with water, which was afterwards pumped out, ſo that the ſhips were buoyed up, and rendered ſufficiently light to paſs the ſhallow. By this method, the Dutch carried out, with the utmoſt difficulty, their numerous fleet to ſea in the above-mentioned year. This plan, however, gave riſe, ſoon after, to the invention of the camel, by which the labour was much facilitated. This machine conſiſts of two half-ſhips, built in ſuch a manner that they can be applied, below water, on each ſide of the hull of a large veſſel. On the deck of each part of the camel there are a great many horizontal windlaſſes; from which ropes proceed, through openings, in the one half, and, being carried under the keel of the veſſel, enter ſimilar openings in the other, from which they are conveyed to the windlaſſes on its deck. When they are to be uſed, as much water as may be neceſſary is ſuffered to run into them; all the ropes are caſt looſe; the veſſel is conducted between them; and large beams are placed horizontally through the port holes, with their ends reſting on the camel, on each ſide. When the ropes are made faſt, ſo that the ſhip is ſecured between the two parts of the camel, the water is pumped from it; and it then riſes, and raiſes the ſhip along with it. Each half of the camel is generally 127 feet in length; the breadth, at the one end, is 22 feet, and at the other, 13. The hold is divided into ſeveral compartments, that it may be kept in equipoiſe, while the water is flowing into it. An Eaſt India ſhip, that draws 15 feet of water, can, by the help of this machine, be made to draw only 11; and the heavieſt ſhips of war, of 90 or 100 guns, can be ſo much lightened as to paſs without obſtruction, over all the banks of the Zuyder-zee.

Leopold aſcribes the invention of this machine to Cornelius Meyer, a Dutch engineer, who, towards the end of the 17th century, was invited to Rome by the Apoſtolic chamber, to cleanſe the Tiber, and render it navigable. In a work entitled, "L'Arte di reſtituire à Roma la tralaſciata Navigazione del ſuo Tevere," Rom. 1683, fol. and deſcribing his inventions, he propoſes a method for carrying large ſhips over ſhallows, which bears a conſiderable reſemblance to that in which the camel is employed; for he ſays, that a veſſel muſt be conſtructed in ſuch a manner as to embrace the hull of the ſhip, like a caſe; and that when placed under the ſhip, it will raiſe it up. But though this machine of Meyer is founded on the ſame principles with thoſe of the camel, it is different, as it conſiſts of one piece, and can be placed under a ſhip only in a dock, by the help of a number of ſcrews. It does not appear that Meyer's machine was ever tried or employed. On the other hand, we are aſſured, on the teſtimony of Bakker, the original inventor of the camel, recorded in 1692, and ſtill preſerved, that in the month of June, when the water was at its uſual height, he conveyed, in the ſpace of 24 hours, by the help of his machine, a ſhip of war, 156 feet in length, from Enkuyſen hooft to a place where there was ſufficient depth; and in 1693, he raiſed a ſhip ſix feet by the help of this machine, and conducted her to a place of ſafety. At later periods, the Dutch invention has been employed in other countries. The Ruſſians uſe camels to carry ſhips over the ſhoals that are formed in the Neva; and they have them of various ſizes. Bernouilli ſaw one, each half of which was 217 feet in length, and 36 in breadth. Camels are likewiſe uſed at Venice. Ships of war, however, to which this machine is applied, muſt unavoidably ſuſtain injury; and it is well known, that the ports of a ſhip which had been raiſed by the camel, were ſo much ſtrained, that they could not afterwards be cloſely ſhut. The principle upon which this machine acts, ſo as to anſwer the purpoſe, is that of ſpecific gravity. Muſchenbroek's Introd. ad Phil. Nat. vol. ii p. 520. Beckmann's Hiſt. Invent. vol. iii. p. 337, &c.

Camel, in *Zoology*. See Camelus.

Camel-*bird*, in *Ornithology*. See Camelus.

Camel's-*hay*, in *Botany*. See Andropogon.

CAMELANI, in *Ancient Geography*, a people of Italy in Umbria, who, according to Hardouin, inhabited the town called *Camilianum*.

CAMELEON, in *Zoology*. See Chamæleon.

Cameleon, Chamæleon, in *Aſtronomy*, one of the conſtellations of the ſouthern hemiſphere, near the pole, and inviſible in our latitude. The ſtars in this conſtellation, according to Sharp's Catalogue, are ten.

CAMELFORD, in *Geography*, is a very ancient, but inconſiderable borough-town of Cornwall, England, ſituated in a dreary, bleak, and almoſt deſolate part of the county: like moſt of the Corniſh boroughs, it has ſcarcely any other claim to public notice, than the privilege of returning two members to parliament. Theſe are elected by the mayor, burgeſſes, and freemen, which do not exceed 20 perſons. It began to ſend members in the reign of Edward VI., and this liberty was confirmed by Mary. It was made a borough by a charter from Richard duke of Cornwall, (when he was king of the Romans,) who granted it a market and a fair. Theſe privileges were afterwards confirmed by his brother Henry III. It was incorporated by Charles I. The whole town contains only 100 houſes; and the pariſh-church is at Lanteglos, about one mile diſtant. This neighbourhood has been, according to the ſtatement of many hiſtorians, the theatre of two deſperate battles; one between the Britons and the Saxons, and the other between the famous Britiſh Pen-dragon, Arthur, and his nephew Modred, or Medrawd, who, after an adulterous intercourſe with Arthur's queen Guenora, rebelled againſt his uncle, and ſought to deprive him of his kingdom. The war laſted ſeveral years, and various battles were fought; but the deciſive conflict at length occurred at Camlan, (probably Caben-alan, the crooked river) where, after two days' engagement, with uncommon ſlaughter, Modred was killed, and Arthur himſelf mortally wounded. See Arthur. The ſite of the battle is diſputed by different hiſtorians; though, from ſome local circumſtances, we are inclined to fix it near the village of Camel, which is within ſight of Glaſtonbury abbey, in Somerſetſhire. Camelford is 228 miles weſt from London; and has a market on Friday.

CAMELIDES, in *Ancient Geography*, iſlands of the Mediterranean Sea, on the coaſt of Aſia Minor. Pliny places them on the coaſt of Ionia, in the vicinity of Miletum.

CAMELINA, in *Botany*, (ſive Myagrum. Dod. pempt. 532. Lob. ic. 224. Venten. iii. p. 14. C. ſativa, Crantz. Auſt.) See Myagrum *ſativum*.

Camelina (Myagrum alterum. Lob. ic. 225.) See Eryſimum *Cheiranthoides*.

CAMELIOMAGUS, in *Ancient Geography*, a place of Italy, in the northern part of Liguria, to the weſt of Placentia.

CAMELITA, Bos, in *Zoology*. See Bison.

CAMELLIA, in *Botany*, (named in honour of George Joſeph Kamel, a Jeſuit, whoſe name has been latinized into Camellus. He is the author of Syllabus Stirpium in inſula Luzone Philippinarum, annexed to the third volume of Ray's Hiſtoria Plantarum) Linn. gen. 848. Schreb. 1145. Willd. 1302. Juſſ. 262. Vent. 2.447. Claſs and order, *monadelphia polyandria*. Nat. ord. *Columniferæ*, Linn. *Aurantia*, Juſſ. *Ebenaceæ*, Vent.

Gen. Ch. *Cal.* perianth many-leafed, imbricated: leaves roundiſh, very blunt: the inner ones gradually larger, deciduous. *Cor.* petals five to ſeven, large, inverſely egg-ſhaped, adhering at the baſe. *Stam.* filaments numerous, erect, coaleſcing below into a crown larger than the ſtyle, unconnected above, ſhorter than the corolla; anthers ſimple. *Piſt.* germ roundiſh; ſtyle awl-ſhaped, the length of the filamens; ſtigmas from three to five, acute. *Peric.* top-ſhaped, woody, furrowed, with as many cells as furrows, ſeparated by very ſlender partitions. *Seeds:* nuts one or two in each cell.

Eſſ. Ch. *Calyx* many-leaved, imbricated; inner leaves larger.

Sp. 1. C. *japonica*. Japan roſe. Linn. Sp. 982.

Thunb. Japan. 272. Jacq. ic. rar. 3. Tab. 553. Curtis, Mag. 42. Lam. Illuſt. Pl. 594. (Tſubakki. Kæmp. amæn. Tab. 851, 852. Thea chinenſis flore roſeo, Pet. gaz. Tab. 33. fig. 4.) "Leaves acutely ſerrated, acuminate." A lofty, large, evergreen tree. *Trunk* covered with an aſh-coloured bark; branches round and ſmooth. *Leaves* alternate, egg-ſhaped, acute, ſhining on both ſides, thick and ſtiff, paler green beneath, on ſhort petioles. *Flowers* large, beautiful, thoſe of the plants which have been raiſed in Europe, lively red, but in their native country they exhibit a variety of colours, nearly ſeſſile, generally ſolitary, but ſometimes two or more together; petals thickiſh, uniting at the bottom into a tube full of nectareous juice; ſtamens about fifty. Stigma unequally five-cleft. Its flowers readily become double, in which ſtate they often occur in Chineſe paintings. A native of China and Japan, introduced into England before 1742 by Robert James lord Petre. It was for a long time very ſcarce, and as it bore a high price, was generally treated as a ſtove plant, but Mr. Curtis obſerves, that it appears a very proper plant for the conſervatory, and may hereafter, probably, be treated as a lauriſtina or magnolia. It is propagated either by layers or cuttings. Petiver conſidered it as a ſpecies of tea-tree, to which it is certainly nearly allied. 2. C. *ſaſanqua*, Thunb. jap. 273. Kæmpf. amæn. 853. "Leaves obtuſely ſerrated, emarginate." A tree of a middling ſize. *Stem.* much ſmaller, and more ſlender than that of the preceding ſpecies. *Leaves* thinner and narrower. Flowers many times ſmaller, ſolitary, terminating the branches; calyx of five or ſix leaves; petals from five to ſeven, ſnow-white, deciduous. The leaves dried in the ſhade have a ſweet ſmell, and are mixed with tea to give it a grateful odour: a decoction of them is uſed by the women to waſh their hair with. This ſpecies ſo reſembles the tea-plant, that it is diſtinguiſhed chiefly by the coaleſcing ſtamens, and this, as Thunberg obſerves, is ſcarcely a ſufficient mark of diſtinction, ſince the ſtamens coaleſce only at the baſe, and ſometimes ſeem to be diſtinct. A native of Japan. The Chineſe call this plant "Chawhaw," or flower of tea. It yields a nut, from which is expreſſed an eſculent oil, equal to the beſt which comes from Florence. On this account, it is cultivated in great abundance; and is particularly valuable from the facility of its culture in ſituations fit for little elſe. See ſir George Staunton's Embaſſy to China, vol. ii. p. 467. He has given a drawing of the plant. 3. C. *drupifera*, Lour. Cochin. 141. "Leaves oblong-egg-ſhaped, ſlightly ſcollopped; flowers two or three together, terminating; drupes four-celled." A middle ſized tree with ſpreading branches. *Leaves* acuminate, ſmooth, hard, ſmall, alternate, petioled. *Flowers* white; petals eight, oblong, emarginate: ſtyle quadrifid, the length of the ſtamens. *Drupe* roundiſh, with a grooved, four-celled nut, and roundiſh kernels. The fruit is equal in ſize to the walnut, and is not much unlike it, but is not eſculent. The oil expreſſed from the nuts is uſed by the natives to anoint their hair, and for various medical purpoſes; it has a pleaſant odour, and does not ſoon become rancid. A native of Cochinchina. This plant is taken up by profeſſor Martyn as a camellia, from Loureiro; but Boſc aſſerts, that its botanical characters are far remote from thoſe of this genus, and with his uſual parſimoniouſneſs, gives no further obſervation on this ſubject.

CAMELOBOSCI, in *Ancient Geography*, a people of Aſia, placed by Ptolemy in Carmania, and ſurnamed Soxotæ.

CAMELOPARDALIS, in *Zoology*, a genus in the Pecora order of Mammalia, inſtituted by Gmelin, upon the authority of late writers, for the reception of that curious animal the Giraffe, or Camelopardi. The character of the genus, as laid down by this author, conſiſts in having the horns very ſimple, covered with ſkin, and terminated by a tuft of black hair; the fore teeth in the lower jaw eight in number, broad, thin, and the outer one on each ſide deeply bilobate.

Linnæus deſcribes this creature in the twelfth edition of his Syſtema Naturæ, as a kind of cervus, or deer, under the ſpecific title of Camelo-pardalis; a name by which it was known among the earlier Latin writers, as Strabo and Oppian. Linnæus was not ſingular in conſidering the giraffe as a ſort of cervus; he had the example of Geſner, and other nomenclators before him. Geſner affirms (as he tells us), on the credit of Belon, one of the earlieſt among modern naturaliſts, who has attended particularly to this animal, that the giraffe ſheds his horns like the deer. Buffon complains that no ſuch paſſage as Geſner quotes is to be found in any part of Belon's works; but be this as it may, Linnæus was miſled by this and other accounts of the animal to believe it muſt be of the deer kind. Since the time of Linnæus, naturaliſts are become better acquainted with this animal: it has been diſcovered, that the horns are not deciduous as in the deer, or at leaſt there is every reaſon to think they are not. Theſe horns are of a texture altogether different, not only from thoſe of the animals of that kind, but from all the other known kinds of horned quadrupeds. Anatomiſts obſerve, that theſe horns are only porous bony excreſcences, forming, as it were, a part of the ſkull, a pretty ſtrong proof that they are not deciduous, and cannot be ſhed like the horns of the deer.

From the ſtructure of theſe horns, and the peculiar arrangement of the teeth, it is clear the giraffe is an animal of another genus diſtinct from that of cervus, in which Linnæus places it. Gmelin removes it from the cervus genus in the laſt edition of the Syſtema Naturæ, to that of Camelopardalis, where it ſtands at preſent a ſolitary example of this curious genus.

One of the lateſt and moſt ſatisfactory deſcribers of the giraffe is M. Vaillant. The diſcoveries of this ingenious writer, who, in the progreſs of his travels through Africa, had frequent opportunities of ſeeing them in their native haunts, has thrown new light upon their hiſtory. His obſervations are intereſting, and he has, beſides, rendered an important ſervice to ſcience by enriching one or two of the principal muſeums of Europe with ſpecimens of the animal; from whence the naturaliſt is enabled to form his own opinion of this remarkable animal, unbiaſſed by the reports of inattentive obſervers, or the imperfect details of former travellers. A ſpecimen of the giraffe, in excellent preſervation, ſaid to be ſhot by Vaillant, adorns the muſeum of the late Mr. John Hunter in London, from which we may be capable of conceiving no very inadequate idea of the majeſty of this gigantic animal, when ranging at large in the wilds of its native foreſts: even now one cannot contemplate it without aſtoniſhment. "If height alone conſtituted precedency among quadrupeds (obſerves M. Vaillant), the giraffe would undoubtedly claim the firſt rank, meaſuring when full grown near ſeventeen feet from the top of the head to the fore feet." In this paſſage, however, Vaillant ſpeaks only of the male, the female being ſmaller. Sonnini fully confirms the teſtimony of Vaillant in reſpect to the vaſt height of the giraffe, obſerving, that they ſometimes attain to the height of ſeventeen or eighteen feet. Voſmaer goes further, and declares that ſome very reſpectable inhabitants of the Cape of Good Hope aſſured him they had ſeen and killed giraffes, which, including the horns, were 22 Rhinland feet in height, or nearly twenty-three feet of our meaſure. Impartially conſidering, however, all that has been ſaid on this ſubject by writers in general, we may allow fifteen or ſixteen feet to be the common height of this animal.

Thus it appears, admitting the loweſt calculation, that the giraffe is one of the talleſt animals in nature, and every account we have of it tends to prove that it is as ſociable and inoffenſive in its manners as it is beautiful in appearance. Oppian gives a good deſcription of it. "The camelopardalis (ſays this writer) has ſome reſemblance to the camel: it has a ſpotted ſkin like the panther, and a neck as long as the camel; its head and ears are ſmall: its feet broad, and legs long, but the laſt are very unequal, the fore ones being much longer than thoſe behind, which are ſo ſhort, that when the animal is ſtanding it has ſomewhat the appearance of a dog ſeated on its haunches." He alſo ſpeaks of two prominencies upon the head juſt between the ears, which reſemble two ſmall and ſtraight horns, and of the tail being ſhort and tufted at the end, with black hairs. Heliodorus and Strabo both deſcribe it in nearly the ſame manner. Strabo tells us it was called camelopardalis, although it bears no reſemblance to the panther, as the ſkin is not ſpotted in the ſame way; he likewiſe mentions the docility of its diſpoſition, and that it feeds on vegetables. According to Pliny, it was firſt exhibited by Cæſar the dictator in the Circæan games. It was afterwards more frequently introduced. We are told, that in the time of the emperor Gordian, no leſs than ten were ſhewn at once. Aurelian exhibited it, among other remarkable animals, in his triumph on the conqueſt of Palmyra. Heliodorus ſpeaks of its being brought, among other preſents, by the Ethiopian ambaſſadors to Rome. It is repreſented among other rare animals on the Prænestine pavement, made by the direction of Sylla, and is expreſſed both in its grazing and brouſing attitudes.

Among modern writers, the firſt good deſcription of it we meet with is that of Belon. "I have ſeen," ſays he, "an animal in the caſtle of Cairo, which is commonly called *zurnapa*; the Latins anciently ſtiled it camelo-pardalis, a name compounded of leopard and camel, for it is ſprinkled with ſpots like the firſt, and has a long neck like the latter. It is a beautiful molded animal, as gentle as a lamb, and more ſociable than any other wild beaſt. Its head is almoſt like that of the ſtag, excepting its ſize, and it has two ſmall horns on the head, covered with hair: and thoſe of the male are longer than thoſe of the female." Its neck, he further tells us, is long, ſtraight, and ſlender: its horns round; its legs thin and long, but ſo low behind, that the animal appears as if ſeated. The colour of the hair on the body, he deſcribes, as being white and red. When grazing, it is obliged, he ſays, to ſpread its fore legs very wide, and even then feeds with great difficulty; it is, therefore, he infers, that the giraffe prefers to feed on the leaves of trees rather than to graze in the fields, eſpecially as its neck is exceedingly long, and can reach to a great height.

The deſcription Gellius affords us of the giraffe is ſtill more ſatisfactory. This writer ſaw three camelopards at Cairo, which he thus deſcribes: on their heads are two horns ſix inches long, and in the middle of their forehead a tubercle riſes to the height of about two inches, which appears like a third horn. This animal is ſixteen feet high when it holds up its head. Its neck alone is ſeven feet, and it is twenty-two feet long from the tip of the noſe to the end of the tail; its fore legs are nearly of an equal height, but the thighs before are ſo long in compariſon to thoſe behind, that its back inclines like the roof of a houſe. Its whole body is ſprinkled with large yellow ſpots, which are nearly of a ſquare form. Its feet are cloven like the ox; its upper lip hangs over the under; its tail is ſlender, with hair on it to the very point: it ruminates like the ox, and, like that animal, feeds upon herbage: its mane extends from the top of the head to the back. When it walks, it ſeems as if both ſides were alternately lame, and when it grazes, or drinks, it is obliged to ſpread its fore legs prodigiouſly wide." This laſt paſſage in Gellius's account is contradicted by Vaillant, who aſſerts, it can even drink from a river the ſurface of which is lower than the bank on which it ſtands; and this account of Vaillant, M. Voſmaer (formerly director of the ſtadtholder's collection of natural hiſtory) obſerves, is confirmed by conſidering the ſtructure of the neck, the vertebræ of which are connected with thoſe of the back by a ſtrong ligament.

Antonius Conſtantius, a writer of the fifteenth century, gives an account of a giraffe he ſaw at Faro, which he ſays was ſo gentle that it would eat bread, hay, or fruit, out of the hand of a child, and that when led through the ſtreets, it would take whatever food of this kind was offered to it by the ſpectators. Vaillant confirms this character of the giraffe: he ſays it is of a mild and harmleſs diſpoſition, and when attacked endeavours merely to ſave itſelf by flight, running, according to this writer, with great ſwiftneſs, though in a ſomewhat peculiar and awkward ſtyle, on account of the length of its neck, and breadth of its fore parts, compared with the hind. Vaillant chaſed one of theſe animals on full ſpeed on horſeback, but the animal on turning a ſmall hill, was ſoon out of ſight; the dogs, however, came up with him, and he was obliged to ſtop and defend himſelf, which he endeavoured to do by kicking in a forcible manner, and Vaillant was ſo fortunate as to kill the animal at a ſingle ſhot. Mr. Gordon relates, that a giraffe which he had wounded, ſuffered him to approach it as it lay on the ground, without offering to ſtrike with its horns, or ſhewing any inclination to revenge itſelf: he even ſtroked it over its eyes ſeveral times, when it only cloſed them, without any ſigns of reſentment. Its throat was afterwards cut for the ſake of its ſkin, and when in the pangs of death it ſtruck the ground with its feet, with a force much exceeding that of any other animal; and theſe ſeem to be its principal means of defence.

The male and female giraffe reſemble each other when young, but as the animal advances in age, the ſpots on the male become dark-brown, while thoſe of the female continue of a ferruginous caſt: the latter is, however, ſaid to acquire the duſky ſhades of the male when very old. The tubercle on the forehead, which occurs in both ſexes, is ſmaller on that of the female than the male, and the female has alſo four teats as in the cow. According to Vaillant, the teeth in the giraffe, thirty-two in number, are ſituated thus: ſix grinders on each ſide, both above and below: no front teeth in the upper jaw, but eight in the lower. The horns, both from their ſize and form, ſays M, Voſmaer, ſeem intended merely for ornament: they appear to be excreſcences of the os frontis. Theſe conſiſt of a porous bony ſubſtance, covered externally with ſhort coarſe briſtly hair: they terminate abruptly in a flattiſh or ſlightly convex head, but little wider than the other parts of the horn, and are edged with ſtiff briſtles all round the outline. The hoofs are moderately large and black. All the accounts we have of the giraffe agree in repreſenting its hind quarters as about two feet and a half lower than its withers; but from obſervations made by profeſſor Camper on the complete ſkeleton of the animal formerly in the collection of the prince of Orange, it would appear, that naturaliſts have been miſtaken in this particular. That its fore legs are longer than its hinder legs is true; but the difference is not more than ſeven inches, which, in a height of ſeven feet, is of ſmall conſequence. It may, however, be rendered apparently more conſiderable by the obliquity of the thigh bone with reſpect to the tibia, when compared with that of the humerus to the radius.

The giraffe is chiefly a native of Ethiopia, but there are other parts of Africa, and of Aſia likewiſe, which this intereſting animal inhabits. At the Cape of Good Hope they ſeem to be not very uncommon. They are alſo found as far in the interior of Africa as Senegal, but not, as ſome ſay, in Guinea, or any of the weſtern parts, nor very far to the ſouthward. Theſe animals are ſometimes ſeen in ſmall groupes to the amount of ſix or ſeven together, and when diſturbed, run off with great celerity. They are principally found in foreſts living on herbage of various kinds, but chiefly on the foliage of trees: there is a ſpecies of mimoſa, in particular, which the natives of the Cape call *kannap*, and the Dutch coloniſts, *kameel-doorn*, which the giraffe is remarkably fond of. The Hottentots affirm, that the female goes twelve months with young, and has never more than one foal at a time. The fleſh they deem excellent, and often hunt and kill them for the ſake of food, and for the ſkin of the animal, the latter of which forms a thick and durable kind of leather. In Arabia, the giraffe is known by the name of *ſirapha*, and *zurnaba*, or *zurnapa*.

CAMELOPARDALUS, in *Aſtronomy*, a new conſtellation of the northern hemiſphere, formed by Hevelius, conſiſting of 32 ſtars firſt obſerved by him, ſituate between Cepheus, Caſſiopeia, Perſeus, the two Bears, and Draco, and containing 58 ſtars in the Britiſh Catalogue.

CAMELUS, in *Entomology*, a German ſpecies of SCARABÆUS, deſcribed by Olivier and Fabricius; the thorax of which is four horned; ſhield ſomewhat bicornuted behind; body black. Obſ. The female has a double tranſverſe carinated line on the ſcutel, the poſterior one of which is largeſt.

CAMELUS, in *Ornithology*, *Struthio Camelus*, the black, or common oſtrich. This is ſpecifically diſtinguiſhed from the other ſpecies of STRUTHIO, by having only two toes to each foot. Linn. &c.

The oſtrich is, without doubt, ſays Dr. Latham, the largeſt bird in the creation; it is near eight feet in length, and, when ſtanding upright, is from ſix to eight feet in height. A ſpecimen of this bird, nearly as large, is preſerved in the Leverian muſeum. We have alſo ſeen in the menagery, at Exeter Change, a living oſtrich rather larger. Two oſtriches were ſhewn in London in the year 1750, the male of which, it is recorded in the Gentleman's Magazine, was ten feet in height, and weighed three hundred weight and one quarter. This laſt is the largeſt bird of the kind we ever heard of. The oſtrich has a ſmall head not much unlike that of a gooſe; the bill is alſo ſomewhat ſimilar, but leſs depreſſed, and four inches and a half in length, horn colour, with the tip duſky. The irides are hazel; eye-lids beſet with hairs; the head, and greateſt part of the neck, are bare of feathers, and of a fleſh colour, with a few ſcattered hairs. Lower parts of the neck and body are covered with black feathers, which are ſingularly looſe in their webs, and totally unlike thoſe of any other bird; the quill-feathers, and thoſe of the tail, are ſnowy white, long, and beautifully waved, with the tips of ſome few of them black. On each wing are two ſpurs about an inch in length, and on the breaſt is a callous, bare, and hard ſubſtance, ſerving the bird to reſt on when it firſt bends forward to ſit on the ground: thighs and ſides of the body naked: legs ſtrong, greyiſh brown, and furniſhed with two claws, the outer one of which is very ſhort, and without a claw. The female differs in having thoſe feathers brown, which in the male are black.

This bird inhabits Africa, and thoſe parts of Aſia that lie contiguous to it, but appears to be moſt abundant about the Cape of Good Hope. The egg is as large as a child's head; and capable of containing better than five pints of liquor. The female is ſuppoſed to lay nearly fifty eggs in a ſeaſon; from ſixteen to twenty is the amount of thoſe uſually contained in a ſingle neſt, according to Dr. Sparrman. Theſe the female oſtrich buries in the ſand, where, it is the common opinion, they are hatched by the heat of the ſun, the female taking no further care of them after once depoſiting them in ſafety; but this is contradicted, in a great meaſure, both by Kolben and Sparrman. Kolben tells us the male and female ſit on them by turns, and that he has ſeen them hatching their eggs hundreds of times, and as often driven them off, and taken their eggs to feaſt himſelf and his friends; one of which would prove a meal for three or four perſons; and beſides this, they are ſaid to be very good. Dr. Sparrman thinks, the male and female ſit on the eggs by turns, as in one of his journies, in the month of December, he frightened a male from the neſt, which was made only on the bare ſand, on which the eggs lay ſcattered and looſe, and were eleven in number. Buffon allows, that the oſtrich ſcarcely ever loſes ſight of the eggs, but aſſerts, that it is only in the more northern parts that the female has occaſion to ſit on them, the ſun being alone ſufficient to hatch them in the torrid zone. Kolben ſays, the young ones cannot run when firſt hatched, but are ſupplied with graſs and water by the old ones. The adult birds are endowed with great ſtrength.

Oſtriches feed on vegetables, and beſides which they are frequently obſerved to ſwallow various other ſubſtances. Old nails, and other bits of iron, lead, copper, or glaſs, are alike indiſcriminately taken into the ſtomach of this voracious bird. It is a vulgar notion, however, that the oſtrich can eat ſuch ſubſtances; that they ſwallow them is clear, but it would be the height of abſurdity to imagine they can digeſt them; nor do they always ſwallow them with impunity, as they are liable to many accidents, from their promiſcuous manner of feeding, and the ſwallowing of iron and other ſuch ſubſtances ſometimes proves fatal to them.

The natives of thoſe parts which the oſtrich inhabits moſt commonly take them by hunting. They follow the birds at a diſtance for two or three days, when the birds, fatigued by being perpetually haraſſed, and wanting time to take food, are very eaſily overtaken, and killed with their clubs. Other oſtrich hunters conceal themſelves in the ſkin of one of thoſe birds, and by that means approach near enough to ſurpriſe them. It is alſo uſual to hunt them on horſeback with dogs, and after overtaking them to approach ſo cloſe as to apply the hooked end of a ſtaff round their legs, which throwing them down they may be either taken alive, or knocked on the head immediately.

The capture of theſe birds is an object of conſequence to the Africans. Oſtrich feathers are in requeſt for ornamental purpoſes in all parts of the world, and form an article of commerce between the Africans and European powers. The ſkin of this bird is very thick, and being of a durable nature is a good ſubſtitute for leather. The fleſh is eaten by the Hottentots, and the eggs are in eſteem both with the Africans and European ſettlers. The egg-ſhells anſwer for drinking cups and other utenſils, and are often mounted in gold or ſilver for that purpoſe. They are hard and durable, and, when fine, are not greatly inferior to ivory. In the

Eaſt both the ſhell of this bird, and that of the caſſowary, are adminiſtered as medicine.

CAMELUS, or *Camel*, in *Zoology*, a genus of quadrupeds, which, in the Linnæan ſyſtem of animals, ſtands in the PECORA order of his claſs MAMMALIA. The character of this genus conſiſts in having no horns: the front teeth in the lower jaw ſix, rather thin, and broad: laniarii or canine teeth diſtant, three in the upper jaw, and in the lower two: upper lip cleft or divided.

Zoologiſts diſcriminate ſeveral ſpecies of the camel tribe, independently of thoſe animals which are known in Europe by the appellation of the Arabian camel, or dromedary, and the Bactrian camel. Gmelin ſpeaks of five, making altogether, with the two preceding, ſeven ſpecies, namely, *Camelus dromedarius* of Linnæus, the common, or Arabian camel: *Camelus bactrianus*, Linn. the bactrian camel: *Camelus glama*, the llama, or lama: *Camelus huanacus*, the guanaco, huanaco, or allo-camelus of Geſner: *Camelus araucanus*, the chilihueque, or Peruvian ſheep of ſome authors: *Camelus vicugna*, the vicuna; and *Camelus paco*, the paco, or pacos of Pennant.

The firſt ſpecies, *Camelus dromedarius*, is diſtinguiſhed by having only one bunch, or protuberance, on the back. The general height of this camel, meaſured from the top of the dorſal bunch to the ground, is about ſix feet and a half, but from the top of the head when the animal elevates it not much leſs than nine feet: the head, however, is uſually ſo carried as to be nearly on a level with the bunch, or rather below it, the animal bending the neck extremely in its general poſture: the head is ſmall; the neck very long; the body of a long and meagre ſhape: the legs rather ſlender, and the tail, which is ſlightly tufted at the extremity, reaches to the joints of the hind legs: the feet are very large, and are hoofed in a peculiar manner, being divided above into two lobes, not reaching through the whole length of the foot; and the extremity of each lobe is guarded by a ſmall hoof: the under part of the foot is covered with an extremely ſtrong, tough, and pliable ſkin, which, by yielding in all directions, enables the animal to travel with peculiar eaſe and ſecurity over dry, hot, ſtony, and ſandy regions, which would ſoon parch and deſtroy the hoof. On the legs are ſix calloſities, viz. one on each knee; one on the inſide of each fore leg, on the upper joint, and one on the inſide of each hind leg, at the bottom of the thigh. On the lower part of the breaſt is alſo a large callus or tough tubercle, which is gradually increaſed by the conſtant habit which the animal has of reſting upon it in lying down.

One cannot be deceived as to the native country of the camel, ſays the energetic Buffon, when we conſider the nature and ſtructure of theſe animals; they are the natural inhabitants of the burning deſerts of Arabia, from whence they have been gradually diffuſed over the reſt of Africa and Aſia. It has been tried, but without effect, to multiply camels in Spain; they have alſo in vain been tranſported to America, but they have ſucceeded neither in one climate nor in the other, and they are ſeldom to be met with in the Eaſt Indies beyond Surat and Ormus. It is not abſolutely to be ſaid, that they cannot ſubſiſt and increaſe in the Eaſt Indies, Spain, America, or even in colder countries in Europe, by keeping them during winter in warm ſtables, feeding, and treating them with care; not allowing them to labour, or ſuffering them to walk out but when the weather is fine, they may be kept alive, and we might even hope to ſee them multiply, but their offspring will be neceſſarily ſmall and languid. They loſe, therefore, all their value under the influence of our climates, and inſtead of becoming uſeful, the rearing of them is attended with much fruitleſs expence; while on the contrary, in their native country, they may be ſaid to compoſe all the wealth of their maſters. Camels have conſtituted the riches of Arabia from the earlieſt ages of the world: the modern Arabs eſtimate their wealth by the number of theſe uſeful animals.

The camel is venerated by the Arabs as the gift of Heaven, as a ſacred animal, without whoſe aid they could neither ſubſiſt, trade, nor travel. They alſo eat its fleſh, eſpecially that of the young camel, which they reckon excellent. The hair of theſe animals, which is fine and ſoft, and is renewed every year, ſerves them to make ſtuffs for their cloathing and furniture. Bleſt with their camels, they not only want for nothing, but they fear nothing. In a ſingle day they can traverſe a tract of fifty leagues into the deſert, and thus eſcape the reach of their enemies. All the armies in the world, ſays Buffon, would periſh in the purſuit of a troop of Arabs: figure to yourſelf, for inſtance, obſerves this writer, a country without verdure, and without water, a burning ſun, an air always clear, plains of ſands, and mountains ſtill more parched, over which the eye extends without perceiving a ſingle animated being; a dead earth perpetually toſſed by the winds, preſenting nothing but bones, ſcattered flints, rocks perpendicular or overthrown; a naked deſert where the traveller never breathes under a friendly ſhade, where nothing accompanies him, and where nothing recals to mind the idea of animated nature; an abſolute ſolitude, infinitely more frightful than that of the deepeſt foreſt; for to man trees are, at leaſt, viſible objects; more ſolitary and naked, more loſt in an unbounded void, he every where beholds the extended ſpace ſurrounding him as a tomb: the light of the day more diſmal than the darkneſs of night, ſerves only to give him a clearer idea of his own wretchedneſs and impotence, and to preſent before his eyes the horror of his ſituation, by extending round him the immenſe abyſs which ſeparates him from the habitable parts of the earth; an abyſs which in vain he would attempt to traverſe, for hunger, thirſt, and burning heat haunt him every moment that remains between deſpair and death. The Arab, nevertheleſs, by the aſſiſtance of his camel, has learned to ſurmount, and even to appropriate theſe frightful intervals of nature to himſelf. They ſerve him for an aſylum, they ſecure his repoſe, and maintain his independence. But man never uſes any thing without abuſe. This ſame free, independent, tranquil, and even rich Arab, inſtead of regarding his deſerts as the ramparts of his liberty, pollutes them with his crimes. He traverſes them to carry off gold and ſlaves from the adjacent nations. He employs them for perpetrating his robberies, which unfortunately he enjoys more than his liberty. An Arab, who deſtines himſelf to this kind of piracy, is early accuſtomed to the fatigues of travelling, to want of ſleep, and to endure hunger, thirſt, and heat. With this view he inſtructs, rears, and exerciſes his camels. A few days after their birth, he folds their limbs to remain on the ground, and in this ſituation he loads them with a pretty heavy weight, which is never removed but for the purpoſe of replacing a greater. Inſtead of allowing them to feed at pleaſure, and to drink when they are thirſty, he regulates their repaſts, and makes them gradually travel long journies, diminiſhing at the ſame time their quantity of food. When they acquire ſome ſtrength, he exerciſes them to the courſe; he excites their emulation by the example of horſes, and in time renders them equally ſwift and more robuſt. At length, when he is aſſured of the ſtrength, fleetneſs, and ſobriety of his camels, he loads them with whatever is neceſſary for his and their ſubſiſtence, departs with them, arrives unexpectedly at the confines of the deſert, robs the firſt paſſenger he meets, pillages the ſtraggling habitations,

tions, loads his camels with the booty, and if purſued is obliged to accelerate his retreat. It is on theſe occaſions that he unfolds his own talents and thoſe of his camels: he mounts one of the fleeteſt, and conducting the troop, makes them travel night and day, almoſt without ſtopping either to eat or drink; and in this manner he eaſily paſſes over the ſpace of three hundred leagues in eight days. During all that time of fatigue and travel he never unloads his camels, and only allows them an hour of repoſe, and a ball of paſte each day. They often run in this manner for eight or nine days, without meeting with any water, and when by chance there is a pool at ſome diſtance they ſcent the water, even when half a league from it. Thirſt makes them redouble their pace, and they drink as much at once as ſerves them for the time that is paſt, and for as much to come, for their journey often laſts them ſeveral weeks, and their abſtinence continues till their journey be accompliſhed.

Throughout Turkey, Perſia, Egypt, Arabia, Barbary, and various other contiguous countries, all kinds of merchandize are carried by camels, which of all conveyances is the moſt expeditious, and attended with the leaſt expence. Merchants and other travellers aſſemble, and unite in caravans to avoid the inſults and robberies of the Arabs. Theſe caravans are often numerous, and are always compoſed of more camels than men. Each camel is loaded according to his ſtrength, and when overloaded he refuſes to proceed, remaining in his reſting poſture till his burden is lightened. Large camels generally carry from a thouſand to twelve hundred pounds weight, and the ſmalleſt from ſix to ſeven hundred. In theſe commercial travels their march is not haſtened; as the route is often ſeven or eight hundred leagues, their motions and journies are regulated. They walk only, proceeding at the average rate of ten or twelve leagues each day. Camels that form a part of theſe mercantile caravans, unlike thoſe of the predatory Arabs, it is affirmed, are relieved from their load every night, and allowed to feed at liberty; and in a country where they find abundant paſture they eat in one hour ſufficient to ruminate for a whole night, and to nouriſh them for twenty-four hours. But it is ſeldom they meet with ſuch paſturage; neither is this delicate food neceſſary for them. They even ſeem to prefer wormwood, thiſtles, nettles, furze, and other prickly and thorny vegetables to the ſofteſt herbs, and ſo long as they can find herbage they can eaſily diſpenſe with drink. With qualities of ſuch general utility, in paſſing over the dreary regions of the deſerts theſe valuable animals poſſeſs no ordinary ſhare of ſagacity. They are ſaid, indeed, to be extremely ſenſible of injuſtice and ill-treatment. The Arabs aſſert, that if a perſon ſtrike them without cauſe, he will not find it eaſy to eſcape their vengeance, and that they will retain the remembrance of it till an opportunity offers for gratifying their revenge, having in this point a ſtriking ſimilarity of character with their Arab maſters. It is ſaid, that in their fits of rage they ſometimes take up a man in their teeth, throw him on the ground, and trample him under their feet. Eager of revenge, they retain, however, no longer any rancour, when once they are ſatisfied, and it is even ſufficient if they believe they have gratified their revenge. Accordingly we are told the crafty Arab, when he has by chance excited the rage of a camel, will lay down his garments in ſome place near which the animal muſt paſs, and diſpoſe them in ſuch a manner, that they appear to cover a man ſleeping under them. The camel knows the garments of him by whom he has been treated with injuſtice, ſeizes them with his teeth, ſhakes them violently, and tramples on them in a rage. When his anger is appeaſed by this means, he leaves them, and then the owner of the dreſs may make his appearance without fear, and load and guide, wherever he pleaſes, the animal, who ſubmits with aſtoniſhing docility to the will of a man, whom juſt before it was his wiſh to deſtroy. "I have ſometimes ſeen *hadjins*, or dromedaries, in Upper Egypt, (writes Sonnini,) weary of the impatience of their riders, ſtop ſhort, turn round their long neck to bite them, and utter cries of rage. In theſe circumſtances the rider muſt be careful not to alight, as he would infallibly be torn to pieces; he muſt alſo refrain from ſtriking his beaſt, which would only increaſe his fury. Nothing can be done but to have patience, and appeaſe the animal by patting him with the hand, which frequently requires ſome time, when he will reſume his way and his pace of himſelf. The pace of theſe dromedaries is a very long trot, during which they carry the head high, and the tail ſtretched out ſtiff in a horizontal poſition." The ſaddle, or rather pack-ſaddle, on which the rider ſits, Sonnini deſcribes as being hollowed in the middle, and having at each ſaddle-bow a round piece of wood, placed vertically, which he graſps firmly with each hand to keep himſelf in his ſeat. Some of the ſaddles are more ſimple, not ſo well ſtuffed, and leſs commodious than thoſe of the Arabs, and the handles of the ſaddle-bows are horizontal. Theſe are brought from Sennaar, the capital of Nubia. A long pocket ſuſpended on each ſide to hold proviſions for the rider and his beaſt; a ſkin of water for the rider alone, as the dromedary can travel a week without drinking, with a leather thong in the hand to ſerve as a whip, are the whole of the traveller's equipage: and thus equipped he may croſs the deſerts, travelling fifty, or even fourſcore leagues a day! if this writer can be relied upon. This mode of travelling is fatiguing to exceſs; the loins are broken by the rough and quick ſhaking of the dromedary's pace; the hands are ſoon galled, and become painful; and the burning air which you divide with rapidity impedes the breath, ſo as almoſt to induce ſuffocation. The moſt extraordinary journey of this kind Sonnini ever heard mentioned, was made by a Bedouin, who was pointed out to him at Cairo. He had travelled from that city to Mecca, a diſtance of more than 400 leagues, in five days, a journey for which the caravan of pilgrims employ upwards of thirty days. When the traveller is not in haſte, or accompanies a caravan, the progreſs of which is always ſlow on account of the camels of burden, a kind of covered litter is fixed on one of theſe animals for his accommodation, in which he is tolerably at his eaſe, and may even ſleep if ſo diſpoſed. Women uſually travel in this manner, ſometimes five or ſix together in a litter.

The ancients believed that the dromedary had a natural antipathy to horſes. Xenophon aſſerts this; and Pliny repeats it on the credit of Xenophon. Others have ſaid that they entertain an equal averſion for aſſes and mules. But the truth appears to be preciſely the contrary; for all theſe animals, at leaſt in Egypt and Turkey, live and travel together. Sonnini affirms that there is always an aſs at the head of a file of loaded camels, to whom he officiates as leader, the firſt of the camels being faſtened to the aſs, and following him ſtep by ſtep. Others have agreed in the aſſertion that camels muſt not be beaten too much, or on improper occaſions, which would ſoon make them turn reſtive; but the drivers of the loaded camels have a ſtick with which they beat them, and they who ride upon camels, whip them with a long ſtrap of leather. They are alſo urged on with a clicking of the tongue, much like that employed by us in Europe to inſpirit our horſes It is proper likewiſe to remark, while on this ſubject, that the Bedouins never whiſtle, and that it gives them pain if a traveller, ignorant of their cuſtoms, ſhould whiſtle in their company. Sonnini is perſuaded that even when the Arabs ſing on their march, their object is not to encourage the camels to proceed, but to beguile the tediouſneſs of their journey. Should this opinion be founded in fact, it muſt entirely deſtroy the veracity of Buffon, and ſeveral other writers, who tell us the camels in their march require neither the ſpur nor whip, but when they begin to be tired their courage is ſupported, or rather their fatigue is charmed, by ſinging or by the ſound of ſome inſtrument. Their conductors, we have been told by travellers, relieve each other in ſinging; and when they want to prolong the journey, they give the animals but an hour's reſt; after which, reſuming their ſong, they proceed on their march for ſeveral hours more, and continue to ſing till they arrive at the next reſting place.

The mode of the camel's walk, as deſcribed by Ariſtotle (Hiſt. Anim. lib. ii. cap. i. p. 480. Caſaubon. Lugdun. 1590.) is by raiſing the two legs of the ſame ſide, the one immediately after the other; not moving the legs diagonally, in the manner of moſt other quadrupeds. When he accelerates his pace, it is in the ſame manner as a horſe ambles; though to the rider ten times more jolting than the hardeſt trot of a horſe. M. Niebuhr informs us, in his "Travels through Arabia, &c." that he meaſured the diſtances of places, by counting the ſteps of the camel, and comparing the number with the time in which they were travelled by his watch. In the Philoſophical Tranſactions (vol. lxxxi. part. 2. for 1791) we have an ingenious Memoir "On the rate of travelling, as performed by camels, and its application, as a ſcale, to the purpoſes of geography," by James Rennell, eſq. He obſerves, that the rate of the camel's movement appears to him to be, beyond all others, the leaſt variable, whether we examine it by portions of days or of hours. Accordingly he examined five journals of gentlemen who had croſſed the deſerts between Aleppo, Bagdad, and Baſſorah; viz. that of Mr. Carmichael, in 1751, that of colonel Capper in 1778, that of Mr. Hunter, in 1767, that of Mr. Holford, in 1780, and that of Mr. Irwin, in 1784; and after comparing in various ways the data which theſe journals afford, he concludes, that the hourly rate at which a camel travels, as deduced from Mr. Carmichael's journey, is 2.475 Britiſh miles; from col. Capper's, 2.51; from Mr. Hunter's, 2.585; from Mr. Irwin's, 2.48; and from Mr. Holford's, 2.5: and that the mean of the five experiments gives 2.51 Britiſh miles for the rate at which camels travel in an hour; which may therefore be taken at 2½ miles, Britiſh meaſure. Mr. Rennell further remarks, that it does not appear, from theſe journals, that the load of a camel has any influence on its ſpeed, when it is ſuffered to go at its own rate, as it always is in caravans: the only way in which the load affects the camel's travelling is, that the animal will not travel for ſo long a time when fully laden, as it will when light. For the benefit of thoſe, who, in the interior part of Africa, may not be provided with watches, Mr. Rennell, by comparing the number of days in which each of the five journies, as well as one made by Teixera, acroſs the Chaldæan deſert, were performed, with the whole number of hours which elapſed during their journies, has deduced the following circumſtances; viz. that the heavily loaded caravans, which were accompanied by Mr. Carmichael, Mr. Holford, and Teixera, travelled, on a medium, in each day, for $7^{h}\,10'$, $7^{h}\,40'$, and $7^{h}\,30'$, reſpectively; and that the light caravans of Mr. Irwin, Mr. Capper, and Mr. Hunter travelled, in each day, on a medium, for $9^{h}\,12'$, $8^{h}\,38'$, and $8^{h}\,45'$, reſpectively:—the mean of the three former is $7^{h}\,27'$, and of the latter $8^{h}\,52'$; conſequently, reckoning the rate of travelling of camels, in caravans, to be 2½ miles in an hour, the diſtance travelled by the heavy caravans, in a mean day, will be 18.625 Britiſh miles, and by the light caravans 22⅙; ſo that hence, any traveller, who is in poſſeſſion of a pocket compaſs, to point out the direction in which he travels, and can tell what that was, and the number of days employed by the caravan in going from one place to another, may contribute, very conſiderably, to the improvement of the eaſtern geography. See CARAVAN.

The facility with which the camels abſtain from drink in their journies over the burning deſerts is more remarkable than their abſtinence from food; and it is ſo extraordinary, that, according to Leo Africanus, they are capable of remaining without drink for 15 days without prejudice to their health; but after long abſtinence, it is ſaid that they are apt, on their firſt meeting with water, to drink ſo greedily that it proves ſuddenly fatal to many of them. This facility does not proceed from habit alone, but is rather, as Buffon obſerves, the effect of their ſtructure. Independently of the four ſtomachs, which are common to ruminating animals, the camel is poſſeſſed of a bag which ſerves him as a reſervoir to retain water. This fifth ſtomach is peculiar to the camel: it is ſo large as to contain a great quantity of water, where it remains without corrupting, or intermixing with other aliments. When the animal is oppreſſed by thirſt, or has occaſion for water to macerate his dry food in ruminating, he cauſes part of the water to aſcend into his ſtomach, or even as high as the throat, by the mere contraction of certain muſcles. It is by virtue of this conformation that the camel is enabled to paſs ſeveral days without drinking, and to take at any one time a prodigious quantity of water, which remains in the reſervoir pure and limpid, becauſe neither the liquors of the body nor the juices of digeſtion can mix with it. There can be no doubt that the water preſerved by the camel in this receptacle remains perfectly pure, all writers agreeing in this particular; it is no very uncommon circumſtance in paſſing through the deſerts for travellers to kill a camel in order to obtain a ſupply of water from this receptacle when they are deſtitute of this neceſſary article, and cannot procure it in any other manner. The loſs of a camel, on ſuch an occaſion, is of the leſs conſideration, as the fleſh affords the traveller and Arabs a rich repaſt, independent of the advantage of being ſupplied with water; inſtances of this occur in Bruce's travels to diſcover the ſource of the Nile, and various others

That water, in caſes of emergency, is taken from the ſtomach of the camel, is a fact neither doubted in Syria, nor thought ſtrange. In proof of this fact, it is hardly neceſſary to allege the teſtimony of an Arab hiſtorian (Beidawi) who, in his account of the prophet's expedition to Tabuc againſt the Greeks, relates, among other diſtreſſes of the army, that they were reduced to the neceſſity of killing their camels for the ſake of the water contained in their ſtomachs. Sale's Koran, p. 164. Gibbon's Decl. of the Rom. Emp. vol. v. p. 245. However, Mr. John Hunter, who diſſected a camel, ſaw no reaſon for aſſigning more than four ſtomachs to this animal; though he could conceive that water might be found in the paunch little impregnated by the dry provender of the deſert, and readily ſeparating or draining from it. Mr. Home alſo, who aſſiſted at the diſſection, and who prepared the different ſtomachs in a dry ſtate for the purpoſe of ſhewing their internal ſtructure, and communication with one another, inferred, from this preparation, that the number of ſtomachs is four, as in other ruminating animals; ſo that it cannot be ſaid that there is a diſtinct reſervoir for water: but the ſecond ſtomach has a very peculiar ſtructure, being made up of numerous cells, ſeveral inches deep, with their mouths uppermoſt, and orifices apparently capable of muſcular contraction. When the animal drinks, ſays Mr. Home, it probably has a power of directing the water into theſe cells, inſtead of letting it paſs into the firſt ſtomach, and when theſe are filled, the reſt of the water will go into the firſt ſtomach. In this manner a quantity of water may be kept ſeparate from the food, ſerving occaſionally to moiſten it in the paſſage to the fourth or true ſtomach. The teſtimony of travellers to water being found in the ſtomach, and Daubenton, upon diſſection, meeting with it in the ſecond ſtomach, when compared with the ſtructure of the parts, ſeem to confirm the above conjecture. See Ruſſell's Nat. Hiſt. of Aleppo, vol. ii. p. 426.

If we reflect on the diſſimilarity of this animal to other quadrupeds, Buffon conceives that we cannot doubt but his nature has been conſiderably changed by conſtraint, ſlavery, and perpetual labour. Of all animals, ſays he, the camel is the moſt ancient, the completeſt and moſt laborious ſlave. He is the moſt ancient ſlave, becauſe he inhabits thoſe climates where men were firſt poliſhed. He is the moſt complete ſlave, becauſe in the other ſpecies of domeſtic animals, as the horſe, the dog, the ox, the ſheep, the hog, &c. we ſtill find individuals in a ſtate of nature, and which have not ſubmitted to man. But the whole ſpecies of the camel is enſlaved, for none of them exiſt in their primitive ſtate of liberty and independence. Laſtly, he is the moſt laborious ſlave, becauſe he has never been nouriſhed for pomp like moſt horſes, nor for amuſement like moſt dogs, nor for the uſe of the table like the ox, the hog, and the ſheep; becauſe he has always been made a beaſt of burden, whom men have never taken the trouble of harneſſing or yoking in machines, but have regarded the body of the animal as a living carriage, which they may load or overload even during ſleep, for when preſſed, the load is ſometimes not taken off, but the animal lies down under it with his legs folded, and his body reſting on his ſtomach. Buffon expatiates in this paſſage with conſiderable animation on the ſeverity of the ſervitude to which this uſeful animal is condemned, but the degraded picture he has drawn, it muſt be allowed, admits of ſome alleviation. It is not in all countries it inhabits that the camel is dealt thus rigorouſly with; there are many parts in which he is held in greater favour, and treated with more indulgence than this lively writer intimates. That the camel is kept for pomp as well as utility in various parts of Aſia and Africa, is certain. Many authors ſpeak to this effect. Mr. Bruce frequently ſaw them ſaddled and harneſſed in Africa. Sonnini ſpeaks of them as highly uſeful for the ſaddle. In the eaſt they are oftentimes richly capariſoned for the ſervice of the great. In China, a particular breed of them is trained like our race-horſes for the courſe, and for the performance of journies that require expedition. Camels are alſo inſtructed ſometimes for warlike purpoſes. Mr. Bruce deſcribes the arrival of the caravan from Syene eſcorted by 400 Ababdé, or fighting men, all upon their camels, each armed with ſhort javelins. The manner of their riding he thought more whimſical than calculated to inſpire terror; there were two ſmall ſaddles on each camel, one ſuſpended on each ſide of the animal, ſo that the two ababdé on each camel ſat back to back, a mode which in their practice of fighting he allows may be convenient enough, but had they ventured to contend with the European travellers every ball might have killed two inſtead of one. The camels, however trained by the Egyptians for war and for the ſaddle, were found of conſiderable ſervice in the French armies for the uſe of their diſmounted cavalry, when they lately invaded Egypt. So far, indeed, from the camel being always treated with the rigour Buffon deſcribes, and never being harneſſed or yoked in machines, as he affirms, the teſtimony of every traveller contradicts it. We know that in Tartary the camel is regarded with as much, if not more attention than the horſe. Opulent Tartars, according to Pallas, take a pride in conveying their families from place to place, or in travelling to town in covered waggons drawn by camels; the yoke is placed between their neck and the firſt dorſal bunch (for it is a variety of the Bactrian camel they poſſeſs), and is of a peculiar conſtruction adapted for the purpoſe. Theſe are ſeldom uſed as beaſts of burthen, but are often yoked to the large four-wheeled waggons or *Madſhari*, eſpecially on bad roads and during winter. In armies Pallas conceives they would be ſerviceable both as beaſts of burthen, and in putting to flight any cavalry, the horſes of which are unaccuſtomed to the ſight of theſe curious animals. And indeed the Ruſſians begin to be aware of the value of the camel for the purpoſes of war. In the year 1796 no leſs than a thouſand camels were bought up in Crim Tartary for the uſe of the army in Perſia. In Ruſſia the price of a full grown camel is generally from 100 to 150 roubles, or from 22l. 10s. to 33l. 15s. ſterling. The Egyptians keep large numbers of camels, which are bred and ſold by them to the Arabs. They fetch a pretty high price. At Cairo, according to Sonnini, they are worth 4 or 500 livres each, which is about the loweſt average price they bear in Ruſſia. But in Upper Egypt they are not ſo dear; their price varying from 2 to 300 livres. They are equally numerous in Barbary, but they become more ſcarce towards the weſtern coaſts of Africa. Among other hardſhips endured by the camel, Buffon complains, that it is never nouriſhed for the table like the ox, the hog, or the ſheep; another aſſertion by no means well founded: when by miſchance they have met with any accident that is likely to incapacitate them for the burthen, they are commonly fattened and killed for this purpoſe. We frequently hear of the lame camels being butchered for uſe. Mr. Bruce and his party were frequently regaled with a comfortable meal of camel's fleſh ſtewed, and he ſpeaks of it as an ordinary circumſtance on any occaſion of feaſting or rejoicing in Africa to kill a young camel, and ſerve it up to table. The Jews diſſeminated over the eaſtern, or African parts of the world, do not eat the fleſh of the camel, becauſe they are expreſsly forbidden by the Moſaic laws (Levit. chap. xi. ver. 4.), but the Arabs, and the other inhabitants of Egypt, &c. with the exception of the Chriſtians, conſider it as a dainty and wholeſome food. A curious circumſtance is mentioned by Sonnini reſpecting this: in thoſe cities, he tells us, where the fanaticiſm of the Mahometans is at the higheſt pitch, as in Cairo and Alexandria, it would be deemed a profanation to ſell the fleſh of the camel to the Franks, who, however, on their part, are by no means deſirous of it, for, though it has no diſagreeable flavour, it is hard and dry. In Barbary camels' tongues are ſalted and ſmoked for exportation to Italy, and other countries, and theſe form a very good diſh.

Beſides the highly beneficial properties of the camel for the ſaddle, as a beaſt of burthen, for the yoke, and as wholeſome food, the camel poſſeſſes others not leſs valuable. Its hair is an important article of commerce, and ſerves likewiſe for the fabrication of the tents and carpets of the Arabs, and for wearing apparel: rich ſhawls are made of the hair of camels that are in much requeſt. The Tartar women manufacture a narrow ſort of cloth of it which is uſed of its natural colour: a broad cloth is, or at leaſt was formerly produced from the ſame material at the manufactory of *Novoroſſeiſk*, or *Ekaterinoſlavl* in the Crimea. Curious cloths are alſo formed of it in Perſia at this time. It is known by the French in trade, under the improper name of "Laine de Chevron." The moſt eſteemed is brought from Perſia by the caravans of Erivan, Tiflis, Erzerum, and Tocat. There is ſome of three qualities; the black, the red, and the gray. The black is the deareſt; and the gray is worth only half the price of the red. Some of it is brought annually to Marſeilles by way of Aleppo, Smyrna, and Conſtantinople. This laſt city exports from 80 to 100 bales, weighing about 300 pounds the bale. Smyrna and Aleppo ſend a much more conſiderable quantity. This kind of wool is employed in the manufacture of hats; and is purchaſed by all the European nations that trade to the Levant. The French, however, conſume the greateſt quantity of it. The Engliſh employ but a ſmall quantity of the black, which they procure at Smyrna. Olivier's Travels in the Ottoman Empire, p. 223. The dung of the camel is uſed as fuel, and in Arabia the milk of the females affords one of the ſimple and ſalutary aliments of the Bedouins.

The camel that carries Mahomet's ſtandard, which the caravan of pilgrims offer yearly on the tomb of their prophet, is exempted the reſt of its life from all ſervices. It is even pretended that this happy beaſt will riſe again at the general reſurrection, and enjoy the pleaſures of paradiſe.

The general aſpect of the camel, at firſt ſight, is apt to impreſs the mind with the idea of deformity; and in particular the dorſal bunch has the appearance of ſome accidental protuberance rather than a truly natural conformation. This idea ſeems to have operated ſo powerfully on the mind of Buffon, that he has not ſcrupled to advance an opinion that this part, as well as the pectoral bunch, was originally produced from ill uſage in conſtantly loading the animal with heavy burthens, and that having once ariſen, it has been tranſmitted by deſcent, and continues to form a permanent character. In confirmation of this theory, he inſiſts, that although theſe calloſities are to be met with in every camel, yet they plainly prove that they are not natural, but are produced by exceſſive conſtraint and pain, from being often found filled with pus. "The breaſt and legs, therefore, (continues this writer), are deformed by theſe calloſities; the back is alſo disfigured with a ſingle, or double hunch; and both theſe hunches and calloſities are perpetuated by generation. As it is evident the firſt deformity proceeds from the cuſtom of forcing them when quite young to lie on their ſtomachs, with their legs bent under them, and in that cramped poſture to bear not only the weight of their own body, but alſo the burthens which are put upon them, it muſt be preſumed that the hunch, or hunches, owe their origin to the unequal compreſſion of heavy burthens which are put upon them, and have raiſed the fleſh, and puffed up the fat and ſkin; for theſe hunches are not bony, but compoſed of a fleſhy ſubſtance, partly of the ſame conſiſtency as the udder of a cow. Thus the calloſities and the hunches ſhould be equally regarded as deformities produced by the continuance of labour and conſtraint of body; and though at firſt accidental and individual, are now become general and permanent in the whole ſpecies. It may alſo be preſumed that the bag which contains the water, and which is only an appendage to the paunch, has been produced by a forced extenſion of this viſcus. The animal after enduring thirſt for a long time, taking at one time as much and perhaps more water than the ſtomach could contain, this membrane would become extended and dilated, as has been obſerved in the ſtomach of ſheep, which extends and acquires a capacity in proportion to the quantity of its aliment. The ſtomach is very ſmall in ſheep that are fed with grain, while in thoſe that are fed on herbage it becomes very large." "Theſe conjectures, (Buffon allows) however, would be fully confirmed or deſtroyed, if any of theſe animals could be found wild to compare with the domeſtic; but theſe animals do not exiſt any where in a natural ſtate, or if they do, no one has yet remarked or deſcribed them; and we muſt therefore ſuppoſe that all which is good and fair about them they owe to nature, and that which is defective and deformed is occaſioned by the labour and ſlavery impoſed on them by the dominion of man." The Bactrian camel, or that with two dorſal bunches, is, however, ſaid to be found wild in the deſert parts of Aſia between India and China, and to be larger than the domeſticated animal, and ſhould this be true, the reaſoning of Buffon falls to the ground. What he has advanced may apply in ſome meaſure to the calloſities on the legs, or to that on the breaſt, all which may ariſe from the cauſe he aſſigns; but with reſpect to the accidental production of the dorſal protuberance, his conjecture appears improbable. We have every reaſon to believe that thoſe bunches cannot be formed from the ſuperabundance of nouriſhment, although they may be inflated, and appear more plump from this cauſe: thoſe bunches in long journies where they are ſtinted for food, it is ſaid, diminiſh gradually, and are reduced ſo flat at laſt, that their places are only diſcovered by the length of the hair, which is always longer on theſe parts than on the reſt of the back; but the other parts of the body waſte in a ſimilar manner at the ſame time, and when the animals are fattened again, as they acquire fleſh in other parts, thoſe dorſal bunches reſume their former bulk. So that upon the whole we are perſuaded thoſe dorſal bunches are natural both for this reaſon, and becauſe throughout all the varieties of the two moſt frequent kinds of camel, the Arabian and Bactrian, one race is conſtantly diſtinguiſhed by having no more than a ſingle dorſal bunch, and the other two. Were theſe bunches the effect of accident or of heavy preſſure only, we ſhould certainly find nature leſs conſtant in this particular.

The ancients have ſaid that theſe animals are in a condition for generation at the age of three years; but this is doubtful, ſince they have not at that age attained to above half their growth. The young camel ſucks its mother 12 months; and when deſigned for labour, to make him ſtrong and robuſt, they leave him to ſuck or graze for a longer time; nor do they attempt to load him or put him to work till he has attained the age of four years. The camel commonly lives 40 or 50 years, but ſeldom longer. The labouring camels are generally geldings, as they leave but one male for eight or ten females; they are without doubt weaker than the males, but they are more tractable, and ready for employ at all times. The males, on the contrary, are not only ungovernable but even furious in the rutting time, which continues for the ſpace of 40 days, and returns every ſpring. At this ſeaſon they emit frequently a kind of hoarſe lowing, with a ſtrong rattling in the throat; they continually foam, and one or two red veſicles, as large as a hog's bladder, and of a diſguſting appearance, hang out of their mouths. They are extremely dangerous at ſuch times; it is ſaid that in their fits of rage, they will ſometimes take up a man in their teeth, throw him to the ground, and trample him to death. The female goes 12 months with young, and like other large quadrupeds produces but one at a birth.

It is remarkable that the dromedary of which we have been ſpeaking is the only ſort of camel found in Egypt. If we follow the diſtinction made by Ariſtotle and Pliny, and repeated by Buffon, (ſays Sonnini), between two ſpecies of animals which nature has diſcriminated by a conſtant, and very ſtriking mark, there are no camels in Egypt. In fact, there is no animal of that kind which has two bunches on the back (*Camelus Bactrianus, Linn.*); all that are found in this country have only one, and are conſequently of the dromedary ſpecies. The Arabic word *djemmel*, which anſwers to camel, is likewiſe the only one uſed by the inhabitants of Egypt for that breed, which is the moſt common, moſt uſeful, of greateſt ſize and ſtrength, heavy of foot, and employed for carrying burthens. On the contrary, that which is leſs tall and bulky, and poſſeſſed of great agility, is called dromedary by the Europeans, and *hadjin* by the Arabs, becauſe it is the animal which the *hadjis* or pilgrims uſually ride. Sonnini likewiſe mentions a ſmaller kind of camel in Egypt which is much leſs known, and of which he only ſaw a few among the Bedouins; they are of a ſhorter make than the common ſort; their body is more round; they are not ſo tall; their hair is longer and thicker, and they are of a fallow colour inclining to brown.

In concluſion of this article we may adopt the words of Buffon: by uniting under one point of view all the qualities of this animal, and all the advantages which are gained by him, he muſt be acknowledged to be the moſt uſeful of all creatures under ſubordination to man. Gold and ſilk are not the true riches of the Eaſt; the camel is the treaſure of Aſia. He is of greater value than the elephant, as he does as much labour, and does not conſume a twentieth part of the food. Beſides, the whole ſpecies is ſubject to man, who propagates it and multiplies it as much as he pleaſes. But he has no ſuch dominion over the elephant, which he cannot multiply, and the individuals of which he cannot conquer without more trouble and difficulty. The camel is not only of greater value than the elephant, but is perhaps equal in utility to the horſe, the aſs, and the ox, when their powers are united. He carries as much as two mules, though he eats leſs, and feeds on herbs as coarſe as thoſe the aſs will eat. The female furniſhes milk longer than the cow; the fleſh of young camels is as good and as wholeſome as veal: the hair is finer, and in more requeſt than the fineſt wool. Even their excrements are uſeful, for ſal ammoniac is made of their urine; their dung, when dried and powdered, ſerves them for litter, as well as for the horſes with whom they frequently travel in countries where neither hay nor ſtraw is to be obtained. Their dung (chopped and intermixed with ſtraw) forms an excellent fuel, burns freely, gives a clear and nearly as hot a flame as that of dried wood, and which is of great uſe in the deſerts, where not a tree is to be ſeen, and where, for the want of combuſtible materials, fire is as ſcarce as water.

There are ſeveral varieties of this kind of camel differing in ſize, ſtrength, colour, and other ſlight particulars, as in our different breeds of horſes, and other domeſticated animals; and there are likewiſe hybrid varieties produced between this and the following ſpecies. It ſhould be further ſtated, to prevent confuſion, that the dromedarius of Geſner is not the ſame animal as Jonſton deſcribes in his hiſtory of quadrupeds by that name; the latter means the Bactrian, or two bunched camel. Knorr follows this writer, calling the Bactrian camel Dromedar, Trampelthier oder Dromedar; but this, as already ſhewn, is not the true dromedary. Forſkall diſtinguiſhes the Arabian camel, our preſent ſpecies, and dromedary of modern authors, by the title of Camelus vulgaris: it is Camelus of Jonſton; and Camelus Dromas of Geſner.

On medals, the camel is the ſymbol of Arabia, when found on the coins of any other nation. Thus, on a medal of the gens Plautia, we find a woman's head with a mural crown, *A. Plautius Æd. Cur. S. C.* and on the reverſe, *Judæus;* and in the exergue, *Bacchius*; the device, a man on his knees holding with his right hand a camel by the bridle, and with the left, a branch of palm. It alſo denotes alliance with Arabia.

CAMELUS *Bactrianus*, the Bactrian camel, and Le Chameau of Buffon, a ſpecies known from the preceding by having two dorſal bunches. Pallas calls it the Tauridan camel.

This kind attains in the peninſula of the Crimea to a larger ſize than among the Kalmuc Tartars. Pallas obſerved them in that country of a white and yellowiſh white colour, and ſometimes of a blackiſh colour; but theſe laſt were leſs frequent than the others. If we may credit Sonnini, this ſort is not to be found in Egypt, where they alone rear, and cultivate that kind which we denominate the Arabian camel. It is the Tauridan camel that generally prevails in Ruſſia and Siberia; the mild winter of the Crimea in particular is very favourable to the habits and propagation of this animal. This is the camel which authors mention as ſtill exiſting in a ſtate of nature, in the deſerts of the temperate parts of Aſia, more eſpecially in thoſe between China and India, and which is reported to be larger than the domeſticated race. The Arabian camels are beyond compariſon more numerous, and univerſal than this kind, which is chiefly confined to ſome parts of Aſia; a moiſter ſoil and more temperate climate being more congenial to its habits than the hot and parched regions of the African deſerts, which the Arabian camel inhabits. It has acquired the name of Turkiſh camel from being found in Turkeſtan, and ſome other parts of the Levant. From Pallas it may be ſeen that the Tauridan camel is more common in various diſtricts of the Ruſſian territory than is generally conceived. They rarely employ this creature like the Arabian camel as a beaſt of burthen, but train it for the ſaddle, and for drawing travelling waggons, and ſimilar machines in the manner Europeans train horſes. This animal thrives beſt in the milder parts of Tartary; but it bears even the ſeverity of a Siberian climate, being found in the vicinity of the Baikal lake, where we are told the Mongols and Burats keep great numbers of them. Here they are ſaid to live during winter on willows and other trees, a diet affording little nouriſhment, and in conſequence of which they become lean and meagre towards the latter part of the winter ſeaſon. In April they loſe their hair, and go naked all May amidſt the froſts of that ſevere climate. They thrive beſt in dry grounds, and among the ſalt marſhes. This animal is cultivated in China, where they have a breed of peculiar ſwiftneſs, that bears the expreſſive name of *Fong Kyo Fo*, or camels with feet of wind. See the article BACTRIANUS.

CAMELUS *Glama*, the LAMA, is the third ſpecies in the Linnæan genus *camelus*. The modern French naturaliſts conſtitute a diſtinct genus of the lama, camelus glama *Linn.* the huanaco, camelus huanacus, and camelus lama of Erxleben; pernichcatl of Ferdnandez; and guanaco of Ulloa. With thoſe naturaliſts the lama forms the ſecond ſection of ruminating animals, and is characteriſed as having from four to ſix inciſive teeth in the lower jaw; the fiſſure in the upper lip; the length of the neck; and abſence of the dorſal bunches. This diviſion of the *camelus* ſo far as relates to the ſpecies glama is not objectionable: the abſence of the dorſal bunches would form a good generical diſtinction; but in adopting it, we ought certainly to exclude the ſpecies *huanacus*, or guanaco, that animal being remarkable for the gibboſity of the back. It may, however, be better to retain the lama tribe with that of the camelus till we are better acquainted with thoſe animals; for it is not to be diſguiſed that an inexplicable confuſion prevails among writers with regard to ſome of them. They are all natives of South America, and are at beſt but imperfectly known to the naturaliſts of Europe. Even in following the beſt authorities, when treating of them, we are not entirely without ſuſpicion that no great dependence ought to be placed on the characters hitherto aſſigned to ſome of thoſe ſpecies. It is not improbable that ſome of thoſe which are at preſent conſidered as diſtinct ſpecies may hereafter prove to be only varieties of the reſt.

The *Lama* is diſtinguiſhed by having a bunch on the breaſt, and the back ſmooth, *Linn.* This animal deſcribed by ſeveral old naturaliſts under the name of *Ovis Peruviana*, or Peruvian ſheep, is found in moſt parts of South America, but is moſt plentiful in Peru, where it inhabits, in a wild ſtate, the higheſt and coldeſt parts of the mountains, feeding in numerous herds, and flying with great rapidity on the ſight of mankind. The general ſize of the glama is nearly that of a ſtag, meaſuring four feet and a half in height to the top of the ſhoulders, and about ſix feet in length from the noſe to the tail. The neck is of great length: the head ſmall: the back ſlightly elevated; and the whole animal bears ſome reſemblance to a camel, on a ſmall ſcale. Its general colour is a light ferruginous brown, paler or whitiſh on the under parts, and ſometimes it is ſaid to be varied or patched with darker and lighter ſhades on different parts, and to have a black ſtripe down the back to the beginning of the tail. The hair on the wild animal is long and ſhaggy. On the breaſt is a protuberance, from which is obſerved to exude a yellowiſh kind of oily ſecretion. The voice of the glama reſembles the ſhrill neighing of a horſe. When angry or attacked, it ſtrikes with its feet, endeavours to bite, and at the ſame time ejaculates from its mouth a quantity of ſaliva, which is commonly aſſerted to be of a cauſtic or acrimonious nature, and to excite a ſlight inflammation of the ſkin, but Molina thinks this obſervation deſtitute of truth.

Buffon is perſuaded that the lama, or glama of the Peruvians is the ſame animal as thoſe people call guanaco, or huanaco, the former being altered from its primitive appearance by domeſtication. Molina is entirely of a different opinion, and we have recently had an opportunity of aſcertaining that the Peruvians do themſelves conſider theſe two animals diſtinct, and are well acquainted with both kinds in a wild ſtate, as well as that of domeſtication. It is ſingular, as Buffon remarks, that although the lama, and two or three other analogous animals are bred in Peru and Mexico, as the horſes are in Europe, or the camels in Arabia, we ſcarcely know any thing concerning them; and notwithſtanding the Spaniards have had poſſeſſion of thoſe vaſt countries for above two centuries, not one of their authors has given us an accurate hiſtory, nor any exact deſcription of them. It is affirmed that they cannot be tranſported into Europe, nor even brought from their heights but at the riſk of their lives in a ſhort time. But this is not entirely true: it is certain that after the conqueſt of Peru, ſome of them were tranſported into Europe. The animal ſpoken of by Geſner under the name of allocamellus, and of which a figure is given in his work, is of the lama family, (guanaco) and was brought alive from Peru to Holland in 1558. In 1777 there was a living lama in the veterinary ſchool of Alfort, the ſame no doubt from which Buffon took his deſcription of this animal. It was remarkable for the mildneſs of its manners and diſpoſition. When ranging at large it ſeldom walked, but proceeded in a ſort of trot or gallop. This animal ſubſiſted on herbage, and has been known to neglect drinking for the ſpace of ſix months together, ſo abundant was the ſaliva with which the mouth was conſtantly moiſtened.

Peru, according to Gregoire de Bolivar, is the native country of the lamas: they have been conveyed into other provinces, but more for the ſake of curioſity than utility: In Peru, from Potoſi to Coracas, theſe animals are in the greateſt numbers: they conſtitute the chief riches of the Indians, and add not a little to the wealth of the Spaniards. Their fleſh is excellent food, having the flavour of mutton. Their wool may be ſpun into beautiful cloathing; and they are capable of carrying heavy loads in the moſt rugged and dangerous ways. The ſtrongeſt of them will travel with from one hundred and fifty, to two hundred and fifty pounds weight on their backs: their pace is ſlow, and their journey is ſeldom above fifteen miles a day; but though ſlow in their progreſs, they are ſure-footed, eaſily deſcending precipices, and travelling ſafely amongſt the moſt craggy rocks, where men can ſcarcely accompany them. They commonly travel for about five days together, and are then obliged to reſt for two or three days before they reſume their journey. They are conſtantly employed in the mine territory for conveying the Peruvian ores over the rugged hills and narroweſt paſſes of the Andes. Bolivar affirms, that in his time, above three hundred thouſand of theſe animals were kept in conſtant employment by theſe means. A Peruvian drawing lately brought to England, in which an Indian cavalcade is repreſented, exhibits two figures of theſe animals laden with bars of ſilver, according to the coſtume of that country: each lama bears two of theſe bars which are ſuſpended in a ſort of ſaddle, one on each ſide of the animal.

The growth of the lama is very quick, and its life is but of ſhort duration. At the age of three years it couples, and remains ſtrong and vigorous till twelve, after which it begins to decline, and becomes entirely uſeleſs at the age of fifteen. In their nature they appear modelled after that of their Indian maſters; they are gentle and phlegmatic, performing every thing with the greateſt leiſure and caution. When they ſtop on their journey to reſt, they bend their knees very deliberately in order to lower their body without diſturbing their load, and when they riſe again at the command of their driver's whiſtle, it is performed with the ſame precaution: when wearied no blows can provoke them to proceed. They feed as they go along on the graſs they meet with in their way; but they never eat in the night, making uſe of that time to ruminate. When they ſleep or ruminate, they reſt with their feet folded under their bellies. If overloaded or too much fatigued they ſink down, and will not riſe again though the driver ſhould beat them with the utmoſt force; and if the driver continues his torments, the animal grows deſperate, and deſtroys himſelf by beating his head againſt the earth.

This animal may be truly conſidered as the camel of Peru. Even before the diſcovery of South America by the Spaniards, the lamas were domeſticated, and employed as beaſts of burthen by the Peruvians. At preſent they are preferred to horſes by travellers paſſing over the mountainous regions of this part of the world. Cozer, who lately made a journey of obſervation in Peru, tells us the Spaniards harneſs them, and employ them for the conveyance of merchandiſe in the ſame manner as the Peruvians did in former days. A good lama coſt him eighteen ducats; but the ordinary price is from twelve to thirteen ducats each. The fleſh of the young lamas is excellent; that of the old ones is dry and tough. The wool is valuable: the Indians make ſhoes of the ſkin, and the Spaniards uſe it for harneſs. Theſe uſeful and even neceſſary animals in the country they inhabit are attended with no expence to their maſters; as they are cloven footed, they do not require ſhoes, and their wool renders ſaddles unneceſſary. Satisfied with a ſmall portion of vegetables, or graſs, they want neither corn nor hay; and they are ſtill more moderate in what they drink, as their mouths are continually moiſtened with ſaliva, which they have in greater quantity than any other animal.

The lamas Buffon ſuppoſes to be confined to that chain of mountains which ſtretches from New Spain to Terra Magellanica, and he therefore concludes that they are the natural inhabitants of the higheſt regions of the globe, and require a purer and more rarefied air than that of our higheſt mountains in Europe. A recent writer, in an anonymous hiſtory of Peru lately publiſhed, obſerves, that the animals named llamas, pacos, vicunas, and huanacos, are natives of the lofty mountains of that country; and ſtates as a ſingular particular, that although thoſe mountains extend, under the denomination of Cordilleras, to ten degrees of north latitude, with pretty nearly the ſame proportion of elevation and cold, theſe animals do not paſs from the line towards the north, and are conſequently not to be found in the provinces of Quito, Santa Fé, and others, where the climate of the mountains at leaſt is analogous to that of high Peru, in which latter territory the animals in queſtion live naturally, and multiply their ſpecies. The ſole reaſon adduced, to account for this extraordinary circumſtance, is, that throughout the whole extent of the northern mountains of the Cordilleras, a kind of paſture which the Peruvians name *ycho*, or *ychu*, and which is denominated by the authors of the Flora of Peru *xarava*, is not to be found. This plant belongs to the gramineous tribe, and appears to be the natural food of theſe animals. It is extremely abundant in the mountains of Peru; but in thoſe of Quito, Santa Fé, &c. obſervers have not hitherto ſucceeded in aſcertaining its preſence.—This plant has been called by ſome *ichu*, and *pajon*: it is deſcribed flouriſhing luxuriantly on the loftieſt pinnacles of thoſe mountains amidſt the ſnow and ice with which they are perpetually overmantled.

The lamas couple with difficulty from a natural defect in the ſtructure of the ſeveral organs of both male and female. It is oftentimes the labour of ſome hours, or even of a whole day, all which time is ſpent in growling, quarrelling, and ſpitting at each other. The Indians aſſiſt them on ſuch occaſions. They go with young five or ſix months, and ſeldom produce more than one at a birth. The female parent has two teats, and the young one follows her as ſoon almoſt as it is brought forth.

This animal is known by various names among old writers: it is called *ovis peruanana*, Charlet; *ovis peruana*, and *pelon ichiatl oquitli*, Hernand. hiſt. Mexico; *hirſchcamel*, Geſn.; *camelus peruvianus*, *glama dictus*, Ray; *camelus pilis breviſſimis*, Briſſ.; *llama*, Ulloa voy.; and *lama*, Buffon.

Camelus *Huanacus*, the *huanaco*, or *guanaco* of Molina's Natural Hiſtory of Chili, is diſtinguiſhed ſpecifically, according to this author, by having the body hairy, back gibbous, and the tail erect.

This animal, which Buffon conſidered to be the ſame as the former ſpecies in a ſtate of wildneſs, is ſeparated from it by late authors with much propriety, on the authority of Molina. The Peruvians themſelves, as already intimated, make the ſame diſtinction between theſe two animals, ſo that we cannot heſitate to believe them different. It ſhould however be ſtated at the ſame time, that there are European naturaliſts of credit who coincide in ſentiments with Buffon to this day, that the huanaco is the original race from which the lama has proceeded.

Molina offers ſome cogent reaſons in ſupport of his opinion to the contrary. The lama, as he remarks, has the back nearly ſtraight or level; the four limbs of an equal length, and an excreſcence on the breaſt which is almoſt conſtantly humid with a yellowiſh oily ſecretion. The huanaco exhibits neither of theſe peculiarities, the back inſtead of being level is remarkable for its gibboſity; the poſterior legs are longer than the anterior ones, inſomuch, that in aſcending or deſcending precipices in the chace, it can bound and leap with aſtoniſhing velocity; and there is no trace of the pectoral bunch, ſo conſpicuous in the lama; it is beſides very far ſuperior in ſize, and differs in other leſs ſtriking particulars.

The huanacos are ſtronger, ſwifter, and of a more lively diſpoſition than the lamas: they run like a ſtag, and climb over the moſt craggy precipices with the agility of the goat; and their wool or hair is ſhorter. Their ſize is equal to that of the horſe; the length from the muzzle to the origin of the tail being about ſeven feet, and the height from four to five feet. The back is much arched; the head round, and noſe ſomewhat pointed; the ears ſtraight, and the tail ſhort and aſcending, or turned upwards as in the common ſtag.

Although theſe animals are entirely in a ſtate of freedom, they aſſociate in herds ſometimes to the number of two or three hundred. When a man approaches they regard him at firſt with aſtoniſhment, without expreſſing any fear, but ſhortly, as if by common conſent, they blow through their noſtrils, neigh like horſes, and then, by taking a general flight, ſeek a refuge on the tops of the mountains. They prefer the north to the ſouth ſide of the hills. They often remain above the ſnowy tracts of the mountains; and when travelling on the ice covered with hoar froſt, they ſeem to be in the beſt condition, appearing the more vigorous in proportion to the coldneſs of their ſituation. The natives of Chili hunt the huanaco for the ſake of its fleece: the dogs have much trouble to follow them, and if they can once gain the rocks, both the hunters and their dogs are oftentimes compelled to give up the chace. They are very numerous all along the chain of the Cordilleras, which are full three thouſand fathoms above the level of the ſea at Peru, and preſerve that elevation from Chili to the ſtraits of Magellan. At the beginning of winter they quit the higher parts of the mountains which they inhabit during the ſummer, and deſcend into the vallies or plains below in troops commonly of one or two hundred together. The adults run with prodigious velocity, inſomuch that they can be ſcarcely overtaken with the ſwifteſt horſe. The natives are dexterous in purſuing theſe animals, and ſometimes take them alive. The fleſh of the young ones, according to Molina, is as good as veal; that of the full-grown animals is hard and dry, but is better ſalted than freſh. The hair is employed in making caps or hats, and in the fabrication of ſome ſorts of Peruvian cloth.

Camelus *Arcuanus*, the *chilihuque*, or as ſometimes called the Peruvian camel, moutons de Perou, and aries moromorus, is another animal of this family: the body is woolly and ſmooth; ſnout curved upwards, and ears pendulous. It is thus ſpecifically deſcribed by Molina. upon whoſe authority it is inſerted by Gmelin, in his edition of the Linnæan Syſtema Naturæ, as a ſpecies diſtinct from the reſt.

This ſpecies inhabits Peru and Chili, and is deſcribed as meaſuring about ſix feet in length, and nearly four in height. It is covered with woolly hair, and in its general appearance is not unlike a ram. The ears are flaccid or pendulous, the neck and legs long; tail like that of a ſheep, but ſhorter in proportion; the wool is very ſoft, and the colour of the animal is ſaid to vary in different individuals, being either brown, black, aſh-coloured, or white. This animal was employed by the ancient inhabitants of Chili as a beaſt of burthen, as well as in ploughing; its wool was alſo uſed by them in the manufacture of a fine ſilky cloth, or ſtuff. Its fleece is employed for a ſimilar purpoſe at this time.

CAMELUS *Vicugna*, has the body ſmooth and woolly; noſe flat, blunt, and tail erect. Molin. Hiſt. Nat. Chili. *Vicuna*, *Vicuñna*, and *Vicunnas*, *Vicognes*, and *Vigogne* of different authors.

The vicuna bears a general reſemblance to the glama, but is of a lighter and more delicate appearance, and of a ſmaller ſize; the head ſmaller, and ſhorter in proportion; the eyes remarkably large and full; the ears ſomewhat ſharper; and the limbs more ſlender. The colour on the upper parts is a reddiſh brown, and the remainder of an iſabella colour, except the breaſt, belly, inſides of the thighs, and under part of the tail, which are white. The hair of this animal is of a very ſoft, wavy, and woolly nature, that on the breaſt is nearly three inches long; on the other parts not more than one inch; the end of the tail is furniſhed like the breaſt with long woolly hair. The individual deſcribed by Buffon was of a ſomewhat fierce diſpoſition, and frequently attempted to bite thoſe who examined it. It was never obſerved to drink, and ſeemed to have the ſame general habits and manners as the glama.

This animal inhabits the loftieſt ſummits of the Andes, and is allowed to afford a much ſuperior wool to that of either of the former ſpecies. It was once domeſticated in Peru as the lama is at preſent; but the breed is now loſt, and they are only to be found at this period in a ſtate of nature among the mountains. The natives often go in purſuit of the vicunas which they chaſe with dogs, or take by ſtratagem, and kill them chiefly for the ſake of their wool. It is clearly proved from paſt experience, that theſe uſeful animals might be domeſticated with eaſe, and that their domeſtication would be attended with conſiderable advantage to individuals, and benefit to the ſtate, were proper regulations adopted for this purpoſe. But unleſs ſome ſalutary meaſures are taken, there is reaſon to believe the whole race of theſe animals will be exterminated in a few years. When the Indians go out in chace of them, their only object is to deſtroy as many as poſſible. It was no uncommon circumſtance till of late years for a troop of theſe hunters to return home from the purſuit with the ſkins of five hundred, or perhaps a thouſand of theſe animals. The hair is ſold to the merchant upon the ſkin, that he may be aſſured it is the genuine product of the vicuna, and not of the paco, which is rather of a coarſer quality. Very fine cloth is woven with the vicuna wool, both in Peru, and in Spain, to which country it is exported from Peru. Buffon ſuppoſes the vicuna would be a valuable acquiſition to Europe, could the breed be introduced, and propagated with ſucceſs: he is led to imagine that they would thrive well on the Pyrennées and the Alps, nor is this improbable. It ſeems indeed to be in the contemplation of the preſent government of France, to bring the experiment to iſſue by the introduction of theſe animals from Peru into thoſe mountainous regions, as Buffon ſuggeſted; ſo fully are the French agriculturiſts of this time ſatisfied of its practicability, and of the ſucceſs that would attend it.

In the year 1774, a cloth-worker in Paris of the name of Breton, fabricated a piece of cloth of the vicuna wool, in its natural colour, which anſwered extremely well, and was ſubmitted to the inſpector general of commerce as an eſſay deſerving the attention of government, and likely to become an object of public utility. He alſo dyed pieces of this cloth of various colours, as dark and light blue, crimſon, violet or purple, and ſcarlet, and all with an equal degree of ſucceſs. Other experiments were alſo tried by the French manufacturers ſhortly after that time. Shawls in particular, formed of the vicuna wool, under the direction of M. Decretot of the Louviers, are reputed to have been of great beauty; and in the delicacy of texture, and ſoftneſs, to emulate the rich ſhawls of Caſhmire. Theſe particulars will be ſufficient to ſhew of what real utility the cultivation of the vicuna with due attention might become hereafter in Europe.

CAMELUS *Paco*, the *paco*, *alpaco*, and *alpaque* of various authors, an animal nearly reſembling the vicuna, and ſpecifically diſtinguiſhed by having no bunches; body woolly; and ſnout oblong.

This ſpecies is ſaid to be entirely confined to Peru, where the natives keep vaſt flocks of them for the ſake of their wool, of which they prepare cloth of a ſilky luſtre and ſoftneſs: Like the Vicuna, it is found in mountainous diſtricts in large herds, but is never obſerved to aſſociate with thoſe animals. Some ſay it is of a more robuſt make than the vicuna, and is covered with very long wool, which, in the wild animal, is of a dull purple colour, beneath white, and when tamed, varying with black, white, and tawny.

The pacos are conſidered as a ſubordinate kind of animal to the lamas, much in the ſame proportion as we value the aſs with regard to the horſe: they are ſmaller, and not ſo ſerviceable, but their fleeces are more uſeful. Their wool is fine and long, only of a coarſer quality than that of the vicuna, and, with the latter, forms a conſiderable article of merchandiſe in South America.

In a domeſtic ſtate, the pacos are called by the Peruvians alpaques. The natural colour of the wool or fleece of the wild pacos, which reſembles that of a duſky roſe, or rather more inclining to purpliſh brown, is ſo fixed, that it undergoes no alteration under the hands of the manufacturer. They not only make good gloves and ſtockings of this wool, but alſo weave it into quilts and carpets, which ſell at a high price, and form a valuable part of the Spaniſh commerce. The pacos poſſeſs many things in common with the lamas: they belong to the ſame country, and are nearly of the ſame diſpoſition and manners: they bear much reſemblance in figure to the lamas, but are ſmaller: their legs ſhorter, and their muzzles thicker and cloſer.

The wild pacos inhabit and paſture on the higheſt parts of the mountains. Snow and ice ſeem rather to refreſh than to be inconvenient to them: they keep together in flocks, and run ſwiftly. They are timid animals, for as ſoon as they perceive any perſon, they take flight, driving their young before them. The ancient monarchs of Peru rigorouſly prohibited the hunting of them, becauſe they multiply ſo ſlowly; but ſince the arrival of the Spaniards in thoſe parts, their number is greatly decreaſed. The fleſh of theſe animals is not ſo good as that of the huanaco: they are chiefly ſought after for their fleece, and the bezoars they produce. The method of taking them proves their extreme timidity. The hunters drive a flock of them into a narrow paſſage, acroſs which they have ſtretched cords about four feet from the ground, with a number of pieces of linen or woollen cloth hanging to them. The animals are ſo intimidated at theſe rags, agitated by the wind, that they ſtop, and crowding together in a heap, are killed with the greateſt eaſe. But if there happen to be any of the huanacos among the flock, as they are leſs timid than the pacos, they leap over the cords, and the example being followed immediately by the whole drove, they eſcape for that time from their purſuers.

As to the domeſtic pacos, they are employed to carry burthens, like the lamas, but they can only bear a much leſs weight in proportion to their ſize than the lama, ſeldom carrying more than from fifty to ſeventy pounds. They are, beſides, of a more ſtubborn nature, and when once they lie down with their load, they will ſuffer any torment ſooner than riſe. The Indians never make uſe of the milk of theſe animals, becauſe they have ſcarcely enough to ſupply their own young. The great profit derived from their wool induced the Spaniards to endeavour to naturalize them in Europe: they tranſported numbers of them to Spain with this view, but the climate not agreeing with their nature, they all died. Thoſe who brought them into Spain did not conſider, that they cannot exiſt even in Peru, but in the coldeſt regions, and on the ſummits of the loftieſt mountains: that they are never found in the vallies, and if tranſported to warm countries, cannot long ſurvive the change from their natural climate. Had they been ſent to the Pyrennées, or other Alpine regions, it is poſſible they might have aſcended the mountains till they found of themſelves a climate ſuited to their nature. At leaſt, the experiment muſt be ever fruitleſs, unleſs they can be accommodated with a climate as nearly agreeing with their own as the coldeſt parts of Europe will allow.

Such animals as ſubſiſt on vegetables, and live on the high mountains of Aſia and Africa, produce that kind of animal concretion called bezoar, the virtues of which were formerly ſo highly extolled. The pacos produce that particular ſort known by the name of occidental bezoar, in great abundance, as do alſo the huanacos, and the reſt of the lama tribe, or Peruvian camels; but it is only from thoſe animals, when in a ſtate of nature, that bezoar of any value can be obtained. See Bezoar.

The paco is conſidered by ſome naturaliſts as an animal forming an intermediate ſpecies between the lama and vicuna. Molina, in his "Voyage to Chili," has given a good deſcription of the paco, the reſult of which proves, that the paco is more robuſt than the vicuna, has a much longer muzzle, and fleece of longer wool, but not ſo fine. The Peruvians keep vaſt flocks of them for the ſake of their wool, with which they fabricate ſtuffs that have the brilliancy of ſilk. This animal, which appears, however, to be ſo abundant in Peru, we are told, is not found in Chili, either wild or in a ſtate of domeſtication.

Camelus, in *Zoology*, a ſpecies of Trichoda, found in vegetable infuſions. This is thickiſh, hairy before, and emarginate on each ſide in the middle. Müll. Zool. Dan.

Camelus, camelus indicus, camelus indicus verſicolor, and camelopard of different writers are ſynonyms of the Linnæan cervus camelo-pardalis, and Gmelinian Camelopardalis *Giraffa*, which ſee.

CAMEN, or Kamen, in *Geography*, a town of Germany, in the circle of Weſtphalia, and county of Marck; 20 miles S. of Munſter.

CAMENZ, a town of Luſatia; 21 miles N.E. of Dreſden, and 13 W.N.W. of Budiſſen.

CAMERA, in *Antiquity*, derived from the old German *Cam*, *Cammer*, crooked, whence our Engliſh *kembo*, arms in kembo. At firſt it ſignified any winding or crooked plat of ground, as "unam cameram terræ," *i. e.* a nook of land. Afterwards the word was applied to any vaulted or arched building; and it was uſed in the Latin law-proceedings for the judge's chamber, &c. "camera ſtellata," the ſtar-chamber, &c.

Camera, or Cameria, called alſo *Camers*, in *Geography*, a city of great note in Umbria. See Camerina.

Camera, *Ital.* a chamber. This word, when joined to another, becomes a *muſical* term: as *muſica di camera*, compoſitions for a ſmall band; *voce di camera*, a feeble voice.

*Muſica di camera* is one of the three ſpecies of compoſition under which all muſic may be compriſed: as *muſica di chieſa*, church muſic; *muſica teatrale*, theatrical muſic, including muſic for public concerts; and *muſica di camera*, chamber muſic.

Camera *Æolia*, a contrivance for blowing the fire, for the fuſion of ores, without bellows; by means of water falling through a funnel into a cloſe veſſel, which ſends from it ſo much air or vapour as continually blows the fire: if there be the ſpace of another veſſel for it to expatiate in by the way, it there lets fall its humidity, which otherwiſe might hinder the work. The contrivance was named *camera Æolia* by Kircher. Hook, Phil. Coll. N° 3. p. 80. See Bellows.

Camera *lucida*, a contrivance of Dr. Hook for making the image of any thing appear on a wall in a light room, either by day or night. Oppoſite to the place or wall where the appearance is to be, make a hole of at leaſt a foot in diameter, or if there be a high window with a caſement of this dimenſion in it, this will do much better without ſuch hole, or caſement opened. At a convenient diſtance, to prevent its being perceived by the company in the room, place the object or picture intended to be repreſented, but in an inverted ſituation. If the picture be tranſparent, reflect the ſun's rays by means of a looking glaſs, ſo as that they may paſs through it towards the place of repreſentation; and to prevent any rays from paſſing aſide it, let the picture be encompaſſed with ſome board or cloth. If the object be a ſtatue, or a living creature, it muſt be much enlightened by caſting the ſun's rays on it, either by reflection, refraction, or both. Between this object and the place of repreſentation put a broad convex glaſs, ground to ſuch a convexity, as that it may repreſent the object diſtinctly in ſuch place. The nearer this is ſituate to the object, the more will the image be magnified on the wall, and the further the leſs; ſuch diverſity depending on the difference of the ſpheres of the glaſſes. If the object cannot be conveniently inverted, there muſt be two large glaſſes of proper ſpheres, ſituate at ſuitable diſtances, eaſily found by trial, to make the repreſentations erect. This whole apparatus of object, glaſſes, &c. with the perſons employed in the management of them, are to be placed without the window or hole, ſo that they may not be perceived by the ſpectators in the room, and the operation itſelf will be eaſily performed. Phil. Tranſ. N° 38, p. 741, ſeq.

Camera *Obſcura*, or Dark Chamber, in *Optics*, a machine or apparatus ſo conſtructed, that principally by means of a convex glaſs, or a convex glaſs and plane mirror, the images of external objects are repreſented on a rough ground plane glaſs, white paper, white wall, or other ſurface, in the moſt vivid and diſtinct manner, with all their natural motions, colours, ſhades, &c. The firſt invention of the camera obſcura has been aſcribed to Baptiſta Porta.—See his Magia Naturalis, lib. xvii. cap. 6. firſt publiſhed at Frankfort about the year 1589 or 1591. The firſt four books of this work were publiſhed at Antwerp in 1560. But Dr. Freind, in his "Hiſtory of Phyſic," (vol. ii. p. 236) obſerves, that friar Bacon, who flouriſhed in the beginning of the 13th century, deſcribes the camera obſcura, and all ſorts of glaſſes, which magnify or diminiſh any object, bring it nearer to the eye, or remove it farther off. See alſo Bacon's "Opus Majus" by Dr. Jebb, p. 236; and his Epiſtle "ad Pariſienſem," and his "Perſpective" cited by Dr. Plott in his "Hiſtory of Oxfordſhire," p. 215; from which we may conclude, that he had a very accurate and extenſive acquaintance with the properties of various kinds of glaſſes.

Camera *Obſcura*, *the uſe of the*, is manifold: it aſſiſts very much in explaining the nature and rationale of viſion, and hence by ſome it has been compared to the artificial eye. It exhibits the moſt ſtriking and entertaining repreſentations of objects of all deſcriptions, whether near or diſtant, in their true perſpective, the colouring juſt and natural, their light and ſhadows correct, and all their motions and relative poſitions according to the original. By means of this inſtrument, a perſon however unacquainted with drawing, may delineate objects with great facility and correctneſs; and to the ſkilful artiſt it will be found indiſpenſably uſeful in comparing his ſketches with the perfect repreſentations given in the camera, and by obſerving his defective imitations, he may correct, as much as poſſible, his deſigns. To the delineations of that beautiful repreſentation called the *Panorama*, this inſtrument has proved of eſſential uſe.

Camera *Obſcura, the theory of the*, is contained in the following propoſition.

If an external object, as A, *Plate* III. *Optics*, *fig*. 1, radiates its light through a ſmall aperture C, in a ſhutter of a perfectly darkened room upon a white paper or painted ſcreen oppoſite to it, an image of the object will be depicted on the ſcreen in an inverted poſition. For the aperture C being ſuppoſed very ſmall, the rays iſſuing from the point B will fall on *b*: thoſe from the points A and D will fall on *a* and *d*; wherefore, ſince the rays iſſuing from the ſeveral points are not blended, they will, by reflection, exhibit its appearance on the ſcreen. But ſince theſe rays, A C and B C, interſect each other in the aperture, and the rays from the loweſt points fall on the higheſt, the ſituation of the object will neceſſarily be inverted. Hence, ſince the angles at D and *d*, and the vertical ones are equal at C, B and *b*, and A and *a*, will be alſo equal; conſequently, if the ſcreen where the object is delineated be parallel to it, *a b* : A B :: *d* C : DC.

That is, the height of the image will be to the height of the object, as the diſtance of the image from the aperture is to the diſtance of the object from the ſame. This proves, therefore, that the inverſion of the object is not owing to any lens that may be uſed in a camera obſcura. In this manner, the figures of the image are very faint and confuſed, for want of a due degree of light, and its proper refractions.

Camera *Obſcura, conſtruction of a*, whereon the images of external objects are diſtinctly repreſented in their genuine colours, light and ſhade, &c. and either in an erect or inverted poſition.

1. Darken, in the moſt perfect manner poſſible, a room or chamber; in the ſhutter of one of the windows that faces the object to be repreſented, cut a ſmall circular aperture, ſee *fig*. 1. C.

2. In this aperture fix either a double or plain convex lens; if the latter, with the convex ſide next the object. Its focus may be of any length between 3 and 6 feet.

3. At a proper diſtance, to be determined by experiment, or about the focal diſtance of the lens, place perpendicularly a large ſurface of white paper or cloth, and on this the images of the external objects directly before the lens will be beautifully delineated, but in an inverted poſition. The paper or cloth ſhould be moveable, ſo that the exact diſtance of the focus of the lens may be obtained, or the images will not be ſhewn with their utmoſt diſtinctneſs. Thoſe objects alſo ſhould be ſelected that are in the ſtrongeſt light, or illuminated by the ſun's rays. In northern latitudes at noonday, a window oppoſite the north is beſt; in the morning, facing the weſt, and in the evening facing the eaſt. In ſouthern latitudes a window facing the ſouth is beſt at noon. The ſhorter the focus the ſmaller and brighter the images will appear; and the longer, the larger the objects; but if the focus be very long, from 20 to 30 feet, the ſame light being more dilated or ſpread over a large ſurface, the images will appear ſomewhat obſcure, and the colouring fainter. The images will be ſtill brighter if the ſpectator firſt ſtay a quarter of an hour in the dark.

This is the moſt perfect method of obtaining a repreſentation of objects, from having but one refracting medium, but in ſome caſes the inverted poſition of the images may be ſome objection; to obviate which, the following methods may be uſed to make the picture erect. Hold a true ground plain mirror ſlantwiſe againſt your breaſt, under an acute angle, and looking therein, you will ſee all the images reſtored to their natural and erect poſition, and with an addition of luſtre that they will receive from the reflection of the mirror. Or, which is a better way, and does not require a mirror near ſo large, place a mirror above and rather near the lens, ſo as to reflect the rays down upon a white ſurface, a ſcreen directly under, or parallel to the mirror. Or, a large concave mirror may be placed before the picture, at ſuch a diſtance that the image of the picture may appear before the mirror, which will then be erect, and appear pendant in the air. Another method, which is more direct, is by placing another convex lens in a partition behind the paper or ſcreen, with the image at twice the focal diſtance of the ſaid lens, the axes of the two lenſes coinciding, in which caſe another picture of the images will be formed but erect, as large as the firſt, but not ſo bright, and with a contracted field or extent of the picture. Or, two lenſes of ſhort foci in draw-out tubes, may be applied to the hole in the ſhutter inſtead of one, which will alſo produce an erect poſition of the images, but the light will be leſs, the extent very limited, and ſerve only for the repreſentation of buſts, ſmall figures, &c. as hereafter to be deſcribed. This method is but of little uſe and ſeldom practiſed.

The following deſcription of cameras obſcuras has been communicated to us by Mr. William Jones, optician, Holborn, as being the moſt commodious and perfect, and what have been preferred, and are in general uſe, by the moſt ſkilful artiſts:—

*Fig*. 2. repreſents the ſcioptic ball, which is made of mahogany, and conſiſts of three parts, a frame, a ball, and a lens. The frame conſiſts of two pieces in a circular ſcrew rim, fitted one to the other, and both ſo excavated as to admit, and keep ſteady a ſpherical ball perforated, which is voluble in its frame more or leſs eaſily, as the parts of the frame are leſs or more ſcrewed together. At each end the hole in this ball is a ſcrew cell for containing a lens; theſe lenſes are of different focal lengths, and only one is to be uſed at a time, when the images are to be formed. The frame of this ſcioptic ball is to be ſcrewed faſt to the window ſhutter or window board of a well-darkened room, before a hole previouſly made therein. There are two braſs nuts and ſcrews, *a*, *b*, fitted to the frame for that purpoſe; the nuts are ſcrewed to the ſhutter or board, ſo that by means of the ſcrews the ſcioptic ball may be the more readily attatched to, or detached from, the ſhutter. This apparatus is very convenient, when experiments by a variety of lenſes may be deſired. A, *fig*. 2, repreſents the poſition of a mirror when applied for reflecting downwards the images in order to obtain the erect poſitions; if the frame be made to turn on an hinge, it will be the more uſeful to direct the image to an oblique ſcreen, or table, as may be required. *Fig*. 1. repreſents a darkened room with a lens attached to the ſide or ſhutter, or where the ſcioptic ball is to be placed. E repreſents the moveable white paper ſcreen that receives the images of the objects formed by the lenſes, and is moveable to the diſtance of the focal length of the glaſs. A B ſhews the manner in which the buſt, ſtatue, or picture, may be fixed on a ſupport on the outſide of the window, ſo that an image may be formed upon the paper within, from which the artiſt is to copy or delineate. For ſuch proximate objects the focus of the lens muſt be ſhort, from 9 to 12 inches, or the ſcreen will be required to be at too remote a diſtance from the lens. When the diſtance of the object and the image are the ſame from the lens, the image will be of the ſame ſize as the object. When the object approaches nearer, the image will recede and enlarge, and *vice verſâ.*

### *To exhibit Solar Phenomena by means of the Scioptic Ball and Socket.*

The ſcioptic ball affords a very convenient method of forming an image of the ſun in the darkened room. If a lens 10 or 12 feet focus be placed on it, and a white paper ſcreen placed at its focus, in a perpendicular poſition to the rays, a diſtinct image of the ſun will be formed, about one inch diameter, on which will be conſpicuouſly exhibited all the ſpots or ſolar maculæ. At the time of a ſolar eclipſe, the whole progreſs of the moon, from the time of the firſt contact of the limbs to the laſt, may, in this way, be obſerved very diſtinctly. But the beſt method is by connecting a draw-out teleſcope, with the ball of the ſocket, *fig.* 2. by ſcrewing the end with the object glaſs to it, and taking out all the eye glaſſes at the other end, except the one next to the eye, then moving inwards the firſt tube till the image of the ſun appear diſtinct; and you will have a bright image from 12 to 20 inches diameter, according to the diſtance of the ſcreen, which will, to any number of ſpectators, exhibit the ſolar phenomena intended to be viewed.

### *Conſtruction of a Chamber Camera Obſcura.*

The foregoing is the readieſt and moſt ſimple method of converting a room into a camera obſcura, but it is attended with theſe objections, that it only ſerves for objects directly facing the lens, and occaſions always the trouble of darkening the room, fixing and adjuſting the apparatus, &c. *Fig.* 3. repreſents a roof ſhaded like a dome or cupola, placed over a building, proſpect-room, or temporary room erected for the purpoſe of a camera obſcura, and in this way affords the moſt ready and advantageous plan for all ſurrounding objects. The whole dome A B may be made to turn round on friction wheels, in a groove made in the roof for that purpoſe, and to carry round with it the glaſſes in the box C above, or which, in ſome caſes, is a more manageable way, the box with the glaſſes is made moveable in a groove round upon the dome, and is turned by means of a long rod by a perſon within. The manner of fabricating ſuch a dome and box will be evident to any good joiner by a mere inſpection of the figure. The mahogany box C is of a cubical form about 6 or 7 inches in the length of a ſide; a true ground mirror in a frame is placed diagonally in the box, and is moveable ſomewhat on an axis at its lower edge upwards and downwards, to reflect the rays from objects at various diſtances; underneath this mirror, in a round cell, at the bottom of the box, is fixed a double convex lens, about 6 or 8 feet focus, and 4 or 4½ inches in diameter: this lens will form upon a white table D, placed on the floor below, the images of the objects reflected by the mirror above, at the focal diſtance of the lens. The diameter of this table ſhould be 2½ or 3 feet, excavated on its ſurface to a ſmall degree of concavity, or from a radius about the focus of the lens, in order, that the inequality of the diſtance of its ſurface from the centre of the lens, preſenting the images indiſtinct at the circumference, when they are clear in the middle, may be obviated. The ſurface muſt be painted perfectly white, or, which is better, covered with a thin coating of plaſter or ſtucco. The pillar of the table ſhould be made with a ſcrew working in a female one cut in the pedeſtal, ſo that by turning round the table and ſcrew its ſurface may either be elevated or depreſſed, as may be neceſſary, to admit of the cleareſt and beſt defined picture of the images poſſible. To perſons having dwellings upon elevated ſituations commanding extenſive proſpects over countries, rivers, the ſea, &c. a machine of this kind conſtructed over it will afford more delight and entertainment, as well as uſe to an artiſt, than any perſon would imagine, who had not previouſly been a witneſs to ſuch an effect. To thoſe who may not wiſh to be at the expence of a dome, Mr. Jones recommends the box fitted to a wooden pyramidical trunk, (ſee *fig.* 4,) which trunk can be fixed on the ridge of the roof of a houſe or chamber, by a common carpenter, and a flat ſliding cover to ſlide on at A, to cover the trunk when the box of glaſſes B is taken away after uſe. The camera boxes, with the glaſſes complete, and ready for fixing, are made by Meſſrs. Jones, of Holborn, and other Opticians. Metallic mirrors have been uſed inſtead of glaſs ones for cameras; they reflect more light, and conſequently ſhew the images brighter, but their liability to tarniſh and corrode is an inſurmountable objection to their general uſe.

CAMERAS *Obſcuras, conſtruction of portable.* The glaſſes of a camera obſcura are frequently fitted to a portable machine ſhutting up in the form of a cheſt, or book, ſo as to be portable, and eaſily tranſported from place to place, and carried about by the artiſt. The apparatus within is contrived to fold outwards, and form a machine as repreſented at *fig.* 5, and it is contrived upon the moſt convenient plan of any hitherto conſtructed. It is repreſented as placed together for uſe. The lid front A, and the ſlides, one ſhewn at B, by means of hinges turn up to the height of about two feet from the caſe C D E, and are faſtened together by ſmall braſs hooks. The head and ſliding box, with glaſſes F, alſo faſten on by hooks within. The lens of about 25 inches focus is placed under the true parallel glaſs mirror, and forms the images on a white ſheet of paper, placed in the bottom of the cheſt. To view the images the face is applied cloſe to a piece under A for that purpoſe, and to trace the outline, or copy them, the arm at the ſame time is applied in the cloth ſleeve under H. The box F ſlides on a ſquare tube, and by means of a braſs rack and pinion G the lens is adjuſted, while the images are viewing, to its proper focal diſtance from the white paper below. The images formed on the paper have a correct and natural reſemblance to the original objects; no inverſion takes place, and even names and letters on objects are in their direct order. This camera is converted into an inſtrument for magnifying perſpective prints and drawings, and forms the beſt poſſible apparatus for that purpoſe. The head F G and tube are to be entirely removed, as well as the front A, and cloth C D, and another head with a diagonally-placed mirror and large convex lens, *fig.* 6. ſubſtituted, and alſo hooked on. The prints are to be placed at the bottom of the cheſt, and as the camera caſe is open, the print will be illumined either by day light or candle light, as required. The print is viewed by reflection in an horizontal direction, by the eyes being placed before the large convex lens. When the ſides and front are unhooked and folded down into the cheſt, they all lie cloſe, and admit the head to lie under them; and the dimenſions of the cheſt, when thus ſhut up, do not exceed 2 feet in length, 20 inches in breadth, and 5 inches in depth.

The moſt portable kind of Camera obſcura is that repreſented at *fig.* 7, and is that moſt frequently uſed among artiſts, on account of its convenient dimenſions. The images are reflected on a rough ground plane glaſs, and are more vivid than thoſe formed on paper, by the Camera above deſcribed. It is made of mahogany, and of various dimenſions, ſome ſo ſmall as to be carried in the pocket. The lens at the front A is fixed in the cell, in the front of a ſquare draw-out tube, and is of a focus equal to the length of the box when the drawer is half drawn out; and a plain mirror is placed diagonally at the angle of 45°, at the end of the box, as ſhewn by the dotted line *a b*, which reflects the rays tranſmitted by the lens up to the upper ſide of the plane rough-ground glaſs, the rough ſide placed above, under the folding darkening cover, and there forming the images of the objects before the lens at A: the uſe of the draw is to adjuſt the proper diſtance of the lens from the mirror, according to the variable diſtances of proximate objects. The images on the rough glaſs exhibit a beautiful perſpective picture, alſo the profile of a perſon ſeated in a room in a ſtrong light before the camera, and more particularly if the ſun illumine the object; and may be readily traced on the rough ſurface of the glaſs by a black lead pencil, or by what is preferable, red French chalk, and then white paper being gently placed on the glaſs, the lines will be taken correctly off. If very thin white paper is merely placed upon the glaſs, the images may be diſcerned, though faintly, ſufficient to afford the means of tracing correctly. The nearer the object or features are to the camera the larger will be the image, and an additional lens of a ſhorter focus is ſometimes fitted to be ſubſtituted for the other, when the images of very near objects are wanted. Some artiſts who take profiles take out the rough glaſs from its cell, invert the camera, and by a ſtand ſupport it about 10 or 12 inches above the white paper on the table. The image will then invertedly be formed on the paper, and they trace it with a pencil in a correct manner, and with leſs trouble than by the other method. Meſſrs. Jones, of Holborn, make an improved camera of this kind, by joining the ſide of the camera and drawer in the middle with canvas cloth, as ſhewn at the lines B G: the back C turns inward with the mirror, cloſe up to the rough glaſs, and the front E F above, over the top, ſo that the whole camera may fold down into a flat form, and go into a very portable flat leather ſtrap caſe, making it the moſt portable poſſible for perſons travelling. Incluſive of the rough glaſs has ſometimes been placed a double convex lens to relieve the images, and from more light being thus refracted, the images are ſhewn with great beauty and extraordinary brightneſs, even ſurpaſſing the original. They are alſo more vivid when the rough glaſs is placed over this lens, though the contours, or outlines, are not ſo ſharp or diſtinct as when the rough glaſs is uſed only by itſelf. This improvement was aſſumed ſome years ago, by a perſon of the name of Storer, as a diſcovery, and called a *delineator*, but without the leaſt pretenſions, it being previouſly well known by the moſt eminent opticians, and it was, in the year 1758, noticed by Mr. Hooper, in his Rational Recreations, vol. ii. p. 29. Guyot's Recreations Phyſiques, tom. ii. recr. 35. art. 2. Mr. Harris, in his "Optics," b. ii. § 4. has deſcribed a variety of contrivances for converting the portable camera into a ſhew box for viewing prints.

CAMERARIA, in *Botany* (named by Plumier in honour of Joachim Camerarius jun. a phyſician and botaniſt of Nuremberg, who flouriſhed in the latter part of the 16th century, and publiſhed an improved edition of Matthiolus in Latin and German, and ſome other botanical works). Linn. gen. 300. Schreb. 423. Willd. 484. Juſſ. 145. Vent. 2. 423. Claſs and order, *pentandria monogynia*. Nat. ord. *Contortæ*. Linn. *Apocineæ*.

Gen. Ch. *Cal.* perianth one leafed, ſmall, with five acute teeth. *Cor.* funnel-ſhaped; tube long, ſwelling out at the baſe and at the top; border flat, with five lanceolate oblique ſegments. *Stam.* filaments five, ſmall, attached to the middle of the tube; anthers converging. *Piſt.* germs two, with lateral appendages; ſtyle ſcarcely any; ſtigma obſcure. *Peric.* follicules two, horizontally reflexed, oblong, compreſſed, obtuſe at both ends, with two oppoſite lobes at the baſe of each. *Seeds* numerous, egg-ſhaped, compreſſed, with a membranous ring at their baſe by which they are attached to the receptacle lengthwiſe in a ſingle row, an imbricated manner, and inverted direction.

Eſſ. Ch. *Corolla* contorted. *Follicules* two, horizontal. *Seeds* inſerted by a membrane.

Species, 1. C. *latifolia*, baſtard mangeneel, Linn. Sp. Jacq. Amer. 37. tab. 182. Plum. ic. 72. fig. 1. Brown. Jam. 182. Lam. Illuſt. Pl. 173. fig. 2. "Leaves egg-ſhaped, acute at both ends, tranſverſely ſtriated." A tall elegant tree, about 30 feet high, abounding with an acrid milky juice. *Trunk* ſtraight and thick. *Branches* generally dichotomous. *Leaves* oppoſite, petioled, entire, rather ſtiff, ſhining. *Flowers* white, peduncled, terminating the branches. A native of the Weſt Indies and South America. 2. C. *zeylanica*, Willd. Retz. Ob. 4. p. 24. (Apocin-Nerium, Linn. Zeyl. 404. "Leaves oblong, egg-ſhaped, acuminate, tranſverſely ſtriated in terminal and axillary corymbs. Its leaves are longer and flowers ſmaller than thoſe of the preceding ſpecies. A native of Ceylon. 3. C. *lutea*, Willd. Lam. Encyc. (C. Tamaquarina and Guianenſis, Aubl. 1. p. 260.) "Leaves oblong egg-ſhaped, reticularly veined; umbel peduncled, few-flowered." A ſhrub three or four feet high, four or five inches in diameter. *Stem* with a greeniſh ſmooth bark; branches long, ſtraight, ſubdivided. *Leaves* oppoſite, entire, ſmooth, on ſhort petioles. *Flowers* yellow, large, pedunculated, of a pleaſant ſmell, growing in umbels from the forks of the branches. A native of Guiana. Its branches, when cut, yield a milky juice. The Tamaquarina and Guianenſis of Aublet are ſuppoſed by La Marck and Willdenow to be only varieties of the ſame ſpecies. The flowers and leaves of the latter are ſmaller. 4. C. *anguſtifolia*, Linn. Sp. Plum. Ic. 72. fig. 2. Lam. Illuſt. Pl. 173. fig. 3. "Leaves linear." A ſhrub about eight feet high. *Stem* irregularly branching. *Leaves* oppoſite, entire. *Flowers* looſe, at the ends of the branches. It abounds with an acrid milky juice. A native of the Weſt Indies and South America.

CAMERARIA (Dillen.). See MONTIA *fontana*.

CAMERARIUS, or *Chamberlain*, in *Antiquity*, an officer who had the care of the dormitory in ancient religious houſes.

CAMERARIUS, JOACHIM, in *Biography*, an elegant German ſcholar and biblical writer, was born at Bamberg in Franconia in 1500; and was no leſs diſtinguiſhed for his eloquence than for his knowledge of the languages, hiſtory, mathematics, and politics. He was honoured with the friendſhip of Charles V., Maximilian II., and other princes; and by the diligence and zeal with which he delivered his lectures at Nuremberg, Tubingen, and Leipſic, he very much contributed to promote the cauſe of univerſal ſcience, and more eſpecially the ſtudy of elegant literature. He tranſlated from Greek into Latin, parts of Herodotus, Demoſthenes, Xenophon, Euclid, Homer, Theocritus, Sophocles, Lucian, Galen, Chryſoſtom, Theodoret, Ariſtides, Nicephorus, Gregory of Nyſſa, &c. He alſo wrote in Latin the lives of Melancthon and Heſſius: and compoſed "Commentaries on the New Teſtament," in which, ſays Moſheim (Eccl. Hiſt. vol. iv.), "he expounds the ſcriptures merely in a grammatical and critical manner; and laying aſide all debated points of doctrine and religious controverſy, unfolds the ſenſe of each term, and the ſpirit of each phraſe, by the rules of criticiſm, and the genius of the ancient language, in which he was a very uncommon proficient." The laſt edition of this commentary was printed at Cambridge in 1642. It is bound with Beza's Greek Teſtament, printed at Cambridge in the ſame year. Camerarius frequently quotes a MS. which he deſcribes as ancient, and which is noted 88 in the firſt part of Wetſtein's New Teſtament. He likewiſe publiſhed a catalogue of the biſhops of the principal ſees; Greek epiſtles; accounts of his journies in Latin verſe; epigrams of the ancient Greek poets; a commentary on Plautus; and ſeveral other learned works. Turnebus, H. Stephens, Lipſius, Beza, and many others diſtinguiſhed for their literature, concur in bearing ample teſtimony to his talents and learning. He died in 1574; and left ſeveral ſons, who were eminent for their literary attainments. Gen. Dict.

Camerarius, Joachim, a phyſician of learning and eminence, was born at Nuremberg in 1534, where he received the rudiments of his education. As his mind was early turned to the ſtudy of botany and medicine, with the view of improving himſelf, he viſited the principal ſeminaries in Germany, and thence went to Padua, and afterwards to Bologna, where he took the degree of doctor in 1562. Two years after he returned to Nuremberg, and by his ſuperior ſkill and ability, aided perhaps by the high character his father had borne, who was eſteemed one of the reſtorers of literature, he conciliated to himſelf the favour of the principal perſonages in the city. Under their patronage, in 1592, he founded a medical college, of which he was appointed dean or preſident, and in that ſituation continued to direct the affairs of the inſtitution for the remainder of his life. Mindful of his favourite object, botany, he formed an extenſive garden, ſtored with the choiceſt plants, the cultivation of which he ſuperintended with great aſſiduity. He alſo aſſiſted the landgrave of Heſſe with his advice in forming a botanical garden; and with a view of diſſeminating the knowledge of plants, he purchaſed the collections of Geſner and Wolfe, which he methodiſed, and corrected, and with conſiderable additions from his own ſtores, together with the works of Matthiolus, he publiſhed them in 1586, under the title of "De Plantis Epitome utiliſſima Petri Andreæ Matthioli novis Iconibus et Deſcriptionibus plurimis diligenter aucta," 4to. "Hortus Medicus et Philoſophicus, in quo plurimarum Stirpium breves Deſcriptiones, novæ Icones non paucæ, continentur," 4to. 1588. "Opercula de Re Ruſtica, quibus, præter alia, Catalogus Rei Botanicæ et Ruſticæ Scriptorum veterum et recentiorum inſertus eſt," 1577, 4to. Alſo "De recta et neceſſaria Ratione preſervandi a Peſtis Contagione," 1583, with other ſmall tracts on the ſame ſubject, and three centuries of emblems. On his death, which happened October 11, 1598, he was ſucceeded by his ſon Joachim, in his practice and in the honour of being dean of the college. Haller. Bib. Botan. Eloy. Dict. Hiſt.

Camerarius, Elias Rodolph, ſon of Rodolph John C. a phyſician of eminence at Tubingen, was born in 1640. Following the ſteps of his father, he was made doctor, and ſoon after profeſſor of medicine in the univerſity of Tubingen, which office he held to the time of his death, which happened on the 7th of June 1695. He was author of numerous diſſertations on the ſubject of medicine, in which are detailed ſuch rare caſes as had occurred in his practice. Among them, "Hiſtoria Anatomica Renum et Veſicæ," 1683, 4to. In this he gives an account of a diſſection of a perſon who died of an affection of the kidneys. Of one of the kidneys there only remained the external membrane, which was full of purulent matter, into which the kidney had been reſolved.

By his father "Sylloge Memorabilium Medicinæ, et Mirabilium Naturæ Arcanorum, Centuriæ iv.;" among them are two caſes containing accounts of a portion of the tongue being regenerated, after being removed by an operation. Haller. Bib. Med. et Chirurg.

Camerarius, Elias Rodolph, ſon of the former, profeſſor of medicine at the univerſity of Tubingen, and firſt phyſician to the duke of Wirtemberg, was author of numerous diſſertations and treatiſes on different branches of medicine, which appeared in ſucceſſion from the year 1691 to 1733. He was a learned and ingenious, rather, Haller ſays, than an experienced practical phyſician. His diſquiſitions are alſo on ſubjects that are rather calculated to gratify curioſity, than to advance our knowledge in the method of treating and curing diſeaſes: viz. "An liceat Medico pro Salute Matris Abortum procurare?" 1697, 4to.; "Machinæ Humanæ cum Thermometro, Barometro, et Hygrometro Analogia," 1721, 4to.; "De Calculis in Veſicula fellea repertis," 1724, 4to.; "Magici Morbi Hiſtoria attentius penſitata." Some however are practical. "De Podagra." "De Hydrope Uteri," &c. In his larger work, "Diſſertationes Taurinenſes Epiſtolicæ xx. ad illuſtres Germaniæ et Italiæ Medicos," Tubing. 1718, 8vo. he gives an account of ſome rare and unuſual complaints, which had fallen under his notice; among others, of catalepſy, of mania occaſioned by diſappointment in love cured by exciting terror, of loſs of memory occaſioned by a blow on the hinder part of the head, &c. Haller. Bib. Med. et Chirurg.

CAMERIA, in *Ancient Geography*, a town of Italy, in the territory of the Sabines, according to Livy; called *Camerium* by Pliny, and *Camaria* by Steph. Byz. and Dionyſ. Halic. The two laſt ſay, that it was a colony of citizens from the city of Alba.

CAMERINA, in *Geography*, a town of Italy, in the Eccleſiaſtical ſtate, and marquiſate of Ancona, near the Apennine mountains, the ſee of a biſhop immediately ſubject to the pope, and containing 19 convents; 71 miles N.E. from Rome, and 38 S.W. from Ancona. The ancient city of this name was treacherouſly ſurpriſed in the days of its glory by Dionyſius the tyrant, who delivered it up to the Carthaginians; and, deſtitute from that period of walls or fortifications, it was afterwards demoliſhed, and now lies buried under the ſand. Its territory belongs to the prince de Biſcaris, who has found a number of curious and valuable antiquities.

CAMERINUM. See Camarinum.

CAMERLINGO, or Camarlingo, the chamberlain of the pope's court, or the perſon who has the adminiſtration of the apoſtolical chamber.

The word imports as much as keeper of the chamber, or treaſurer; though the camerlingo has divers other juriſdictions which have no relation to the office of treaſurer. The name anciently denoted a *cubicularius*, or gentleman of the bed-chamber; but this is now expreſſed by *cameriere*. The camerlingo is the moſt conſpicuous officer in the court of Rome; becauſe all the revenues of the holy ſee are managed by the chamber of which he is preſident.

This office was anciently performed by the archdeacon of Rome, a dignity which was ſuppreſſed by pope Gregory VII. as of too great power and intereſt; inſomuch that he could often controul the pontiff himſelf, and generally by his intrigues raiſed himſelf to the papacy. In his ſtead was placed a cardinal, under the title of camerlingo, who is aſſiſted in his function by twelve prelates called clerks of the chamber, *clerici de camera*.

The cardinal camerlingo, on the death of a pope, does not enter the conclave with the reſt, to aſſiſt at the election of a new one, but ſtays without, keeps poſſeſſion of the pope's apartment in the Vatican; and whenever he goes abroad is attended by the Swiſs guards, like the pope himſelf. He even coins money in his own name, and with his own arms; and, in fine, is a kind of vice-pope, governing the eccleſiaſtical ſtate during the vacancy of the holy ſee.

The cardinals have alſo their camerlingo, or treaſurer of their college, diſtinct from that of the pope: the former is elected every year, whereas the latter is for life. The perſon choſen to this office has the receipt of all the revenues belonging to the college, which he is to diſtribute at the end of the year in equal portions to the cardinals then at Rome; thoſe who are abſent having no ſhare therein after they have been ſix months from court.

CAMERON, John, in *Biography*, one of the moſt famous divines amongſt the Proteſtants of France, in the 17th century, was born at Glaſgow, in Scotland, about the year 1580, and taught Greek there, till he removed to Bourdeaux in 1600. Here he acquired ſuch celebrity by the fluency with which he ſpoke Greek, that he was appointed to teach the learned languages at Bergerac. He afterwards became profeſſor of philoſophy at Sedan; but returning to Bourdeaux in 1604, he devoted himſelf to the ſtudy of divinity. Upon being appointed tutor to the ſons of the chancellor of Navarre, he accompanied them to Paris, Geneva, and Heidelberg. After having diſcharged the office of a miniſter at Bourdeaux, which he aſſumed in 1608, for 10 years, he accepted the profeſſorſhip of divinity at Saumur. Upon the diſperſion of that academy by the public commotions in 1621, he removed to England, and taught divinity at his own houſe in London. King James, inclined to favour him on account of his ſuppoſed attachment to the hierarchy, made him maſter of the college, and profeſſor of divinity at Glaſgow; but after holding this office, which he found to be unpleaſant to him, for a year, he returned to Saumur, where he read private lectures. From thence, he removed in 1624 to Montauban; where the diſturbances excited by the emiſſaries of the duke de Rohan, led him to remonſtrate againſt the principles which produced them, with more zeal than prudence. This occaſioned his being inſulted by a private perſon in the ſtreets and ſeverely beaten: and this treatment ſo much affected him, that he ſoon after died, in 1625, at the early age of 46 years. Bayle repreſents him as "a man of great parts and judgment, of an excellent memory, very learned, a good philoſopher, good-humoured, liberal not only of his knowledge, but his purſe, a great talker, a long-winded preacher, little verſed in the fathers, inflexible in his opinions, and inclined to turbulence." He was one of thoſe who attempted to reconcile the doctrine of predeſtination, as it had been taught at Geneva, and confirmed at Dort, with the ſentiments of thoſe who repreſent the deity as offering the diſplays of his goodneſs and mercy to all mankind. His opinion was maintained and propagated by Moſes Amyraut, and ſeveral others of the moſt learned among the reformed miniſters, who thought Calvin's doctrine too harſh. They were called Universalists. Cameron likewiſe maintained the poſſibility of ſalvation in the church of Rome. After his death, his theological lectures were printed at Saumur, in 3 vols. 4to. 1626-28, and afterwards with ſome additional pieces, at Geneva, in one vol. fol. His remarks on the New Teſtament, under the title of "Myrothecium Evangelicum," were printed at Geneva in 1632. Gen. Dict. Moſheim, E. H. vol. v.

Cameron, or the *Black Pagoda*, in *Geography*, lies on the coaſt of Golconda, in the bay of Bengal, between Manchepatam and Cape Palmiras.

Cameron, a river on the weſt coaſt of Africa, S.E. from Calabar river, the entrance of which is N. lat. 4°, and E. long. 11° 20′.

Cameron *Cape*. See Camaron.

CAMERONIANS, in *Eccleſiaſtical Hiſtory*, a ſect or party in Scotland, who ſeparated from the Preſbyterians in 1666, and continued to hold their religious aſſemblies in the fields.

The Cameronians took their denomination from Richard Cameron, a famous field-preacher, who refuſing to accept the indulgence to tender conſciences granted by king Charles II. as ſuch an acceptance ſeemed an acknowledgment of the king's ſupremacy, and that he had before a right to ſilence them, made a defection from his brethren, and even headed a rebellion, in which he was killed. His followers were never entirely reduced till the revolution, when they voluntarily ſubmitted to king William. The Cameronians adhered rigidly to the form of government eſtabliſhed in 1648.

Cameronians, or Cameronites, is alſo the denomination of a party of Calviniſts in France, who aſſerted, that the cauſe of men's doing good or evil proceeds from the knowledge which God infuſes into them; and that God does not move the will phyſically, but only morally, in virtue of its dependence on the judgment of the mind. They had this name from John Cameron, of whom an account has been given under the article Cameron.

The Cameronians are a ſort of mitigated Calviniſts, and approach to the opinion of the Arminians. See Universalists, *hypothetical*.

CAMEROTTA, in *Geography*, a town of Naples, in the Principato Citra; nine miles S.W. of Policaſtro.

CAMERTA, in *Ancient Geography*, a town to the right of the route from Otricoli to Rimini. Strabo.

CAMES, in *Geography*, a town of the iſland of Cuba; 40 miles W. of Bayamo.

Cames *Point*, a low point two leagues N. from Manta harbour, on the coaſt of Peru.

Cames, in the *Manufactures*, a name given to the ſmall ſlender rods of caſt-lead, of which the glaziers make their turned lead.

Their lead being caſt into ſlender rods of twelve or fourteen inches long each, is called the *came*; ſometimes alſo they call each of theſe rods a *came*, which being afterwards drawn through their vice, makes their turned lead.

CAMICUS, Camici, and Camicos, *Platonella*, or *Platoni*, in *Ancient Geography*, a town of Sicily, on the banks of a river of the ſame name, N.W. of Agrigentum. The river falls into the ſea near Capo Bianco, ſo called from its colour.

CAMIGARA, a town of India, on this ſide of the Ganges. Ptolemy.

CAMIGUIN, in *Geography*, one of the Philippine iſlands, about 10 leagues in circuit, and known by two high woody mountains. N. lat. 9° 30′.

CAMILIANUM, in *Ancient Geography*, a town of Italy, in Umbria, inhabited by the Camelani.

CAMILLA, in *Entomology*, a ſpecies of Papilio, (Nymph. Phal.) found in Europe. The wings are indented, black, gloſſed with blue, with a white band on both ſides, and ſpot of the ſame; poſterior wings beneath at the baſe ſilvery and immaculate. Fabr. &c. This is papilio lucilla of Eſper, and papilio rivularis of Scopoli. This ſpecies deſcribed by Eſper under the name of camilla, is not the above inſect, but the Fabrician P. lucilla.

CAMILLI and Camillæ, in *Antiquity*, boys and girls of ingenuous birth, who miniſtered in the ſacrifices of the gods; and eſpecially thoſe who attended the *flamen dialis*, or prieſt of Jupiter.

The word ſeems borrowed from the language of the ancient Hetrurians, where it ſignified *miniſter*, and was changed from *caſmillus*.

The Tuſcans alſo gave the appellation Camillus to Mercury, in quality of miniſter of the gods.

CAMILLUS, Marcus Furius, in *Biography*, one of the Patrician family of the Furii at Rome, by whom it was firſt raiſed to eminence. In the year of Rome 353 he ſerved the office of cenſor, and in the 10th year of the ſiege of Veii, A.U. 359. B.C. 395, he was created dictator, deſtined, ſays Livy, by the fates to take the city, and to ſave his country. After previous vows, Camillus prepared for proſecuting the ſiege with vigour; and having defeated the united force of the enemy in the field, he led his army to Veii. The aſſailants from without being aided by a choſen band who had entered the city by a mine which had been conſtructed under the walls, and carried as far as the citadel, Veii, which had been the rival of Rome in power, and its ſuperior in ſplendour, was obliged to ſurrender amidſt the ſhrieks and lamentations of the inhabitants, and after having exhibited a ſcene of blood and ſlaughter, which made even Camillus ſhed tears of ſympathy and compaſſion. Eſtimating the opulence of the city by the ſpoils which it yielded to the victors, and reflecting on the importance of this conqueſt, which had been delayed ten years, Camillus is ſaid to have lifted up his hands to heaven, and to have implored the Gods, that "if his own and the good fortune of the Romans appeared too great in their ſight, and that it was neceſſary to counterbalance it by ſome diſgrace, that they would be pleaſed to cauſe it to fall on him alone, and to ſpare the commonwealth." On the day after the capture of Veii, the priſoners were ſold for ſlaves, and the ſums thus raiſed remitted to the public treaſury. The triumph of the dictator was ſingularly magnificent, and the chariot of the victor was drawn by four white horſes; but the pomp and ſplendour of it offended the Roman people; and Camillus, who from this time was regarded as the head of the Patrician party, became an object of popular jealouſy. Camillus, however, after having fulfilled his vows, abdicated the dictatorſhip. Two years after this event, Camillus was again choſen one of the military tribunes, and entruſted with the conduct of an expedition againſt the Faliſci. Having inveſted Falerii, the capital of theſe people, an incident occurred, which afforded him an opportunity of diſplaying a degree of juſtice and generoſity, that was highly honourable to himſelf and to the Roman character. A ſchoolmaſter of the place, to whoſe care the children of all the moſt illuſtrious perſons were committed, contrived, under a pretence of exerciſing them in thoſe appropriate ſports to which they were accuſtomed, to bring them to the Roman lines; and, upon being led to the Roman general, he delivered them into his hands, informing him, that with theſe children, he in effect ſurrendered to him the town which he was beſieging. "Traitor," ſaid Camillus, with a menacing aſpect, "you do not addreſs yourſelf with your impious preſent either to a general or a people that reſemble you. We have indeed no expreſs and formal alliance with the Faliſci, but that which nature has eſtabliſhed between all men both does, and ſhall ſubſiſt between us. War has its rights, as well as peace; and we have learned to make it with no leſs juſtice than valour. We are in arms, not againſt an age which is ſpared even in cities taken by aſſault, but againſt men, armed like ourſelves; men, who without any previous injury from us, attacked the Roman camp at Veii. Thou, to the utmoſt of thy power, haſt exceeded them by a new and different kind of crime; but for me, I ſhall conquer as at Veii, by Roman arts, by valour, works, and perſeverance." After this reproof, Camillus ordered the traitor to be ſtripped, and to have his hands tied behind him; and providing his young ſcholars with rods, he directed them to drive him back into the city and to ſcourge him all the way. Upon their arrival, the citizens, overcome by this inſtance of generous conduct on the part of Camillus, ſent deputies to treat of a ſurrender. Camillus referred them to the ſenate, who admitted the Faliſci into the number of the allies of the Romans, on condition of their defraying the expences of the war. The noble general returned to Rome with a much more ſubſtantial glory than that of his ſuperb and pompous triumph after the capture of Veii. The army, however, was in no ſmall degree irritated by being diſappointed of its expected plunder.

Four years of turbulence ſucceeded the ſurrender of Falerii, during which Rome underwent the changes of a return to the conſular government, of an interregnum, and of a renewal of the adminiſtration by military tribunes. Whilſt the Gauls in their irruption into Italy had advanced as far as Cluſium in Etruria, the Romans were heedleſs of their danger; and encouraged a proſecution againſt their general Camillus, on a charge of having embezzled ſome of the ſpoils of Veii. Well informed with regard to the iſſue of this proſecution, he reſolved to prevent the indignity of a formal condemnation by a voluntary exile. Having taken leave of his family and friends, he advanced in ſilence towards the gates of the city; and then turning about and ſtretching his hands towards the capitol, he ſupplicated the Gods, "that if he were innocent, they would make his ungrateful country regret his abſence as ſoon as poſſible." He then retired to Ardea; and the Romans impoſed upon him a heavy fine. In the courſe of the Gallic war, a party of the Gauls, which had been ravaging the country, whilſt Brennus their general was beſieging Rome, was led by chance towards the city of Ardea. Camillus, as ſoon as he heard of their approach, rouzed the inhabitants to arm in their own defence. His efforts were not ineffectual; under his conduct they marched out to meet the enemy; and falling on them at night, when they had abandoned themſelves to intemperance and diſorder, a great ſlaughter enſued; the whole body of them was diſperſed, and moſt of thoſe who eſcaped were killed by the inhabitants of the country of Antium, whither they had fled. The fame of this victory ſoon ſpread through the neighbouring cities; and the Roman fugitives at Veii were encouraged to rally, and intreated Camillus to take them under his command. With this requeſt he delayed complying, from a regard to the laws of his country, till the citizens in the capitol had confirmed their choice. But as the city was inveſted by the Gauls, it was difficult to gain acceſs to this fortreſs. An intrepid youth, however, undertook the charge, and upon his arrival in the capitol, the ſenate was aſſembled; and he returned as ſpeedily as poſſible with a revocation of the decree by which Camillus had been condemned, and an unanimous nomination of him to the office of dictator. Camillus, thus reinveſted with authority, invited the diſperſed Romans and their allies to his camp; and ſoon found himſelf at the head of 40,000 men. With this force he ſo haraſſed the Gauls, and by cutting off their ſupplies reduced them to ſuch a ſtate of famine and peſtilence, that they negotiated with the beſieged citizens in the capitol; and in the iſſue, the Romans conſented to purchaſe peace by a ſum of gold. Livy relates, that whilſt the gold was weighing, Camillus ſuddenly arrived at the city gates, and prohibiting the payment, the contract for which had not obtained his concurrence as chief magiſtrate, drove the Gauls from the city into their camp. "Carry back," ſays he to the Romans, "that gold into the capitol; and as for you, Gauls, retire with your weights and ſcales; it is with the ſword only that the Romans ought to redeem their country."

Livy adds, that Camillus purſued them in their retreat, and ſo completely deſtroyed them, that not one Gaul was left to carry home the news of their defeat. Polybius, and ſome other writers, aſſert, that the gold was actually paid, and that the Gauls marched back in ſafety with their booty. Camillus, however, was juſtly regarded as the deliverer of his country; and his ſoldiers, on entering the vacant city in triumph, hailed him as Romulus, the father of his country, and the ſecond founder of Rome. This event happened A.U. 365. B.C. 389. In conſequence of it Camillus purified the ground with the cuſtomary expiations, rebuilt the temples, and erected a new one to Aius Locutius. See AIUS *Loquens*. He was continued in his office of dictator for a whole year, contrary to the uſual cuſtom which limited its duration to ſix months; and by his counſel and influence a decree was paſſed for rebuilding the city, and the work was undertaken with great alacrity and ardour. In the year of Rome 366, a formidable confederacy was concerted againſt Rome by ſeveral neighbouring ſtates, and Camillus, with a view to the ſuppreſſion of it, was a third time appointed dictator. Having raiſed a large army for this purpoſe, he ſpeedily accompliſhed it; and returning to Rome in triumph a third time, he laid down his office. The ſpoils and the ſale of the priſoners yielded a large ſum of money, part of which was applied for defraying the charge of three gold vaſes, inſcribed with the name of Camillus, as a memorial of his exploits, and depoſited at the foot of Juno's ſtatue in the capitol.

In order to quell the commotions occaſioned by the ambition of Manlius, who on a former occaſion had ſaved the capitol from the Gauls, Camillus was a fifth time elected military tribune; and he preſided at the tribunal which condemned this brave, but dangerous citizen to death. His ſixth election to the military tribuneſhip, A.U. 374, was occaſioned by the union of the Volſci with the inhabitants of Præneſte againſt the republic; and though he was now advanced in years, and wiſhed to decline public ſervice, he took the command, and completely defeated them. In the year of Rome 387, Camillus was advanced to the office of dictator a fourth time, for the purpoſe of compromiſing the differences that ſubſiſted between the patricians and plebeians, and of maintaining the prerogative of the former. By his authority he prevented the tribunes from propoſing their new laws to the people; but apprehending the threatened conſequences of their reſentment, and adverting to ſome informality that had occurred in the mode of his appointment, he abdicated his office. The approach of an invading army of the Gauls induced the republic again to direct their views to him as their deliverer; ſo that in his 80th year, he was a fifth time appointed dictator, and he cheerfully conſented to ſacrifice the remains of his life to the welfare of his country. On the banks of the Anio he fell unexpectedly on the Gauls, and defeated them with great ſlaughter. Having received the ſurrender of the town of Velitræ, he returned to enjoy the honour of another well-merited triumph. The turbulent ſtate of the republic would not allow the reſignation of his authority. The popular party determined on reſtoring the conſular government; and the tribunes prepared for ſeizing the perſon of the aged dictator on his tribunal. During the tumult he retired to the capitol; and having implored the gods to appeaſe the conteſt, and to avert its fatal effects, he made a vow to erect a temple to Concord, as ſoon as the troubles terminated. The voice of the people prevailed; and it was agreed, in favour of the ſenate, that one of the conſuls ſhould be choſen out of their own body. In order to preſerve the ſuperiority of the patricians, Camillus propoſed to ſeparate the judicial from the arbitrary power in the conſuls, by the appointment of a prætor, who ſhould be elected from the higher order of citizens, and adminiſter juſtice at home. The power of that party was farther augmented by the inſtitution of two curule or patrician ædiles. Camillus, having thus honourably cloſed his fifth dictatorſhip, and erected the temple of Concord, retired from public life; but in the year of Rome 389, B.C. 365, he fell a ſacrifice to a peſtilence that ſwept away a great number of citizens and magiſtrates.

"His memory was ever cheriſhed as one of the greateſt, moſt fortunate, and moſt patriotic chiefs of the Roman republic." It was a proverbial ſaying, much to his honour, that "wherever Camillus was, there was Rome." Thus expreſſed by Lucan in his Pharſalia, lib. v. v. 27.—

> "Vejoſque habitante Camillo,
> Illic Roma fuit"——

Pliny. Plutarch. Rollin's Rom. Hiſt. vol. ii.

CAMILLUS, in *Entomology*, an elegant ſpecies of PAPILIO, (Eq. Achiv.) deſcribed by Fabricius from a ſpecimen in the Bankſian Cabinet. The wings are white, with fulvous bands edged with black: on the poſterior ones a black caudal ſpot. This is of a ſmall ſize, and inhabits the interior of Africa.

CAMINA, in *Ancient Geography*, an iſland of the Mediterranean Sea, on the coaſt of Aſia Minor, near Miletus, and 38 miles from Platæa. Pliny.

CAMINHA, in *Geography*, a town of Portugal, in the province of Entre Duero e Minho, ſeated at the mouth of the Minho, and defended by a fort and garriſon; it contains about 1300 inhabitants, one pariſh-church, two hoſpitals, and two convents; 11 miles N.N.W. of Viana. N. lat. 41° 44′. W. long. 9° 15′.

CAMINI, or *yerva* CAMINI, in *Botany*, an American herb, the ſame with what is otherwiſe called PARAGUAY, or *yerva conpallo*.

CAMINSTIQUIA, in *Geography*, a river of Upper Canada, which diſcharges itſelf into the lake Superior, 30 miles E. of the Grand Portage.

CAMINITZA, a town of European Turkey, in the Morea, ſituate on a ſmall gulf at the mouth of a river of the ſame name, anciently called Olenus, and the river Mela; 24 miles N.E. of Chiarenza.

CAMINOS, in *Ancient Geography*, a place of Africa, in Cyrenaica, upon the route from the Greater Leptis to Alexandria. Anton. Itin.

CAMION, in the *Military Art*, a ſort of ſmall tumbril, or cart with three wheels, which is commonly drawn by two men, and anſwers for carrying bullets, &c. It is very convenient for magazines in cities and fortreſſes. This name is alſo given to a cart with three wheels, from eight to nine feet long in the body, for moving earth with horſes.

CAMIRIUM, in *Botany*. (Rumph. amb. 2. p. 180. tab. 58. Gært. vol. ii. 710. tab. 125. fig. 2.) See ALEURITES.

CAMIRO, anciently CAMIRUS, in *Ancient Geography*, a town in the iſland of Rhodes, ſeated on the W. coaſt, 18 miles S.W. of it, and almoſt oppoſite to Lindus. This was formerly one of the three cities called *Tripolis*: the other two were denominated *Lindus* and *Jaliſſus*. Of this town there remains no traces beſides the name of Camiro, a Greek village, built upon the ſame ſpot.

CAMIS, or KAMIS, in the *Japaneſe Theology*, denote deified ſouls of ancient heroes, who are ſuppoſed ſtill to intereſt themſelves in the welfare of the people over whom they anciently commanded. The camis anſwer to the heroes in the ancient Greek and Roman theology, and are venerated like the ſaints in the modern Romiſh church. Beſide the heroes or camis beatified by the conſent of antiquity, the *mikaddos*, or pontiffs, have deified many others, and continue ſtill to grant the apotheoſis to new worthies; ſo that they ſwarm with camis: the principal one is *Tenſio Dai Sin*, the common father of Japan, to whom are paid devotions and pilgrimages extraordinary.

CAMISA, Porto, in *Geography*. See Lisa.

CAMISADE, in the *Military Art*, a term denoting a ſudden or unexpected attack in the night, and for which a common badge, mark, or ſignal, is agreed on to enable the troops employed in making it to know one another by, particularly in the dark. A white ſhirt or chemiſe, ſtill called camiſe in ſome of the provinces of France, as moſt diſcernible, was commonly made uſe of, from which circumſtance the word took its riſe.

CAMISANO, in *Geography*, a town of Italy, in the Vicentin, belonging to the ſtate of Venice: 7 miles S.E. of Vicenza.

CAMISARDS, or Camisars, an appellation given by the French to the Calviniſts of the Cevennes, who formed a league, and took up arms in their own defence, in the year 1688. In their boldneſs, crimes, and enthuſiaſm they reſembled the Circumcelliones of Africa. The etymology of the name is diſputed; but it is moſt probably formed from camiſade. See Camisade.

CAMISENE, in *Ancient Geography*, a province of Aſia, in Armenia; which had a famous fortreſs, deſtroyed before the time of Strabo. Antonine mentions a village or town of this name upon the route from Nicopolis to Arabiſus. In the Table of Peutinger it is called Comaſſa, and placed 23 miles from Sebaſtia.

CAMISOLE, in *Conchology*, the name given by Argenville to the Linnæan *Trochus Pharaonis*.

CAMITA, or Comita, *iſland*, in *Geography*, lies 3 leagues N.E. from Cape Roſa, near the N.W. part of the peninſula of St. Domingo iſland.

CAMLET. See Camblet.

CAMLETINE, a ſlight ſtuff, formerly made of hair and coarſe ſilk, and reſembling camblet; but now out of faſhion.

CAMLIN, in *Geography*, a river of Ireland, in the county of Longford, on which the town of Longford is ſeated, and which falls into the Shannon.

CAMMA, and Gobbi, two provinces of Africa, in the kingdom of Loango, lying between the province of Sette and the cape of Lobo Gonzales; whoſe inhabitants are at perpetual war with each other, and whoſe country is interſected with lakes and rivers, that afford plenty of fiſh, but are infeſted with ſea-horſes, which are very miſchievous both on land and water, particularly to the canoes and other veſſels, which are continually plying to and fro upon the rivers and marſhes. The language, manners, and cuſtoms of both theſe provinces are almoſt the ſame with thoſe of Loango. They both allow of polygamy, and they are very free in the diſpoſal of their wives for the accommodation of their friends or ſtrangers. Their military weapons are the ſhort pike, bow and arrows, ſword and dagger; and the Europeans have furniſhed them with fire-arms, gun-powder and ball, beſide braſs pots and kettles for domeſtic uſe, and ſeveral ſorts of coarſe cloths. The chief town of Gobbi lies about a day's journey from the ſea. The land breeds little elſe but beaſts of prey. The principal commerce with the natives, beſide the logwood, conſiſts chiefly in elephants' teeth and tails, the hair of which is highly valued, and uſed for ſeveral curious purpoſes.

Camma, a river of Africa, which ſeparates the kingdom of Benin from Loango, and runs into the Atlantic. S. lat. 1° 40′. E. long. 11° 40′.

CAMMANIA, in *Ancient Geography*, a country of Greece, which formed a part of Theſprotia. It is the Ceſtrine of Pauſanias, and was called Ceſtrinia, according to Steph. Byz.

CAMMAS Water, in *Geography*, lies at the mouth of the river running from Morpeth, in Northumberland, and has a ſmall port for ſhipping, corn, and grinding ſtones.

CAMMIN, a town of Germany, in Pruſſian Pomerania, ſeated near the mouth of the Oder, on the lake of Boden, about 3 miles from the Baltic, near the ſee of a biſhop, ſuppreſſed by the peace of Weſtphalia, and united to the dominions of Pruſſia; 35 miles N.E. of Stettin. N. lat. 53° 56′. E. long. 14° 48′.

Cammin *ſound*, is one of the ſmall channels that lead from the Baltic into the channel of the river Oder, up to Stettin.

CAMMOCK, in *Botany*. See Ononis *ſpinoſa*.

CAMMONI, in *Ancient Geography*, a village placed on the Erythræan ſea, in the gulf of Barygaza, according to the periplus of Arrian; and probably the ſame with the *Camane* of Ptolemy.

CAMMOROS, in *Botany*, a name given by ſome of the old writers to a poiſonous plant called by the Romans *cicuta*, or hemlock; ſo that it became hence a name for the mandrake, and ſome of the nightſhades, with ſome authors. Many of the moderns, and even ſome among the ancients, have erred greatly in confounding the *cammoros* with the *cammaros*, which is an inſect, in figure reſembling the root of this aconite. See Comocladia.

CAMOCLADIA. See Comocladia.

CAMŒNA, in *Entomology*, an African Papilio, of the *Heleconii* tribe, deſcribed by Fabricius, the wings of which are ſomewhat entire, fuſcous, and dotted with black, with a red band on the poſterior pair.

CAMŒNÆ, in *Ancient Mythology*, a name given to the Muſes, becauſe it was their principal occupation to celebrate in ſong the actions of the gods and heroes. The camœnæ of Latium, mentioned by Plutarch in Numa, who were ſuppoſed to have ſhewn the ſacred fountain to the Veſtals, were probably, ſays Bryant (Anal. Anc. Mythol. v. i. p. 64.), the original prieſteſſes, whoſe buſineſs it was to fetch water for luſtrations from that ſtream. For Cam-Ain (he ſays) is the fountain of the Sun, and the camœnæ were named from their attendance upon that deity. The hymns in the temples of this god were ſung by theſe women; and hence the camœnæ were made preſidents of muſic.

CAMŒNARUM Lucus, in *Ancient Geography*, the name of a wood in the vicinity of Rome, at the Capena gate, in the midſt of which was the fountain of Egeria, conſecrated by Numa. Livy, l. i. c. 21.

CAMOENS, Lewis de, in *Biography*, a Portugueſe poet, was deſcended of an ancient family of Galicia, in Spain, under the name Caamans, but changed to Camoens, in 1370, when a branch of the family left Spain and attached itſelf to the king of Portugal. Camoens, the poet, ſprung from a younger branch of this family, which had been unfortunate; his father having ſuffered ſhipwreck at Goa, with the loſs of his whole property; and was born, as ſome ſay, in 1517, or according to others, in 1526 or 1527; nor is the place of his birth leſs conteſted than the time of it. Some ſay, that he was born at Coimbra, and others, at Santaren; but Emanuel de Correa, his intimate friend and companion, ſays, that he was born at Liſbon, and that his mother, Anne de Maudo, was of a noble family. He ſtudied in the Univerſity of Coimbra, where he was diſtinguiſhed by his application to the claſſics and to the philoſophy of the times; but his genius principally inclined him to poetry, and, therefore, upon his return to Liſbon, he became known at court by his poetical talents and his gallantry. Being no leſs agreeable in his perſon than in his converſation and writings, he was betrayed into imprudences of a licentious kind, which cauſed him to be exiled, as it has been generally thought, to Santaren in Eſtremadura, the place of his mother's nativity, and the reſidence of ſome of his relations. On this occaſion he compared himſelf, in one of his elegies, to the baniſhed Ovid. Diſguſted with an inactive life, and being naturally brave, he obtained permiſſion to ſerve in a fleet that was ſent to the ſuccour of Ceuta, in Africa, and in a naval engagement he had the misfortune to loſe one of his eyes. His ſtay at Liſbon, whither he returned after this naval expedition, was of ſhort continuance; ſome new cauſe of diſſatiſfaction aroſe, and he was again obliged to leave it; and, therefore, with complaints of the ingratitude of his country, he reſolved to embark for the Eaſt Indies in a fleet commanded by Cabral, which ſailed in 1553. At Goa he volunteered his ſervices in an expedition to the coaſt of Malabar; and after his return, in 1555, he embarked on a ſecond expedition to the Straits of Mecca, in the Red Sea, where, military exertion not being neceſſary, he employed his time in writing, and in viſiting ſome of the adjacent parts of Africa, which he has beautifully deſcribed. Having ſpent the winter at Ormuz, he returned to Goa; but indulging his diſpoſition in compoſing ſome ſatirical pieces againſt Bareto, the Portugueſe viceroy of India, and ſeveral other principal perſons of Goa, he was baniſhed by order of the viceroy to Macao in China. Here he obtained the profitable office of commiſſary of the eſtates of the deceaſed, and in the exerciſe of it acquired ſome property. During a reſidence of five years at Macao, he finiſhed his "Luſiad," which he had begun ſome years before in Portugal. Upon the removal of Bareto, he determined to return to Goa, and having freighted a ſhip for this purpoſe, he was unfortunately ſhipwrecked at the mouth of the river Meco, on the coaſt of Camboja, and loſt his whole property; however, he ſaved his life, and his poems, which he bore through the waves in one hand, whilſt he ſwam aſhore with the other. The natives treated him with hoſpitality; and on this remote coaſt he wrote his beautiful paraphraſe on the 137th Pſalm, which repreſents the Jews as hanging their harps on the willows by the rivers of Babylon. Upon his arrival at Goa, he was kindly received by Don Conſtantine de Braganza, the new governor; but his ſucceſſor, count Redondo, conceiving prejudices againſt him, on account of ſome malverſation in his office at Macao, with which he was charged by his enemies, threw him into priſon. Having cleared himſelf of the charge alleged againſt him, he was detained for debt; and it was in conſequence of an humorous petition, which he preſented to the viceroy, that he obtained his liberty. His next adventure was that of accompanying the governor of Soſala to that ſettlement; but he was deceived by promiſes which were never fulfilled, and treated with ſingular ſeverity. When the governor found that Camoens was determined to leave him, he endeavoured to detain him by making a charge of debt for his board, and threatening to confine him in priſon. Theſe unreaſonable claims were ſatisfied by ſome Portugueſe gentlemen, who invited him to accompany them to Europe; and accordingly he arrived with them in Liſbon in 1569, after an abſence of 16 years. One principal object, which made him deſirous of reviſiting his native country, was the publication of his "Luſiad," which appeared in 1572. This poem, which came to a ſecond edition in the ſame year, was dedicated to king Sebaſtian, who, it is ſaid, allowed him a ſmall penſion of 4000 reals, on condition of his living at court. With this pittance, if it had been continued, Camoens would have lived in peace and comfort; but Sebaſtian ſoon loſt his life in Africa, and upon the acceſſion of Henry, the poet was forgotten, and his penſion was withheld. Thus reduced to a ſtate of deplorable indigence and diſtreſs, a poet, who had produced what at its firſt appearance was thought to do honour to the nation, ſpent the reſidue of his life, humbled and mortified amongſt a few Dominican monks, either in an alms-houſe, or under the charitable roof of a nunnery. It is ſaid, that his black ſervant, a native of Java, who had been his companion for many years, and who aſſiſted in ſaving his life when he was ſhipwrecked, begged in the ſtreets of Liſbon for the ſupport of his maſter, who died in 1579. It is ſaid, that his death was accelerated by the anguiſh with which he foreſaw the ruin impending over his country. In one of his letters he uſes theſe remarkable expreſſions: "I am ending the courſe of my life; the world will witneſs how I have loved my country. I have returned not only to die in her boſom, but to die with her." He was buried as obſcurely as he had cloſed his life, in St. Anne's church; and the following epitaph was inſcribed over his grave:—

"Here lies Lewis de Camoens,
Prince of the poets of his time.
He lived poor and miſerable, and died ſuch,
Anno Domini, 1579."

Some years afterwards a reſpectable monument was erected over his remains, at the expence of a Portugueſe nobleman. "His memory was honoured by numerous eulogies from the poets of Spain and Portugal, and the name of Camoens is ſtill pronounced with enthuſiaſtic veneration by all the votaries of Portugueſe literature." Of the various poetical compoſitions, written by Camoens, the epic poem, entitled "Luſiad," is the only one which makes him known in modern times. The ſubject of this poem is the diſcovery of the Eaſt Indies by the Portugueſe, under Vaſco de Gama; and the fleet is conducted by the poet round the coaſt of Africa to Calicut, on the Malabar coaſt. In the courſe of the voyage the author introduces a great variety of deſcriptions, which his knowledge of the parts of the world to which they relate renders noble and intereſting. Some of his poetical fictions are conceived with true genius; and the giant Adamaſtor, the guardian of the Cape of Tempeſts (ſince called the Cape of Good Hope,) is a creature of fancy as ſublime as the imagination of a poet has produced. "On the whole," ſays Dr. Aikin (Gen. Biog.), the want of a well-connected plan, the neglect of proper decorum, the monſtrous mixture of the Heathen with the Chriſtian mythology, and the general baldneſs and want of elevation in the ſtyle, place this work far beneath the principal epics of ancient and modern times." "The whole work," ſays Dr. Blair (Lectures on Rhetoric, &c. vol. iii. p. 273.), "is conducted according to the epic plan. Both the ſubject and the incidents are magnificent; and, joined with ſome wildneſs and irregularity, there appear in the execution much poetic ſpirit, ſtrong fancy, and bold deſcription." "There is no attempt towards painting characters in the poem; Vaſco is the hero, and the only perſonage indeed that makes any figure. The machinery of the Luſiad is perfectly extravagant; not only is it formed of a ſingular mixture of Chriſtian ideas, and Pagan mythology; but it is ſo conducted, that the Pagan gods appear to be the true Deities, and Chriſt and the Bleſſed Virgin to be ſubordinate agents. One great ſcope of the Portugueſe expedition, our author informs us, is to propagate the Chriſtian faith, and to extirpate Mahometaniſm. In this religious undertaking, the great protector of the Portugueſe is Venus, and their great adverſary is Bacchus, whoſe diſpleaſure is excited, by Vaſco's attempting to rival his fame in the Indies. Councils of the gods are held, in which Jupiter is introduced, as foretelling the downfal of Mahometaniſm, and the propagation of the Goſpel. Vaſco, in great diſtreſs from a ſtorm, prays moſt ſeriouſly to God; implores the aid of Chriſt and the Virgin, and begs for ſuch aſſiſtance as was given to the Iſraelites, when they were paſſing through the Red Sea, and to the Apoſtle Paul, when he was in hazard of ſhipwreck. In return to this prayer, Venus appears, who diſcerning the ſtorm to be the work of Bacchus, complains to Jupiter, and procures the winds to be calmed. Such ſtrange and prepoſterous machinery ſhows, how much authors have been miſled by the abſurd opinion, that there could be no epic poetry without the gods of Homer. Towards the end of the work, indeed, the author gives us an awkward ſalvo for his whole mythology; making the goddeſs Thetis inform Vaſco, that ſhe, and the reſt of the Heathen deities, are no more than names to deſcribe the operations of Providence."

"There is, however, ſome fine machinery, of a different kind, in the Luſiad. The genius of the river Ganges, appearing to Emanuel king of Portugal, in a dream, inviting that prince to diſcover his ſecret ſprings, and acquainting him, that he was the deſtined monarch for whom the treaſures of the Eaſt were reſerved, is a happy idea. But the nobleſt conception of this ſort, is in the fifth canto, where Vaſco is recounting to the king of Melinda, all the wonders which he met with in his navigation. He tells him, that when the fleet arrived at the Cape of Good Hope, which never before had been doubled by any navigator, there appeared to them on a ſudden, a huge and monſtrous phantom riſing out of the ſea, in the midſt of tempeſts and thunders, with a head that reached the clouds, and a countenance that filled them with terror. This was the genius, or guardian, of that hitherto unknown ocean. It ſpoke to them with a voice like thunder; menaced them for invading thoſe ſeas which he had ſo long poſſeſſed undiſturbed; and for daring to explore thoſe ſecrets of the deep, which never had been revealed to the eye of mortals; required them to proceed no farther; if they ſhould proceed, foretold all the ſucceſſive calamities that were to befal them; and then, with a mighty noiſe diſappeared. This is one of the moſt ſolemn and ſtriking pieces of machinery that ever was employed; and is ſufficient to ſhow that Camoens is a poet, though of an irregular, yet of a bold and a lofty imagination."

This poem has been tranſlated into many languages, and illuſtrated by elaborate commentaries. Two Engliſh verſions of it have appeared; one by ſir Richard Fanſhaw, in the 17th century; and another in the latter part of the 18th by William Julius Mickle, A. D. 1776, 4to. "This laſt," ſays Aikin, "is one of the beſt verſified poems in the Engliſh language; but the liberties taken with the original, in large additions, alterations, and omiſſions, beſides a perpetual ſuperiority of poetic language, render it a very flattering repreſentation of the poem of Camoens." Gen. Dict. Introd. to Mickle's Luſiad.

Camoens's *Cave*, in *Geography*, a cave below the loftieſt eminence in the town of Macao in China, ſo called from a tradition current in the ſettlement, that the Portugueſe poet of that name wrote his celebrated poem of Luſiad on that ſpot. This intereſting cave is in the middle of a garden, which commands a very extenſive proſpect.

CAMOGLI, a town of Italy, in the ſtate of Genoa, near the ſea-coaſt; 13 miles E. of Genoa.

CAMOIL, a town of France, in the department of Morbihan, and diſtrict of Vannes, 1½ league W.S.W. of Roche-Bernard.

CAMOMILE, in *Botany*. See Anthemis.

CAMOO, in *Geography*, a town of Japan, in the province of Oomi.

CAMORA. See Zamora.

CAMORTA, a ſmall iſland in the bay of Bengal. N. lat. 8° 8′. E. long. 94° 3′.

CAMOTES, a group of iſlands belonging to the Philippines in the Eaſt Indian ocean, ſituate between Zebu or Cebu, and the coaſt of Ogmuah and Leyte; the chief of which is Poro, dependent on Zebu.

CAMOUCLE, in *Ornithology*, the horned ſcreamer, according to Bajon. See Palamedea *cornuta*.

CAMOUFLET, a ſmoky paper held under the noſe of one that ſleeps. But when this word is made uſe of as a term of war, it ſignifies an affront, a mortification, a diſappointment. An enemy's miner is ſaid to give a camouflet to ours, when he finds means to deſcend or get down into his adverſary's gallery, to make ſome ſmall mines blow up, and thereby to ſtifle or ſuffocate him.

CAMP, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and archbiſhopric of Treves, on the eaſt ſide of the Rhine, oppoſite to Boppart.

Camp, in the *Military Art*, the ground where a corps, body of troops, or army, pitch their tents, and live or dwell in the ſame, either for a ſhorter or longer ſpace of time. In a more general acceptation of the word, it may be defined to be the ſpot or ground where any number of perſons, however ſmall, ſtop or remain in tents, wigwams, huts, or otherwiſe, for one night or a longer time, whether they be in a ſtate of warfare, or engaged in their ordinary purſuits of life. Thus, for inſtance, the ſavages or wandering natives of America are ſaid to encamp; and the ſpots where they have their wigwams, or remain even for one night or two, are called their camps or encampments. Many of them are in as ſimple and uncultivated a ſtate of life as it is poſſible for human creatures to be in. For men neither ever did nor ever can exiſt but in a ſtate of ſociety of ſome kind or other. Ever ſince there have been men, however, there have been diſputes or quarrels. Theſe led to violence and warfare, and obliged thoſe who lived even in the ſimpleſt and rudeſt ſtate of ſociety, to think of and contrive means for ſecuring their encampments againſt ſurpriſe or inſult. For this purpoſe they would naturally make uſe of ſtakes, buſhes, an abatis, a ditch, and occupy ſituations difficult of acceſs, and advantageous in other reſpects. The firſt contrivances and efforts of genius, however, in the way of defence muſt have been rude, defective, and of little moment, ſuited to the ſimplicity of thoſe by whom they were made, who poſſeſſed neither the experience that could lead to the conception of great deſigns, nor the means neceſſary for executing them. Ditches, bordered with bruſh, buſhes, an abatis, or a ſingle row of ſtakes, ſurrounded their huts, tents, or cabins, and formed their whole ſecurity. The Indians in America furniſh, at this moment, many examples of this manner of fortifying. As men advanced in ſocial improvements, and began to have fixed or permanent habitations, they would naturally think of conſtructing walls with wood, earth, and afterwards with ſtones. Julius Cæſar in his time found wooden walls in uſe among the Gauls; and there are ſome parts now in Ruſſia, where the towns are defended or ſecured by walls of wood or timber.

The words made uſe of by the Grecian writers to expreſs a camp, or the camp, are always in the ſingular number, as τὸ ϛρατόπεδον, ἡ παρεμβολή. But the Roman military writers conſtantly uſe the word *caſtra*, in the plural number, to ſignify a camp, or the camp. Some have attempted to derive the word *caſtra* from *caſtro*, making it of the ſame import as *caſtu*, quod ibi caſtraretur libido, and becauſe the Roman ſoldiers were not originally permitted to marry. But the word caſtra is the plural of caſtrum, which Cicero has made uſe of: and caſtrum or caſtra is eaſily and evidently derivable from caſas aſtruere, to erect or build huts or tents adjoining to one another or cloſe together. But no good or even plauſible explanation has been given of the cauſe or reaſon why the Roman hiſtorians invariably employ the word *caſtra* in the plural number, and not *caſtrum* in the ſingular, not only when they mention both the conſular camps when ſeparate, but alſo when they ſpeak only of one of them or of both joined together as one. The following circumſtance, however, probably gave riſe to that practice, or cuſtomary mode of expreſſion, for a camp or the camp. The tribes originally when they went out encamped ſeparately and apart from one another, each by itſelf. The different poſitions or ſpots of ground they occupied, were naturally called the camps, or caſtra; which term or expreſſion growing into uſe was retained when they were encamped together and ſurrounded by one and the ſame ditch and rampart.

It is not probable that either the Romans or any other people originally encloſed their camps on every occaſion with regular ditches and ramparts, but rather that they frequently choſe ſtrong and advantageous ſituations, and depended on watchfulneſs and valour for their ſecurity. It was a very ancient cuſtom, however, among the Greeks, to ſurround their places of encampment occaſionally with a ditch or trench, which they called ὄρυγμα. Homer ſpeaks of the camp which they formed before Troy, and makes them poſt the beſt and braveſt of their troops on the two flanks or wings. The Lacedæmonians, who were trained up in martial exerciſes from the time they were ſeven years of age, and ſtudied war as an art or ſcience more than any other of the ſtates of Greece, were not only well acquainted with the genuine maxims and principles of warfare, but alſo ſkilful, dexterous, and expert in all the methods of carrying them into practice long before the Macedonians, the Carthaginians, and the Romans. They alſo received from their celebrated lawgiver, Lycurgus, the firſt mixed form of government compoſed of the three ſimple ones, viz. monarchy, ariſtocracy, and democracy, that exiſted in Europe. It laſted for many ages; and whilſt they adhered to his laws and inſtitutions, they were alike free from internal diſſenſions among themſelves, and proof againſt ſubjugation by external force. The Macedonians borrowed from them the beſt part of their military regulations and diſcipline. The Carthaginians imitated them, and on one occaſion a certain Lacedæmonian, named Xantippus, who joined them with a body of mercenaries from Greece, by his ſuperior ſkill in the art of war, and dexterous management, defeated the Roman conſul Regulus, who till then had been uniformly victorious over them, and ſaved their ſtate when it was brought to the very brink of deſtruction. The Romans, at an early period, not only adopted ſeveral of their military maxims, precepts, and inſtitutions, but alſo committed them to writing, carefully keeping records of them, and retained them ever after. It has been ſaid, on the authority of ſome writers, that their camp was of a circular form, which was preſcribed by Lycurgus, as fitter for defence than any other. This reaſon, however, aſcribed to that great lawgiver, is not a good or juſt one. For a direct defence from a ſtraight line is much better than from the convexity either of a circle or ellipſe. Beſides this, the obſervation militates againſt facts, and the practice of the Lacedæmonians themſelves in the different wars in which they were engaged. For, like the reſt of the Greeks, they did not obſerve any invariable form or method in their encampments, but chiefly conſulted the nature and ſtrength of the ground they encamped on, and gave to their camp the form and arrangement that beſt ſuited the ſame, employing, on different occaſions, every ſort of figure which the poſitions they occupied required. This erroneous idea, in regard to the figure of the Spartan camp, was probably derived from the circumſtance, that the city of Sparta itſelf was of a circular form. It is not very probable, however, that the Spartans often intrenched their camps, as they did not even ſecure their city with a wall, or rampart, depending on their own vigilance and valour, more than on walls, for its protection. That they ſometimes did, however, cannot be denied. For Cleomenes, when oppoſed to Antigonus, not only occupied ſtrong poſitions, but alſo made uſe of intrenchments, and even abatis. Many other inſtances might likewiſe be mentioned. We know, indeed, from the beſt authority, that the Greeks in general accommodated the figures and diſtributions of their camps to the ſituations they encamped on, ſometimes ſecuring them with trenches and ramparts, but often not. They occaſionally ſuffered ſeverely by neglecting this precaution, of which the Meſſenians furniſh a ſtriking example, when they marched with their forces to join Philip of Macedon, though they encamped cloſe under the walls of a friendly fortreſs. Polybius, in the ſixth book of his general hiſtory, in ſpeaking of the great regularity of a Roman camp, the rules the Romans regularly obſerved in forming it, their invariable cuſtom of ſurrounding it with a ditch and rampart, and the great eaſe and facility with which theſe were made, by each ſoldier's knowing always on what part he was to perform his labour, as well as his own place in the camp, and that of the body he belonged to, contraſts their practice with that of the Greeks; and tells us, that theſe, when they encamped, chiefly conſidered the natural ſtrength of the place they fixed on, and accommodated to it the arrangement and diſpoſition of their encampment, wiſhing partly to avoid the labour of making intrenchments, and partly perſuaded that works raiſed by art are ſeldom ſo ſtrong or ſecure as thoſe that are formed by nature. He ſays, that in compliance, therefore, with what the ſituations demanded, they were not only obliged to give every ſort of figure to their camps, but alſo to vary the poſition of the ſeveral parts of them, as the place for each was favourable or improper; and that from thence it happened that the ſoldier never knew to a certainty his own place in the camp, or that of the body to which he belonged. But the Romans, he informs us, willingly ſubmitted to the taſk of making intrenchments, and to other toilſome labour, for the ſake of the great advantage that was found to ariſe from their employing a method that was never changed, and which rendered all the parts of the camp quite familiar to the army. The Macedonians, who learnt the art of war from the Greeks, and particularly from the Spartans, like them gave their camp every ſort of figure to make it ſuit the ground they encamped on, ſometimes intrenching it, and ſometimes not, as circumſtances ſeemed to require.

Even before Alexander the Great invaded Perſia, the Grecian coloniſts in Aſia and the nations in it who were in the practice of employing Greeks in their armies, encamped nearly in the ſame way, varying the forms of their encampments with thoſe of the poſitions they occupied with them, ſecuring them with intrenchments on ſome occaſions, and on others not. But after the death of that prince, who ſeemed to have been born for the conqueſt of men, both the Egyptians and all thoſe nations of Aſia that had been viſited by his arms, followed very nearly the Macedonian or Grecian method of encamping, and generally when at no great diſtance from their enemies, or in danger of being attacked, ſtrengthened and ſecured their camps with ditches and ramparts. Thus the camp of Molon, who was governor of Media, and had revolted againſt Antiochus, the ſon of Seleucus, was intrenched on the bank of the Tigris. Theodotus the Ætolian, governor of Cœlo-Syria, ſecured the troops he had poſted in the narrow part of the vale of Marſyas, between the fortreſſes of Brenchi and Gerrha, ſo well with intrenchments and paliſades, that the ſaid Antiochus in trying to penetrate that way, ſuſtained ſo great a loſs, that he was obliged to deſiſt from the attempt. Both this king and Ptolemy Philopater, in their conteſt for the ſovereignty of that province, intrenched their camps. And many other inſtances of this practice, ſubſequent to the time of Alexander, might be given.

The Carthaginians, who had an intercourſe with the Greeks, long before their obſtinate contention with the Romans in Sicily for the poſſeſſion of that iſland, followed a ſimilar mode of encamping, changing, like them, the forms of their camps, to make them ſuit the ſituations they occupied, ſurrounding them ſometimes with ditches and ramparts, and ſometimes not, as circumſtances made ſuch precautions neceſſary or otherwiſe. It is probable they paid more attention than formerly both to the ſecurity of their camps, and to regularity in forming them after they came to be engaged in long and obſtinate conteſts with the Romans. It does not appear, however, that the Carthaginian generals, when they ſat down, contrary both to common ſenſe and the rules of military ſcience, with their elephants and cavalry, as well as their infantry, on a rough and craggy eminence near Adis, which Regulus was beſieging, took meaſures for ſtrengthening their camp with any works whatſoever. But it is evident that the camp of Xantippus, who ſoon afterwards defeated Regulus, and deſtroyed his army, was intrenched as well as that of the Romans. There never perhaps exiſted a general who was more capable than Amilcar Barcas, of chooſing proper and advantageous ground for encampments, or who knew better how to ſecure and defend them. His ſon Annibal, who, though he often ſurpriſed his enemies, was himſelf never once ſurpriſed, always ſecured his camp ſo well with an intrenchment and paliſades, that during the ſixteen years he waged war againſt the Romans in Italy, though he never once diſmiſſed his army from the field, no ſerious attack was ever made on it but on one occaſion by Minucius, when moſt of his troops were out of it a-foraging. As he very judiciouſly adopted the arms and armour of the Romans for his heavy-armed infantry, after the firſt battle he fought with them, it is more than probable that he alſo followed their mode of encamping, in which they appear to have been as ſuperior to any other people among the ancients, as they were in their arms and order of battle. And as ſome part of their method is ſtill retained by all nations in Europe in encamping their troops, it may not be improper or unneceſſary to give a correct plan and deſcription of a Roman camp, and of the diſpoſition or arrangement of its different parts from Polybius, a faithful and judicious hiſtorian, and the only one among the ancients who has left us a diſtinct account thereof. Beſide his ſtrict adherence to truth in all his narratives, he was a perſon of great political and military talents, wrote at a period of time when the government of Rome was in its greateſt vigour, and poſſeſſed a thorough knowledge of all its component parts, cuſtoms, and inſtitutions. This is perhaps the more requiſite, as Juſtus Lipſius, who was a man of much learning, but of little military information, has led almoſt every modern writer wrong, that has treated either on the caſtrametation or order of battle of the Romans.

Though it is highly probable that from the very beginning they ſecured their camps more or leſs with intrenchments, and particularly from the time they began to carry on their operations at ſome diſtance from their own city, and the tribes came to encamp together on the ſame ſpot, or within one and the ſame incloſure, yet if we are to credit ſome hiſtorians, there was but little interior regularity or orderly arrangement of the different parts in them, before the 124th Olympiad, when Pyrrhus, king of Epirus, on the invitation, and in ſupport of the Tarentines, invaded Italy. That prince was certainly endowed both with military talents of an extraordinary nature, and with the moſt undaunted courage; fertile in ſtratagems and expedients, moſt ſkilful in every branch of diſcipline, and perfectly converſant in all parts of the art of war. He waged war with various ſtates, with moſt powerful kings, and great commanders, and generally was victorious without being ever, ſtrictly ſpeaking, vanquiſhed himſelf. In all his battles with the Romans he employed not only the arms but the troops of Italy, and placed, in alternate order, companies of them, and cohorts armed and drawn up after the manner of the phalanx. Even with this contrivance, however, though he rather worſted them in ſome engagements, he never was able to obtain any very clear or decided advantage over them; ſuch were the inherent excellence of their order of battle, and the advantageous nature of their arms and armour in cloſe combat. By their firmneſs and ſteady perſeverance, they at laſt forced him to quit Italy, and leave the Tarentines with the inhabitants of other cities, that had been confederated with him againſt them, to their fate. And getting poſſeſſion of one of his camps, they, from the interior arrangement of it, improved the diſpoſition of their own, and gradually brought their caſtrametation to perfection.

The Romans were the only people we have any account of, who invariably obſerved one mode or manner of encamping, and conſtantly intrenched themſelves wherever they encamped, if they halted only for a ſingle night.

The intrenchments, however, with which they ſurrounded their temporary or large camps in the field were not ſo ſtrong as thoſe which they made round their *caſtra ſtativa*, their forts or ſmaller camps, called *caſtella*, in which a few cohorts or ſmall garriſons were frequently left for ſome time to defend themſelves, without any other aid or aſſiſtance, and which were ſometimes encloſed with two, three, four, and even five or more diſtinct ditches and ramparts.

They had their *caſtra æſtiva*, and their *caſtra hiberna*. The firſt of theſe they occupied in ſummer, when they were carrying on their operations in the field; and the laſt were either towns they took poſſeſſion of, or ſuch as they raiſed themſelves in proper ſituations, and fortified for the purpoſe of quartering their troops in during winter. Their *caſtra æſtiva* were likewiſe of two ſorts, namely, thoſe which they occupied from day to day, or for a ſhort time only, being temporary camps, and called ſimply *caſtra*, and thoſe they occupied for a conſiderable ſpace of time, and which are repeatedly called *caſtra ſtativa*. The former of theſe were more ſlightly intrenched than the latter.

"This, then," ſays Polybius, book vi. "is their (the Roman) kind of caſtrametation.

Ground being always choſen for the encampment, the general's tent occupies the part of it moſt convenient for proſpect and command. A ſtandard being placed where they are to fix it, a quadrangular place is ſo meaſured off round this ſtandard, that all the ſides may be one hundred feet diſtant from the ſtandard, and the area be four acres. See N° 1. in the plan of a Roman camp.

And always before one face and ſide of this figure, which appears the moſt commodious for ſupplies of water and forage, the Roman legions are placed in this manner: there being ſix tribunes, as has been already obſerved, in every legion, and two Roman legions always with each of the conſuls, it is evident, that twelve tribunes of neceſſity ſerve with each of the conſuls. They place, therefore, all their (the tribunes) tents along one right line, which is parallel to the ſide of the quadrangle that has been fixed on, and diſtant from it fifty feet. This place is for the horſes, with the beaſts of burthen, and the reſt of the equipage of the tribunes. See N° 2 in the plan.

Theſe tents being placed with their back parts towards the aforeſaid figure, are ranged fronting outwards towards the ſide, which ſhall always be noticed as, and called by us, on every occaſion, the front of the whole ſcheme. And the tents of the tribunes are equally diſtant from one another to extend along as much ſpace as the whole breadth always of the Roman legions. See N° 3.

The tents of the præfecti of the allies, in like manner, extended the whole breadth of their cavalry and infantry, and had the ſame width of fifty feet behind them for their horſes, beaſts of burthen, and baggage, that was left behind thoſe of the tribunes. See N° 4 and 5, in the plan.

Again, one hundred feet being meaſured off forwards, in front of all theſe tents, they then from the right line, limiting this breadth, which is parallel to the tents of the tribunes, begin to make the camps of the legions, uſing this method. See N° 6.

Having biſected the aforeſaid right line, by a line drawn at right angles to it from this ſtandard, they encamp the horſe of each legion oppoſite to, and fifty feet diſtant from each other, dividing this diſtance in the middle by a line. The arrangement of the tents, both for the horſe and foot, is alike; for the whole figure, both of a maniple and of a troop, is quadrangular. This looks into the ſtreets, and has a determinate length along the ſtreet; for it is one hundred feet. And, in general, they endeavour to give it an equal depth, except for the allies. And when they make uſe of fuller legions, they add both to the length and depth in proportion. See N° 7 and 8.

This encampment then being made of the horſe oppoſite to the middle tents of the tribunes, like a certain ſtreet croſſing the aforeſaid right line, and the place before the tribunes; (for the figure of all the intervals, on each ſide, is, in truth, made like to ſtreets, along ſome of which the maniples, and ſome of them the troops of horſe are encamped); they place behind the ſaid horſe the triarii of both legions, a maniple againſt each troop in the ſame figure of equal length, the figures joining one another, but looking in contrary directions to the oppoſite fronts of the horſe, and make the depth of each of theſe maniples equal to half its length, as their number is always the half only of that of each of the other parts. Wherefore, though the numbers of the men often vary, it happens that all theſe parts are always equal in length by the variation of the depth. See N° 9.

Again, ſetting off fifty feet from each of theſe, they encamp the principes oppoſite to the triarii. And theſe looking towards the ſaid intervals, two other ſtreets are likewiſe formed. But, in the ſame manner as the cavalry, they take their beginnings and commencements from the ſame right line and interval of one hundred feet in front of the tribunes. And they terminate towards that ſide of the intrenchment oppoſite to the tribunes, which, from the firſt, we have ſuppoſed to be at the front of the whole figure. See N° 11.

Next to the principes, and behind them, they, in like manner, encamp the haſtati looking a contrary way, placing the figures cloſe together. And there being ten maniples in each of all the parts, (of a legion) according to the diviſion from the beginning, it happens, that all the ſtreets are equal both as to length, and as to their terminating evenly towards the ſide of the intrenchment at the front, turned towards which they encamp the laſt maniples. See N° 12.

Again, leaving fifty feet from the haſtati, they encamp oppoſite to them the horſe of the allies, beginning at the ſame right line *with them*, and ending at the ſame right line. But, as I have obſerved above, the number of the foot of the allies is equal to that of the Roman legions leſſened by that of the extraordinarii. And that of their horſe is double. A third part being taken from theſe for extraordinarii, by increaſing in proportion the depth of the figures, in which they encamp them, they endeavour to make them equal, as to length, the Roman legions. See N° 14.

All the five ſtreets being now completed, they again, increaſing the depth in due proportion, place the maniples of the allied foot ranging rear to rear to the horſe, and looking towards the intrenchment, and both fronts of its tranſverſe ſides. And in each maniple the centurions occupy the firſt tents on either ſide. See N° 15.

But in following the aforeſaid method of encamping, they ſeparate on each ſide the ſixth troop fifty feet from the fifth, and, in a ſimilar manner, the maniples of foot; ſo that this becomes another opening through the middle of the legions croſſing theſe ſtreets, and parallel to the tents of the tribunes, which they call the fifth, (or via quintana), from its extending along the fifth maniples. See N° 16.

But the place behind and back from the tents of the tribunes lying adjacent to each ſide of the general's ground, becomes one part of it a place for the forum, and the other for the quæſtor, and the things under his charge. See N° 17 and 18.

From the laſt tents of the tribunes, on either ſide, having an arrangement as it were inflected backwards perpendicularly to theſe tents, all the choice men of the extraordinary horſe, and ſome of thoſe ſerving as volunteers, from regard and reſpect to the conſuls, encamp according to (or parallel to) the faces of the intrenchment on the tranſverſe ſides, part of them fronting the ſtores of the quæſtorium, and part of them on the oppoſite ſide looking into the forum. And it for the moſt part happens to theſe not only to encamp near the conſuls, but alſo on marches, and on other neceſſary occaſions, to perform their whole duty and ſervice about the conſul and quæſtor. See N° 19.

And the foot performing a ſimilar ſervice with the forementioned horſe, are placed oppoſite to them, looking towards the intrenchment. See N° 20.

Then from theſe is left a ſtreet one hundred feet wide, and parallel to the tents of the tribunes extending along the oppoſite ſides of the forum, prætorium, and quæſtorium, to the above-mentioned parts of the intrenchment. See N° 21.

And along the upper ſide of this, the extraordinary horſe of the allies encamp, looking towards the forum together with the prætorium, (or general's ground), and the quæſtorium. See N° 22.

At the middle of the encampment of theſe horſe, and at the ſame ground adjoining the prætorium, a ſtreet of fifty feet is left reaching to the rear ſide of the encampment, its direction lying at right angles to the aforeſaid broad ſtreet. See N° 23.

With their backs to theſe horſe again, the extraordinary foot of the allies are placed looking towards the intrenchment and the rear-aſpect of the whole encampment. See N° 24.

And the vacant ſpace left on each ſide of theſe towards the tranſverſe ſides, is given to ſtrangers and allies occaſionally arriving. See N° 25.

All being thus diſpoſed, the whole figure of the encampment becomes an equilateral quadrangle. And as to what relates to the interſection of the ſtreets in it, and its diſtribution in other reſpects, it has an arrangement reſembling a city. They place the intrenchment on every ſide two hundred feet diſtant from the tents; and this vacant ſpace affords them many and great conveniencies. It is commodious and uſeful for the ingreſs and egreſs of the legions. For each of them move out into this open ſpace through their own ſtreets, but do not puſh down and trample on one another by crowding into one. Carrying alſo to this place the booty of cattle they bring in, and the ſpoils they take from the enemy, they keep them ſafe during the nights. But the greateſt is this, that in nocturnal aſſaults neither fire nor weapons, except a very few, can reach them. And it happens, that even theſe are almoſt harmleſs, from the greatneſs of the diſtance, and the ſurrounding tents."

Polybius, in this deſcription of a Roman camp, ſuppoſes a legion to conſiſt of four thouſand two hundred foot, and three hundred horſe. He obſerves, however, that, from it, thoſe who chooſe to examine it will eaſily be able to underſtand the extent and whole perimeter of a camp, even when the legion conſiſts of a greater or leſs number. When more of the allies than are uſual either accompanied them from the beginning of an expedition, or afterwards arrived in the camp, he informs us, that beſides aſſigning to the latter the places already mentioned, they filled with them, alſo, thoſe on each ſide of the prætorium, bringing the forum and quæſtorium together into one place, as the occaſion and neceſſity required; and that as to the former, when their number exceeded what was cuſtomary, beſides the locations uſually made for them, they laid out an additional ſtreet for them beyond the legions both on the right and left ſide of the camp.

But when the four legions and both conſuls were aſſembled together within one and the ſame intrenchment, he ſays, that nothing more is neceſſary for underſtanding their method of encamping than to ſuppoſe two armies diſpoſed of in the manner now deſcribed, with their rears where the extraordinaries as he has mentioned of each were placed, joined together. Whenever this happened, he tells us, the figure of the camp, inſtead of being a ſquare, became a rectangle, having its area double that of the conſular camp he has given a deſcription of, and its perimeter one half greater. This, indeed, is manifeſt, ſince two equal ſquares joined together form a rectangle, of which the area is double that of either, and the perimeter is to that of each of them, in the ratio of 6 to 4 or of 3 to 2. The Romans, he adds, always obſerved this method or diſpoſition as often as both conſuls had their camps joined together, and that as often as they had ſeparate and diſtinct camps, the arrangement continued the ſame, with this variation only, that they then placed the forum, quæſtorium, and prætorium, in the middle between both the armies.

Polybius, in deſcribing the Roman method of encamping, makes no mention of the *velites*, or light-armed troops, who, in every legion, were equal in number to the haſtati, or to the principes. But in giving an account of the compoſition of the legion, and the mode of forming it, he expreſsly affirms, that they were diſtributed equally, or in juſt proportion, among all the reſt, according to their number. It is, therefore, natural to ſuppoſe, that the ſame diſtribution of them exiſted in the camp, or that two-fifths of them encamped with the haſtati, two-fifths with the principes, and one-fifth with the triarii.

From what has been obſerved, then, it appears that the Romans in the time of Polybius, allowed ground for encamping on at the rate of $59\frac{11}{21}$ ſquare feet to every foot ſoldier, and $333\frac{1}{3}$, for every horſeman and trooper and his horſe. For as the haſtati and principes were equal in number in every legion, and the velites equal to each of them, and as each of the former conſiſted of ten companies, amounting, when the eſtabliſhment of the legion was at 4200 foot, to 1200, and had two fifths of this number, or 480 of the velites diſtributed among them, it is evident, that on every ſpot of ground 100 feet ſquare, occupied by a maniple either of haſtati or of the principes, there were encamped 120 of themſelves, and two fifths of this number, or 48 of the velites, in all 168 men. But a ſquare, of which the ſide is equal to 100 feet, contains 10,000 ſquare feet, which divided by 168, gives 59 ſquare feet, and eleven twenty-one parts of a ſquare foot. In like manner, as the number of the triarii was only equal to half that of either the haſtati or the principes, amounting to no more than 600 men, and as theſe were alſo divided into ten companies, and had one fifth part or 240 of the velites diſtributed among them, it is manifeſt, that on each of the ten rectangles, occupied by their maniples, there were encamped 60 of themſelves, and 24 of the velites, or 84 men. But a rectangle 100 feet long and 50 feet broad, contains 5000 ſquare feet, which divided by 84 gives likewiſe 59 ſquare feet and eleven twenty one parts of a ſquare foot.

We arrive at the ſame concluſion by dividing the number of ſquare feet contained in the whole ground aſſigned by Polybius for encamping all the foot of a legion, by 4200, the number of them. For the haſtati and principes encamped on 20 equal ſquares, of which each contained 10,000 ſquare feet, having its ſide equal to one hundred feet. The whole 20 then, of courſe, contained 200,000 ſquare feet. If to this number of ſquare feet there be added the contents of the ten equal rectangles of 5000 ſquare feet each, that were occupied by the ten maniples of triarii and their proportion of velites, or 50,000 ſquare feet, we get 250,000 ſquare feet for the ſurface of the whole ground, that the infantry of one legion encamped on, which number of ſquare feet divided by 4200 give 59 ſquare feet, and eleven twenty-one parts of a ſquare foot as before.

And as there were 300 horſe then in each legion, who were alſo divided into ten parts or troops, and encamped on ten equal ſquares of 10,000 ſquare feet each, it is no leſs evident that the encamping ground allowed for them was at the rate of 333 ſquare feet, and one third part of a ſquare foot for each horſeman or trooper and his horſe, ſince 10,000 divided by 30, or 100,000 divided by 300, give, 333 and one third.

Polybius alſo informs us that the excavation of the ditch and the raiſing of the rampart along the two tranſverſe ſides of the intrenchment, or thoſe near the wings of the allies, were done by them, and that the other two ſides were left to the Romans, to each legion one; that each ſide was divided into as many parts or portions as there were maniples to labour on it, and a centurion appointed to ſuperintend the execution of the work in each part, and that the whole ſide was inſpected and approved of by two of the tribunes, whoſe turn of duty it was to attend to every kind of neceſſary ſervice in and about the camp. For the tribunes, two by two in rotation, took upon them not only the care of the camp, but the management and direction of every thing done in it for two months at a time.

As in encamping, a place was fixed for the conſul's or general's tent before ground was laid out for any others, ſo on breaking up the camp, his tent and thoſe of the tribunes were always firſt taken down. And when they were all ſtruck, the baggage collected and placed on the beaſts of burthen, the whole camp on a ſignal made began to move, with the extraordinaries uſually in the van, and next to them the allies of the right wing, followed by the baggage of both. Next to them marched the firſt of the Roman legions with its baggage behind it; then followed the ſecond legion, having behind it not only its own baggage, but alſo that of the allies of the left wing, who cloſed the rear of the whole march.

Polybius in his deſcription of a conſular camp has not given us any dimenſions for the rampart and the ditch. Theſe muſt have varied with circumſtances and ſituations, and particularly with the length of time for which it was intended to be occupied. Julius Cæſar in the ſecond book of his war in Gaul, chap. v. informs us that he ordered one of his camps to be ſecured with a rampart 12 feet high, and a ditch 18 feet deep.

In deſcribing the Roman camp, Polybius does not give us either the names or number of the gates. He only informs us, that the exterior ſides of the camp were guarded at night by the velites, who placed ten of their number at every gate, and kept watch alſo in the day-time throughout the whole extent of the intrenchment. It is well underſtood, however, from the information left us by other hiſtorians, that there were four principal gates, viz. one in the middle of the front of the intrenchment oppoſite to the termination of the ſtreet of fifty feet wide between the cavalry of the Roman legions, another directly oppoſite to it in the middle of the rear of the intrenchment, and two directly oppoſite to each other, and to the ends of the ſtreet of 100 feet wide between the tents of the tribunes and the Roman legions in the tranſverſe ſides of the intrenchment. That one of the two laſt mentioned, which was on the right hand ſide of the camp, was called *porta principalis dextra*, and the other on the left hand ſide, *porta principalis ſiniſtra*. The other two principal gates, namely the two firſt mentioned, were called *porta prætoria* and *porta decumana*. But in regard to their real or actual ſituations, though all writers on the ſubject allow them to have been oppoſite to each other, doubts and different opinions have ariſen, ſome placing the decuman gate in the front ſide of the intrenchment and others in the rear. Thoſe, who contend for its having been placed in the middle of the rear ſide of the intrenchment, make it derive its name from this circumſtance, that ſuch of the ſoldiers, as had been found guilty of neglect of duty or delinquency, were conducted through it to the place appointed for their puniſhment or execution, and refer to the following words of Vegetius, book i. chap. 23, "Porta autem, quæ appellatur prætoria, aut orientem ſpectare debet, aut illum locum, qui hoſtes reſpicit; aut ſi iter agitur, illam partem debet attendere, ad quam eſt profecturus exercitus, intra quam primæ centuriæ, hoc eſt, cohortes papiliones tendunt, et dracones et ſigna conſtituunt. Decumana autem porta, quæ appellatur, poſt prætoriam eſt, per quam delinquentes milites educuntur ad pœnam.

The late major general Roy referring to this paſſage expreſſes himſelf in theſe words: "With regard to the decuman gate mentioned in this paſſage of Vegetius, it is to be obſerved, that for the maintenance of that rigorous diſcipline eſtabliſhed in the Roman armies, when a particular corps or any number of ſoldiers had miſbehaved in the field, or had been mutinous to their officers, it became neceſſary to decimate the delinquents, every tenth man being drawn out by lot and doomed to ſuffer death. Hence we may judge, that the decuman gate had its name from thoſe, who had received ſentence, being led out by it for puniſhment or execution." Military Antiquities of the Romans in Britain, page 50.

It does not follow, however, from the foregoing words of Vegetius, that delinquents were led out through the gate in the rear of the camp to receive puniſhment. It may juſt as well be inferred from them that they were carried out through the gate in the front of the camp. And from his obſerving that the prætorian gate ought to look either towards the eaſt or the enemy, we cannot exactly aſcertain whether it was cuſtomary for the Romans to make the front or rear of their camp look towards the eaſt. But this inference may reaſonably enough be drawn from them that the prætorian gate ſometimes looked towards the enemy and ſometimes not. Polybius, without making the four different aſpects of his conſular camp have any reference whatſoever to the eaſt, weſt, north, and ſouth, expreſsly ſuppoſes the front of it to look towards thoſe parts, that were moſt convenient for ſupplies of water and forage. If any one of the principal gates in his time went by the name of porta decumana, it was probably ſo called from the decumani manipuli, and decumanæ turmæ next to the front of the intrenchment. That it took its name from ſoldiers ſelected by decimation for puniſhment, being led through it out of the camp, is a ſuppoſition directly contrary to his authority; for he informs us, when ſpeaking of that puniſhment and the rigour of the Roman diſcipline, that it was actually inflicted within the camp.

Lipſius, whom moſt of the modern writers on the Roman caſtrametation as delivered by Polybius have followed, though a man of great learning, departs from ſome of the rules laid down by that hiſtorian. He leaves out the ſpace fifty feet wide between the ground, that was occupied by the tents of the tribunes, and the forum, prætorium, and quæſtorium, which Polybius expreſsly aſſigns for their horſes, beaſts of burthen, and other equipages, in theſe words, ἵπποις ἅμα δ᾽ υποζυγίοις καὶ τῆ λοιπῆ των χιλιαρχων αποσκευῆ τοπος. Now that their tents were not only in front of this ſpace, but alſo at ſome little diſtance from it, is evident from another paſſage in this hiſtory, where he informs us, that three companies were allotted to each tribune, who, among other ſervices they performed for him, furniſhed him always with a double guard, conſiſting of four ſoldiers, two of whom were ſtationed before his tent, and the other two behind it near to the horſes.

He allows, however, 50 feet in depth as we have done, for the tribunes' quarters; and this depth does not appear to be more than what was neceſſary for them, excluſive of the 50 feet allowed for their horſes, beaſts of burthen, &c. as they were the officers next in rank and dignity to the conſul and quæſtor, had, two by two in ſucceſſion, charge of the whole camp, and the ſuperintendance of every thing done in it, and had alſo all delinquents brought before them to be tried and to receive ſentence.

Although he leaves out the aforeſaid width of 50 feet left for the horſes, &c. of the tribunes, he quarters among the guards a number of volunteers, ſo greatly exceeding that which uſually attended one conſul, with two legions and the ordinary complement of allies, that he makes his camp 33 feet longer from front to rear than it is broad, contrary to the rule for keeping it always an equilateral quadrangle. In this particular, then, he departs not leſs than 83 feet from the rules laid down by Polybius, and makes the ground for quartering or encamping the extraordinarii in the rear deeper by the ſame number of feet than by theſe rules it could be.

Inſtead of making the quarters of the guards for the conſul and quæſtor commence, according to Polybius, from the laſt tents of the tribunes, or from the quæſtorium and forum, which extended on the right and left of the prætorium towards the tranſverſe ſides of the camp as far as the encamping ground of the tribunes, and that of the Roman legions did, he makes them begin 20 feet diſtant from the ſame.

Though Polybius neither mentions the præfecti of the allies, nor aſſigns any encamping ground for them, it is natural to ſuppoſe, that their quarters, like thoſe of the tribunes, extended the whole breadth of their own horſe and foot, and no farther, leaving a paſſage 50 feet wide between the laſt tent of the tribunes and the firſt of theirs, both on the right and left, which paſſages muſt have been very convenient as communications with the principia for the horſe guards, who fronted the forum and quæſtorium. Lipſius, however, makes the tents of the præfecti extend 29 feet into each of theſe openings, beyond the encamping ground of their own troops.

He alſo takes up ground for the quæſtor and two legati excluſive of that for the public, which he has no authority for from Polybius, who makes no mention at all in his account of the Roman caſtrametation of a legatus or legati.

As to the duke of Rohan's plan of a Roman camp, he leaves out with Lipſius the ſpace acroſs it 50 feet wide, expreſsly allowed by Polybius for the horſes, beaſts of burthen, baggage, &c. of the tribunes. He makes the ground for quartering the ſupernumeraries, ſtrangers, and part of the extraordinary, too deep by 50 feet, which additional depth being equal to the width of the ſaid ſpace left out behind the tribunes' tents, cauſes his plan to be a ſquare, though in his diſtribution of theſe quarters, he entirely miſtakes that hiſtorian's meaning. He alſo lays out the quæſtorium in various whimſical diviſions without the leaſt ſhadow of authority from that writer.

Sir Henry Saville, in his view of the military affairs of the Romans, gives a deſcription of their conſular camp, which he makes a ſquare or equilateral quadrangle, but 32 feet broader and deeper than it ought to be, by allowing the horſe of the allies 16 feet more depth on each ſide than their juſt proportion. He, in like manner, leaves out the ſpace 50 feet wide allowed to the tribunes for their horſes, beaſts of burthen, and baggage; but makes the encamping ground for the extraordinary that remain after thoſe ſelected for the guards are taken from them, and for ſtrangers and ſupernumerary allies, too deep by 82 feet, which being equal to the 50 and 32 feet juſt mentioned, conſtitutes the Roman camp as deſcribed by him a ſquare, of which the ſide, however, is 30 feet longer than it ought to be according to Polybius. He alſo makes the quæſtorium and forum too large, and the quarters of the guards too ſmall. He likewiſe gives the encamping ground of the præfecti of the allies an extent of 50 feet more than that which their own horſe and foot cover.

The late major-general Roy has profeſſedly given us a plan and deſcription of a conſular camp, and alſo a plan of a Roman camp, when both conſuls encamped together, or within the ſame intrenchment, in his military antiquities of the Romans in North Britain, publiſhed after his death in one volume in folio by the Royal Society of Antiquaries in 1793. But not being acquainted with the Greek language, he took the accuracy of Mr. Hampton's tranſlation of Polybius for granted, as he himſelf informs us, ſuppoſed with him the cavalry of the allies to have been triple that of the Romans, and on that erroneous ſuppoſition has grounded all his computations reſpecting their caſtrametation, and particularly in comparing the Polybian camp with thoſe in Scotland, that were firſt diſcovered by the learned, ingenious, and very able military antiquarian, general Melville, in 1754, who manifeſted a very fine and ſuperior degree of diſcrimination in concluding from Tacitus's narrative, and the reaſons of war, that Agricola muſt have croſſed the Tay above Perth, and proceeded along Strathmore, and that there were certainly ſome remains of his camps ſtill to be found in that vale, in oppoſition to the opinion of the engineers, who were then employed by government on a ſurvey of that country, and the perſevering aſſertions of one of them in particular, who had actually ſurveyed the ſituations, on which they were afterwards diſcovered by general, then captain, Melville, without knowing what they were. General Roy received from captain Melville, who was about to leave this country and repair to the Weſt Indies, a communication of that diſcovery, and firſt learnt from him, as he himſelf acknowledges, what was really meant by a temporary Roman camp, which information excited his curioſity, and led him to turn his attention to the ſubject of Roman military antiquities in Great Britain. But though he proſecuted it occaſionally for a number of years with a very laudable degree of zeal and induſtry, it muſt be allowed, that he committed ſeveral material and great miſtakes in his plan and deſcription of the Polybian conſular camp.

He leaves out the ſpace fifty feet wide behind the tents of the tribunes, expreſsly allotted by Polybius for their horſes, &c. He does not make the extent of the tribunes encamping-ground tranſverſely acroſs the camp, ſo great as that of the Roman horſe and foot, by about one hundred and fifty feet, leaving a diſtance of about two hundred feet between their firſt tents on the right and left; whereas Polybius tells us, that the one was equal to the other. His words are theſe: ἀφεϛᾶσι δ' ἀλλήλων μὲν ἴσον αἱ τῶν χιλιάρχων σκηναὶ, τοσοῦτον δὲ τόπον ἄϛε παρ' ὅλον τὸ πλάτος ἀεὶ τῶν Ῥωμαικῶν ϛρατοπέδων παρήκειν.

He leaves an open place or ſtreet of twenty five feet wide on the left of the prætorium, between it and the forum; then ſets off a rectangular ſpace of the ſame depth with the prætorium, and about one hundred and thirty feet wide, which he divides equally into two parts, the one next to the tents of the tribunes as quarters for the legati, and the other immediately behind that for the market-place, or forum; then leaves another ſtreet of twenty five feet wide; and on the remainder of the ground ſet apart by Polybius for the forum, extending as far as that occupied by the laſt tent of the tribunes on the left he encamps one half of the ablecti, or ſelect horſe of the allies for the conſul's guard. He then leaves a ſtreet fifty feet wide, making that between the haſtati and horſe of the allies on the left extend quite to the rear of the camp, then encamps half the evocati and volunteer horſe looking toward the prætorium, and cloſe behind them, with their backs to theirs, half the evocati, or volunteer foot; then leaves another ſtreet of twenty-five feet, and beyond that encamps half the ſelect foot of the allies for the conſul's guard. On the right of the prætorium, he in like manner leaves a ſtreet twenty five feet wide, then ſets off a rectangular ſpace as deep as the prætorium, and about one hundred and thirty feet broad for the quæſtor's quarters, and for the cloathing, arms, and proviſions behind them; then leaves another ſtreet twenty five feet wide; then encamps the other half of the ablecti, or ſelect horſe of the allies for the conſul's guard; and ſo on as on the left. In making all theſe ſtreets, diviſions, allotments, and allocations, he is ſo far from being ſanctioned by Polybius, that they are in direct repugnance and contradiction to that author's authority, who makes no mention at all of legati, but allows about five times as much ground for the forum, and about twice and a half as much for the quæſtorium as he does.

On each ſide of the ſtreet fifty feet wide, leading to the rear from that of one hundred feet in width behind the prætorium, he allots a rectangular ſpace of four hundred feet by one hundred and twenty five for the extraordinary horſe of the allies facing the ſaid broad ſtreet, and an equal ſpace on each ſide for the extraordinary foot of the allies immediately behind them and facing the rampart; then leaves on each ſide a ſtreet fifty feet wide, and laſtly makes two rectangular locations of four hundred feet by two hundred and fifty each for ſtrangers coming to the camp, thus prepoſterouſly allowing for occaſional comers, as much ground as he allots for the encampment of all the haſtati and principes, with four fifths of the velites of a complete Roman legion. The truth indeed is this: he makes the depth of the encamping ground in the rear of the prætorium one hundred and eighty three feet, and one third of a foot greater than it ought to be by Polybius's account of the Roman caſtrametation. And his camp taken altogether differs widely and eſſentially from the one deſcribed by that author. For he makes each ſide of the encampment one hundred and thirty three feet, and one third of a foot longer than it ſhould be, and each ſide of the intrenchment alſo of courſe. Of this, he ſeems to have been partly aware himſelf; for in page 45 of his work, when he uſes in the text theſe words, "therefore the ſide of the ſquare of intrenchment of a conſular army was two thouſand one hundred and fifty Roman feet," he in a note expreſſes himſelf in the following: "If according to Lipſius and others, who have copied from him, there had only been in the conſular camp twice the number of *allied foot* (he muſt unqueſtionably have meant to ſay *allied horſe*) that there was of Roman horſe, then the ſpace actually occupied by the troops would have been a ſquare of ſixteen hundred and ſixteen Roman feet, and two thirds of a foot." It is much to be regretted that there are many palpable errors and miſtakes in that elaborate, and in many reſpects valuable performance, which might have eaſily been avoided by a little proper attention to the printing of it. They are ſo numerous indeed, that we cannot allow ourſelves to regard it as a correct copy of the manuſcript, he left behind him.

The ſquare was the moſt convenient and beſt figure the Romans could have adopted for their encampments. Of all right-angled quadrilateral figures of the ſame perimeter, its area is a maximum, or the greateſt. It therefore required leſs extent of intrenchment than a rectangle of the ſame area or ſuperficial contents. And if we examine the diſpoſition or arrangement of the various locations they made within it for their troops, taking into conſideration at the ſame time the invariable ſimplicity and regularity of their method of encamping, we ſhall find, that there neither was any ground loſt nor any wanted to render it more commodious, and be apt to regard it as the beſt perhaps, that could have been contrived before the invention of gunpowder, and the uſe of fire-arms, which have made great and eſſential alterations neceſſary.

Even in modern encampments, however, ſo much of the Roman method is ſtill retained by all nations, that in encamping their troops, they conſtantly place the privates in the front, behind them the ſubalterns, then the captains, and in the rear of theſe the field-officers. And Frederick the Great, king of Pruſſia, tells us, that it was his cuſtom, in imitation of the Romans, to encloſe his camps with intrenchments, which, beſides anſwering other good purpoſes, contributed greatly to prevent deſertion.

We ſhall now proceed to give an account of modern caſtrametation, which is alſo regulated, in a great meaſure, by certain rules, that are liable, however, to be altered and varied in different ſituations and poſitions, ſo as to occupy the ground to the beſt advantage, and moſt commodiouſly for the free and uſeful operations of the different deſcriptions of troops, according to the opinion and judgment of the general, or officer commanding them.

Camps take different names, or denominations, from the objects thoſe have in view who form them; ſuch as for inſtance:

Camps offenſive,
Camps defenſive,
A camp of rendezvous,
A camp of paſſage,
A camp of reſt or repoſe,
A fixed or ſtanding camp,
A flying camp,
A camp of peace and exerciſe,
A camp for forage,
A camp of obſervation,
A covering camp,
An entrenched or retrenched camp.
An entrenched or retrenched camp in a campaign, or open country.

*Camps offenſive*, or camps for the attack, interruption, and annoyance of an enemy.

The principal objects which every general either has, or ought to have in view when he chooſes ground for a camp, are of two kinds, the one offenſive, and the other defenſive. The camp in which an army aſſembles, at the beginning of a war or the opening of a campaign, is of the firſt claſs or deſcription. In ſuch camps, attention ought chiefly to be paid to the convenience of the troops, who ſhould encamp in ſmall ſeparate corps near their magazines, or depots, in ſuch a manner, as to be able to unite in a ſhort time. And as ſuch camps are generally at ſome diſtance from the enemy, there is little or no danger to be apprehended from making the convenience and accommodation of the troops the firſt object of attention.

The moſt eſſential properties of every camp are health, fulneſs, and ſecurity. Theſe are advantages which ought to be attended to and ſought after on all occaſions. But an attention to wholeſomeneſs is ſtill more neceſſary in one that is to be occupied for a conſiderable length of time, than in another, where troops are to make but a ſhort ſtay. Low, wet, damp, and marſhy places ſhould be avoided in every country; and in hot climates, ſituations that are much expoſed to the burning heat of the ſun. On the other hand, riſing grounds with an eaſtern aſpect, commodiouſly ſituated for paſture, and for ſupplies of water, forage, and fuel, ought to be preferred to other ſituations for encampments.

A general ought to be a good judge of ſituations himſelf, and to chooſe his own camps. His knowledge ſhould not, as is ſometimes the caſe, be confined to the mere rudiments of the art of war, or to the fiddle faddle buſineſs of parades, reviews, and ſham fights, that have no reſemblance whatever to real actions. He ſhould be able to diſcern at ſight, or to diſcover with a glance of his eye, all the poſſible advantages, as it were, which any poſt or poſition is capable of affording, and to improve this talent in practice, by the principles of fortification, which are the baſis, or ground-work of it, and which he ought to carry with him into the field, and apply to every ſituation of his army, availing himſelf of heights, defiles, rivers, rivulets, moraſſes, inundations, woods, &c. When maſter of the rules of that ſcience, he can alſo apply it ſucceſsfully for finding out the weakneſs of the enemy's poſition and order of battle.

*A camp offenſive*, or of offence, is formed for the purpoſe of annoying an enemy in various ways, ſuch for inſtance, as to force him to raiſe a ſiege by cutting off, or ſtraightening his intercourſe with the adjacent parts of the country and his own depots; to compel him to quit an advantageous poſition by either attacking it at laſt if neceſſary, or by inveſting one of his towns or places; to make incurſions into ſome one or other of his provinces; to intercept his convoys; to embarraſs his communications; to conſume the forage he might draw benefit and advantage from; &c.

As ſecurity is always one of the firſt objects of conſideration, every camp, of whatever ſpecies or deſcription it may be, ought to have its front and flanks placed entirely out of the reach of inſult. In any ſituation, therefore, that is choſen or fixed on for a camp, (and there are various ways of occupying the ſame ground) care ſhould be taken not to extend either flank towards the enemy, or to expoſe it to commanding ground within cannon-ſhot, that he may have it in his power to occupy or poſſeſs himſelf of, but to place it in ſuch a manner as to make it afford ſupport to both wings of the army. It ought to be guarded and ſecured both in front and rear by detachments; and particular attention ſhould be paid to its lying commodiouſly for paſture, forage, water, and wood, which is not only uſeful as fuel, but for pickets, paliſades, and other purpoſes. It ſhould alſo be conveniently ſituate for the army that occupies it, to move out of it either to form in order of battle, or to abandon it altogether without being expoſed to much moleſtation from the enemy, who, did he command the principal avenues or approaches to it, would have it in his power to ſhut them up, and thereby force them either to ſurrender, or to attack and fight him on very diſadvantageous terms. There are many ſituations that appear to be very ſtrong, and naturally are ſo, which, from this very circumſtance of troops not being able to quit them when neceſſary without expoſing themſelves, are in reality both weak and dangerous. And an unſkilful general may be led by the mere appearance of them into great miſtakes, and thereby, not only draw diſgrace on himſelf and his troops, but alſo plunge his country into the moſt diſaſtrous calamities. But a knowledge of fortification will enable a commander of naturally good talents to chooſe heights, and occupy them in ſuch a manner, as to prevent their being commanded by others; to cover his flanks effectually, ſo as to ſecure each poſt as to render it capable of defence, and to avoid thoſe, in which a gallant officer cannot maintain his ground, without running the riſk of loſing his reputation.

*Camps defenſive*, or camps of defence. Such camps are ſtrong by their ſituations chiefly, and have no other deſign than that of preventing attacks. Every ſituation that has its front and flanks equally ſtrong, and is free and open behind, is proper for this ſort of camps. There are heights that have a front of a certain extent, and their flanks covered by moraſſes, and poſitions, that are ſecured in front by a river or marſhy rivulet, and their flanks by ponds. Such camps having no other object than to prevent their being attacked by the enemy, great care ſhould be taken not to fix on falſe points of ſupport. For this purpoſe, the rivers and marſhes in their front, and on their flanks, ought to be ſounded in order to aſcertain whether the rivers are not fordable, and the marſhes impracticable.

When ſuch a camp has a river in its front, it ſhould not be placed nearer to the bank thereof than eight hundred or a thouſand paces, in order to leave ground ſufficient for drawing up the army in order of battle.

Poſitions taken under the protection of towns or places, are defenſive camps.

When the object of a defenſive camp is to cover a country, the principal attention of a general in chuſing it ought to be directed to thoſe points, which the enemy has it in his power to attack, and by which he might penetrate.

*Camp of rendezvous*. When at the commencement of a war, or the opening of a campaign, an army is brought together in the field, either in one entire body, or in a ſeparate corps, or parties, at no great diſtance from one another, it is ſaid to be in a camp of rendezvous. Such a camp is either more or leſs out of the reach of the enemy, and in the firſt of theſe caſes the convenience of the troops ought to be the firſt object of attention. It is alſo ſometimes intended to be offenſive, and ſometimes defenſive. When it is formed for the purpoſe of offenſive operations the following maxims ought to be obſerved:

To avoid extending either flank towards the enemy, or expoſing it to ground that he can take poſſeſſion of; to chooſe a poſition for it ſtrong by nature; to ſupport well the wings; and to ſecure it againſt ſurpriſe or any ſudden aſſault by detachments, both in front of, and behind it.

To proportion its extent to the ſtrength of the army.

If you are in an open and level country, to encamp your army in order of battle, and if you cannot ſecure your camp againſt inſult or ſurpriſe by detachments, to throw up intrenchments ſufficient to prevent your being obliged to fight contrary to your intention or inclination, or when it is not neceſſary for you to come to action.

In a broken or uneven country, to ſeparate your army without encamping the different corps at too great a diſtance from one another, occupying the highways, villages, &c. in your front.

In a mountainous country, to encamp your troops according to the ſituation and nature of the ground, but in ſuch a manner that the moſt advanced corps may receive prompt aid and ſupport from the reſt.

Not to place your cavalry on either wing when it is near a wood, village, or other place, into which the enemy can throw in ſome of his infantry; but ſometimes to place them all on one wing, and ſometimes to encamp them in a ſecond line, or otherwiſe, as the ground and circumſtances may point out.

When the enemy is on the oppoſite ſide of a river, rivulet, moraſs, &c. to encamp at a ſufficient diſtance from it to prevent your being incommoded by his fire, in even forming your army in order of battle in front of your own camp.

To reconnoitre the highways, rivers, riſing grounds, rivulets, ferries, caſtles, woods, and other places in the neighbourhood of your camp; and to keep open a communication between its rear and ſeveral roads, for the purpoſe of receiving ſupplies of proviſions, &c.

To chooſe your camp in ſuch a manner, that the enemy, by moving on his right or left, may not oblige you to quit your poſition, but on the contrary, that by making a ſhort or ſmall movement yourſelf you may compel him to make a long or circuitous one, and to quit his poſition or leave the country.

This is the ſureſt criterion by which one can judge of the ſkilful or unſkilful choice of a camp.

And, in ſhort, though you are acting offenſively, to take every poſſible precaution for the ſecurity of your camp when the enemy is near you, and by no means to deſpiſe him. For negligence and contempt of an enemy tend always to render him bold and enterpriſing.

When defenſive operations are the object of a camp of rendezvous, it is neceſſary to obſerve, beſides theſe, the following maxims:—

To avoid encamping in a plain or level country.

To attend particularly to the extent of the ground you occupy, and to the number and nature of the troops your army is compoſed of.

Always to entrench your camp, taking care that no part of it can be enfiladed.

To occupy the bridges and fords of rivers, &c. and if you are apprehenſive of ſuffering by inundations, to make dikes to turn the courſe of the water.

To avoid placing either of your wings behind a moraſs, or any thing elſe, that may be an obſtacle to its manœuvring eaſily, and co-operating with the reſt of your army in caſe of an attack.

To place your artillery on heights, and diſpoſe of it in ſituations from which it can do moſt execution.

And to keep open a free and convenient egreſs from it in the rear, that your retreat may not be cut off.

*A camp of paſſage.* In an offenſive war troops encamp tranſiently, when they march either to attack an enemy, or to diſlodge or force him from a poſt, by different manœuvres; or to get before him to ſome paſſage, and penetrate into his country ; or to inveſt a place, and form the ſiege of it ; or, in ſhort, to join an advanced corps or army.

In a defenſive, as well as an offenſive war, they occupy a camp of paſſage when they take poſt to cover their country; when they are obliged to regulate their movements by thoſe of their enemy ; when their object is to effect ſome junction; or, finally, when they are conſtrained to abandon a poſt, a frontier, or even one part of their country to cover another.

*A camp of reſt or repoſe*, is that in which troops either wait for forage, or watch the enemy's motions, in order to regulate theirs by his, or in which they are allowed to remain for ſome time ſtationary on account of ſickneſs or ſome other cauſe. As repoſe is the ſole object in ſuch a camp, it ſhould have ſuch a river or moraſs in its front as renders it inacceſſible. And if the river, rivulet, or moraſs in front of it has not a ſufficient depth of water it ſhould be dammed up ſo as to be impaſſable.

Such a camp ſhould not only have its front naturally ſtrong, but alſo have a ſite or ſituation that is elevated and healthy ; and when it is of a permanent nature, it ſhould have abundance of water, wood, forage, and proviſions, within its reach and command, and ſhould cover the road or route of all its convoys.

*A fixed or ſtable camp* may have different objects, according as an army acts offenſively or defenſively.

When it is on the offenſive, it occupies ſuch a camp for a certain time, to form the ſiege or blockade of a place ; to wait the effect of a diverſion or the capture of a place, which a detached corps has been ſent to attack ; to give a reinforcement or convoy time to arrive ; to conſume or deſtroy, during the courſe, or towards the end of a campaign, the forage or ſubſiſtence of a country, which they deſign to abandon ; to give reſt or repoſe to an army after a long march or operation that may have cauſed a loſs of men, or occaſioned diſeaſes, or, in fine, during the courſe of a campaign, that has not been ſo proſperous or fortunate as was at firſt expected.

When a general encamps before a place to attack it, which he knows the enemy cannot aſſemble a ſufficient force to attempt the relief of, and when he has little to fear from any detachments he may ſend out, either for that purpoſe or to interrupt the operations of the ſiege, he has then only to diſtribute his troops round the place as commodiouſly as he can, ſeizing on commanding grounds and other advantageous objects, and taking care to have his circumvallation as near to it as poſſible, provided he is juſt out of the reach of annoyance from the beſieged's ſhot and ſhells.

When he is on the defenſive, he chooſes a ſtable camp to cover his country, or ſome place of importance, that the enemy deſigns to beſiege. Beſides theſe two objects, a ſtable camp has ſeveral others, which are common to it with camps of other denominations. There is one, however, which it may not be improper to mention, which is this, that a general can remain in it till he ſees his enemy ſeparate his forces, and ſend them into winter quarters, in order that he may go into his own without dread of diſquietude or moleſtation.

*A flying camp* denotes a corps or body of troops conſiſting of three, four, five, ſix, &c. thouſand men, infantry and cavalry, that has power to encamp and decamp at the pleaſure of the general or officer commanding it, as neceſſity and circumſtances may require, that is continually in the field, and is conſtantly making divers movements to haraſs the enemy, ſtop his incurſions, check and render abortive his enterpriſes, intercept his convoys, teaze and fatigue the neighbouring country, and to throw itſelf, in caſe of need, into a beſieged place, that is in want of ſuccour or aſſiſtance.

Though there is ſome difference between the command of a flying camp and a large army, the reſemblance, however, is ſo great, that a general officer, who has often commanded a detached or ſeparate body of troops is, *cæteris paribus*, fitter for the command of a large army than one who has not enjoyed that advantage.

A general officer, therefore, who is ambitious of preferment, anxiouſly endeavours to procure for himſelf ſuch commands and to qualify himſelf for them.

A flying camp occaſions much uneaſineſs and diſquietude to an enemy, by hovering on his wings. It is deſtined to cover ſome tract of country between two armies ; to make head againſt ſome ſimilar corps, that the enemy has formed or detached ; to undertake and execute ſome particular enterpriſes ; to throw troops into ſome place that is menaced or threatened ; to draw contributions from certain diſtricts, and to regulate its movements at the ſame time, in ſuch a manner as always to have it in its power to join the main army after a march of one or two days at moſt, in order that, if a favourable opportunity for a general engagement ſhould preſent itſelf, it may arrive in time to take a ſhare in it.

The general, who commands a flying camp, ought to be extremely attentive and vigilant, to have his troops highly diſciplined, to ſuffer no ſtraggling or diſperſion of them, to march with great precaution, to chooſe advantageous camps, and to regulate his movements in ſuch a manner as to be always in readineſs to ſurpriſe his enemy when it is poſſible, without running the riſk of being ſurpriſed himſelf. He ſhould be alert againſt all ſorts of enterpriſes on the part of the enemy. He ought to have parties always on the look out, and to relieve them ; and he ſhould not be ſparing in the employment of ſpies, of whom he may have enough if he only pays them well. Money can ſeldom be more uſefully employed.

*A camp of peace and exerciſe*, is a camp deſtined for the exerciſe of all the military duties and functions.

In ſuch peaceable encampments the troops ſhould be trained up and inſtructed in every ſort of fatigue, labour, and duty, which is neceſſary on actual ſervice, for rendering warfare ſucceſsful. In ſuch a ſituation an active and able general will not only have them practiſed in throwing up works expeditiouſly, but will alſo turn a great part of his attention to their diſcipline. He will make them encamp in order of battle, and cauſe every part and branch of the ſervice to be performed with as minute accuracy, and as punctual an obſervance of orders, as if they were in the field, or in the face of an enemy. He will examine whether the officers on guard are ſufficiently vigilant and acquainted with every particular of their duty, and whether the guards themſelves are poſted according to orders. He will not only have the infantry exerciſed frequently, but the cavalry alſo, when they are not employed in foraging, and the recruits of both daily. He will inſpect and look at the horſes himſelf, praiſing thoſe officers, who have been careful of them, and ſeverely reprimanding thoſe who have neglected to have them taken care of. In ſhort, he will by his vigilance and attention, in making every part of his army perform its duty with punctuality and exactneſs, give activity, ſkill, and animation to the whole, and prepare them for acting with vigour, advantage, and ſucceſs againſt an enemy.

*A camp of forage, or for foraging.* Such camps are ſometimes at a diſtance from and ſometimes near to the enemy. In the firſt caſe, neither your camps nor foraging parties are in danger of moleſtation or inſult. There are certain precautions, however, that ought never to be neglected, even when you have nothing to apprehend from any attempts of the enemy. Your camps therefore ought, in either caſe, to be ſtrong by nature, or rendered ſo by art, and particularly in the laſt, when you are near to an enemy. Beſides, a ſtrong camp enables you to ſend out ſtronger foraging detachments than you could otherwiſe venture to do; and on this ſervice it is ſometimes neceſſary to employ a great part of your army. Foraging is certainly an eſſential part of the art of war; and parties of foragers may very juſtly be conſidered as detachments ſent out againſt the enemy. A rich and fertile tract or diſtrict of country ſhould be choſen for it, and ſecrecy ought to be obſerved in regard to the time when, and the place where, you intend to forage. Your orders reſpecting this ſervice ſhould not be communicated even to the officer, who is to command the troops employed on it, till late in the evening before it is to be performed. You ought, on ſuch occaſions, to detach a number of ſmall parties to acquire an exact knowledge of the enemy's motions. And, if you are on your guard againſt ſtratagems, it will be ſafer for you to forage when he does than at other times.

*A camp of obſervation* is the camp of an army employed in watching the motions and operations of an enemy, in haraſſing and perplexing him, and preventing him from penetrating in a country or tract of territory, to ſurpriſe or take an important place, or to moleſt another army, and force it to abandon its preconcerted enterpriſes and deſigns. An army of obſervation, during a ſiege, is almoſt always in motion and on the look out, occupies the avenues or approaches by which the enemy can preſent himſelf, follows him in his movements, keeping parallel to him, but conſtantly between him and the beſieging army, in the moſt advantageous manner it can, to avoid being obliged to fight contrary to its inclination, and ſometimes ſeizes on a commanding poſt, and there entrenches itſelf, when its camp may be called.

*A covering camp,* which appellation is given both to ſuch an encampment for covering a ſiege, and to poſitions choſen for camps that are deſigned to cover a country or diſtrict. In chooſing one for the laſt of theſe objects it is not neceſſary to pay ſo much attention to the natural ſtrength of the place itſelf as to the parts or paſſes, through which the enemy may or muſt attempt to penetrate, if he expects to penetrate at all. Theſe ſhould be occupied and ſecured by your army, in thoſe places where they are moſt eaſily defended, and where he cannot attack you without great hazard and danger. By acting judiciouſly in this manner you will, with very inconſiderable movements on your part, oblige him to take long and circuitous routes, and thereby haraſs his troops without being able to carry on any ſolid operations.

*An intrenched or retrenched camp.* Such a camp is ſometimes made during a campaign on the field, ſometimes before a place, and ſometimes under a place.

The ancients, and particularly the Romans, did not remain, even for an inconſiderable length of time, in any place without fortifying it. Their intrenchments did not hinder them from marching againſt the enemy when it was thought proper; but they put their armies out of the reach of inſult, particularly when they were compoſed of new levies or of raw and unexperienced troops, furniſhed places of ſecurity for their baggage and proviſions, and enabled them to ſend out large foraging detachments without expoſing their camps to inſult.

It is not ſufficient, when one is on the defenſive, to have your camp on a ſituation naturally ſtrong. It is alſo neceſſary, particularly when the enemy is under the neceſſity of coming to attack you, to remedy and remove the ſmalleſt defects of ground or poſition by intrenchments, which put you completely under cover, and place you in a condition to make a vigorous and obſtinate defence.

In an open or level country, it is adviſable for you, in conſtructing your intrenchments, to avail yourſelf of every advantage that the ground offers, to profit by rivers, rivulets, moraſſes, canals, marſhes, hollow ways, ditches, villages, incloſures, caſtles, &c. and to proportion the relative degrees of ſtrength in your intrenchments, in different places, in ſuch a manner as to render every part of your poſition equally ſtrong.

In a woody and mountainous country, you ſhould not only take all the precautions neceſſary to be obſerved in an open and level one, but ought alſo to make abattis, dikes, batardeaux, &c.

An intrenched or retrenched camp before a place, has for its object both offence and defence, when the enemy is either in ſufficient ſtrength to attempt to raiſe the ſiege, and to throw in ſuccour and relief to the beſieged, to enable them to hold out for a longer time than they otherwiſe would be able, or when the beſieged themſelves are ſufficiently numerous to make ſtrong and frequent ſallies. In the firſt caſe a line of circumvallation is made to ſecure the beſieger's army againſt all attempts from without; and in the ſecond a line of contravallation is thrown up between the beſieger's camp and the place, to prevent any moleſtation or interruption on the part of the beſieged from within.

In conſtructing both theſe lines you ſhould be particularly careful to occupy the moſt commanding and advantageous ground round the place, whether it be a little farther from or nearer to it than you could wiſh, availing yourſelf of heights, ravines, &c., and making uſe of abattis where there is wood, and every thing elſe from which you can derive advantage. If they are interſected by rivers, rivulets, canals, moraſſes, &c. you ſhould have ſecure and convenient bridges and ways of communication between the different parts.

An army of obſervation is even of the greateſt advantage at the commencement of a ſiege. It watches over the beſieger's preſervation till he firmly eſtabliſhes himſelf, can forward his operations, eſcort his convoys, ſupply him with faſcines, and perform many other ſorts of labour for him. Theſe two armies ſhould always be within reach of each other, particularly at the beginning, that they may be able to afford mutual aid and ſuccour to each other, and keep the enemy at a diſtance, who will naturally be afraid of approaching too near, if they are too powerful for him, leſt they ſhould fall upon him conjointly, and attack him with advantage.

Intrenched or retrenched camps under places, which are aſcribed by ſome to the celebrated marſhal Vauban, who recommends the forming of them at moſt frontier places, have defence only for their object. A camp of this ſort may have one particular object only, or ſeveral objects at once. Near or under a place of importance, it ſerves to render the attempt to beſiege it the more difficult, and to retard or hinder the taking of it. Under a place ſurrounded by heights, as well as one that has only a ſimple incloſure or bad fortifications, it becomes neceſſary for its defence. When there is a number of troops in a place, it is uſeful for aſſembling them in, for placing them commodiouſly, and for putting them in a condition to act againſt the enemy, as occaſions may preſent themſelves. It is a ſupport for an army that is not ſtrong enough to take the field, and is convenient for the inhabitants of the neighbourhood to retire to with their effects.

The depth of a regiment of infantry encamped, conſiſting of nine companies of 100 men each, from the ſerjeant's tents to the rear, uſed to be 200 yards, and the front 245, including the battalion-guns. A regiment of infantry of the ſame ſtrength is now allowed 200 yards in front, including its two battalion guns, and 520 yards in depth.

A regiment of dragoons encamped, conſiſting of ſix troops that form three ſquadrons, with the light troops, uſed to take up 200 yards in front and 258 in depth; and the interval between two regiments of infantry or cavalry uſed to be 60 yards.

A ſquadron of horſe has now a front of 120 yards; and an interval of 100 feet is allowed between each regiment.

The forming of an intrenched camp, near a town or village, is attended with many advantages. It furniſhes room for eſtabliſhing magazines for ſtores, forage, baggage, and for the ſick and wounded. The houſes and buildings help to cover its flanks, and thereby enable you to render it more compact than it otherwiſe could be made. Such a camp alſo covers and protects a place that has not works or fortifications ſufficiently ſtrong to reſiſt an enemy. When the ground is favourable for the purpoſe, ſuch a camp may be formed in the figure of a ſquare, or nearly ſo, which will require much leſs extent of intrenchment than a long rectangular one, and is more defenſible.

Some able generals have been for rejecting lines altogether; among which number is the celebrated marſhal Saxe, who is a great advocate, however, for redoubts in front of an army, and mentions particularly the wonderful advantage they were of to Peter the Great and the Muſcovites at the battle of Pultowa. It muſt be allowed that lines and intrenchments are often thrown up on a campaign very injudiciouſly and to little purpoſe; and unleſs ſome parts of them be cloſed in the rear, they are totally loſt the moment they are forced or carried in any one point. But ſuch temporary lines and intrenchments for tranſitory camps are different from thoſe we have juſt been ſpeaking of, either before or under places.

Frederic II., king of Pruſſia, has propoſed to form lines or retrenchments with ſquare redoubts, placed in ſaliant and re-entering angles, with an angle of each outwards or towards the enemy, joining them with trenches, as in *fig.* 4. *Plate* v. *Military*, &c. He obſerves, that the redoubts in the ſaliant angles ought not to be above 600 paces diſtant from one another; but 600 yards are diſtance enough. And the ingenious general Lloyd has propoſed a ſimilar arrangement of redoubts, in front of an army drawn up in order of battle, without joining them with trenches, but leaving the intervals between them open.

*Fig.* 1. *Plate* v. is marſhal Vauban's form of lines, and *figures* 2. and 3. are his firſt and ſecond profiles of them.

*Fig.* 5. is a form for lines, with baſtions and broken curtains.

Camp, *city*, *caſtra urbana*, was a place near the city-wall not far from the *via nomentana*, where the prætorian guard were encamped; whence it was alſo called the *prætorian camp*, *caſtra prætoria*, or *prætoriana*. The like we alſo read of at Jeruſalem, called by St. Luke abſolutely the *camp*, παρεμβολη. By which we are doubtleſs to underſtand the *caſtra antonia*, which Joſephus tells us, was afterwards uſed as a caſtle.

Camps, *mooned*, *caſtra lunata*, thoſe made in figure of a half-moon.

Camp, *naval*, *caſtra nautica*, or *navalia*, denoted a ſtation of ſhips.

Camp, *ſtanding*, *caſtra ſtativa*, was that wherein they deſigned to continue longer in a place; and therefore more pains were taken to fortify and regulate it.

The Roman camps, in a march, were alſo called in the middle age *manſiones*. See Camp, *ſupra*.

Camp, *ſummer*, *caſtra æſtiva*, among the Romans, was ordinarily light and moveable; ſo that they might be ſet up, or taken down, and removed in a night. In which caſe it was alſo called ſimply *caſtra*. See Camp.

Camp, *winter*, *caſtra hyberna*, or winter-quarters, were uſually taken up in ſome city or town; or elſe ſo contrived as to make almoſt a town of themſelves. See Camp.

Camps, *tertiated*, *caſtra tertiata*, thoſe which were a third part longer than broad, which Hyginus repreſents as the Roman model. *Caſtra in quantum fieri potuerit tertiata eſſe debebant—ut puta in longum duo millia quadrigenti, in latum mille ſexcenti pedes.*

Camp is alſo uſed among the Siameſe and Eaſt Indians, for a quarter of a town aſſigned to foreigners, wherein to carry on their commerce.

In theſe camps, each nation forms itſelf a kind of city apart, in which their ſtore-houſes and ſhops are, and the factors and their family reſide.

The Europeans at Siam, and in moſt other cities of the Eaſt, are exempted from this reſtraint, and allowed to live in the cities and ſuburbs, as they find them moſt commodious.

Camp *colours-men*, are ſoldiers appointed to attend and aſſiſt the quarter-maſter general, in marking out, and keeping the camp clean, receiving and diſtributing proviſions, &c.

The camp colours-men are drawn a man out of a company, that are exempt from all other duty during the campaign: each carries either a ſpade or a hatchet, or a pole bearing colours.

Camp *Diſeaſes*, or the diſeaſes incident to armies, are ſuch as ariſe chiefly from expoſure to the heat and inclemency of the weather, and from infection. Conſequently they are different, according to the ſeaſon of the year, and to the climate and ſoil of the country in which the army is engaged. The ancient maxim of Hippocrates, that "the ſummer and autumnal ſeaſons are the moſt ſickly," is confirmed by ſir John Pringle, not only with regard to warm climates, but to every camp, where men are neceſſarily much expoſed to heat and moiſture, the great cauſe of putrid and contagious diſeaſes. (Obſ. on Diſ. of the Army, P. II. ch. i.) The diſeaſes of ſummer and autumn are, remitting and intermitting fevers, cholera, and dyſentery. But the latter, though produced by heat and moiſture, is propagated extenſively by contagion: it declines, however, with the autumn; but the remitting fevers continue as long as the encampment, and never entirely ceaſe till the froſts begin. In the winter, inflammatory diſeaſes chiefly prevail, ſuch as coughs, pleuriſies, acute rheumatiſms, inflammation of the brain, bowels, and other leſs important parts: and the conſequences of theſe are often conſumptions, chronic coughs, and rheumatiſms.

Independently of the noxious effluvia from marſhes, from the privies of the camp, and the putrid ſtraw in the tents, which ſpread diſeaſes through a camp, the ſoldiers are often attacked with the typhous or putrid fever, when crowded together in hoſpitals and barracks in conſequence of the confined air; hence this fever has been demoninated the *hoſpital* fever.

There are other cauſes, alſo, which contribute to the production of diſeaſes in an army, partly by prediſpoſing the body to be more eaſily affected by noxious agents, and partly by actually exciting diſeaſe; ſuch are errors and irregularities in diet, the uſe of bad water, intemperance in ſpirits, the extremes of fatigue and inactivity, loſs of reſt, and want of cleanlineſs. The means of limiting the operation of theſe cauſes were ſuggeſted by Drs. Pringle, Monro, and other authors; and conſiderable improvements in the clothing, and means of ſubſiſtence of the men, in the ventilation of hoſpitals, &c. have been adopted, by which the number and mortality of camp-diſeaſes are ſomewhat diminiſhed.

Camp *duty*, in its utmoſt extent, includes every part of the ſervice performed by the troops during the campaign. But in a more particular ſenſe, it denotes the duty performed by guards and detachments, for the ſecurity of the camps, and preventing ſurpriſes.

Part of the camp duty is performed in the ſame manner as that of a garriſon.

Camp *fight*, or Kamp *fight*, in *Law Writers*, denotes the trial of a cauſe by duel, or a legal combat of two champions in the field, for the deciſion of ſome controverſy.

In the trial by camp fight, the accuſer was, with the peril of his own body, to prove the accuſed guilty; and by offering him his glove, to challenge him to this trial, which the other muſt either accept of, or acknowledge himſelf guilty of the crime whereof he was accuſed.

If it were a crime deſerving death, the camp fight was for life and death: if the offence deſerved only impriſonment, the camp-fight was accompliſhed when one combatant had ſubdued the other, ſo as either to make him yield, or take him priſoner. The accuſed had liberty to chuſe another to fight in his ſtead, but the accuſer was obliged to perform it in his own perſon, and with equality of weapons.

No women were permitted to be ſpectators, nor men under the age of thirteen. The prieſt and the people, who looked on, were engaged ſilently in prayer, that the victory might fall on him that was right. None might cry, ſhriek, or give the leaſt ſign; which, in ſome places, was executed with ſo much ſtrictneſs, that the executioner ſtood ready with an axe to cut off the right hand or foot of the party that ſhould offend herein.

He that, being wounded, yielded himſelf, was at the other's mercy, either to be killed or ſuffered to live. But if life were granted him, he was declared infamous by the judge, and diſabled from ever bearing arms, or riding on horſeback. Verſteg. Reſt. Dec. Intell. cap. iii. p. 51. See Acre-*fight*, Battle, Champion, and Combat.

Camp *hoſpital*. See Hospital.

Camp *law*, a method of deciding controverſies by duel or camp-fight.

Camp-*mills*, in the *Military Art*, denote portable or moveable mills, which can be uſed, particularly in time of war, when there are neither wind-mills nor water-mills in the neighbourhood, and which, on that account, formerly accompanied armies, in the ſame manner as camp-ovens and camp-forges. Some of theſe mills have ſtones for grinding the corn, and others are conſtructed with a notched roller like thoſe of our coffee-mills. Some of them are alſo ſo contrived, that the machinery is put in motion by the revolution of the wheels of the carriage, in which they are placed; and others, more commonly, are driven by horſes or men, after the wheels of the carriages are ſunk in the ground, or faſtened in ſome other manner. The invention is aſcribed to Pompeo Targone, engineer to the marquis Spinola, about the end of the 16th century. Others aſcribe the invention to the Germans, about the year 1633. Beckmann's Hiſt. Invent. vol. iii. p. 160.

Camp of *Gold Cloth*, in *Hiſtory*, a denomination given to the ſcene of interview between the kings of France and England, Francis and Henry, and their reſpective queens, in 1519; ſeated between Ardres and Guines. This interview was conducted with ſingular magnificence and ſplendour; it laſted 10 or 12 days, exhauſted the treaſures of both monarchs, ruined many of their nobility, and terminated without anſwering any uſeful purpoſe.

CAMPACH, in *Geography*, a river of Carinthia, which runs into the Moll, near Velach.

CAMPÆ, in *Ancient Geography*, a town of Cappadocia, in the department of Cilicia. Ptolemy.

CAMPAGNA, in *Geography*, a town of Naples, in Principato Citra; the ſee of a biſhop, ſuffragan of Conza; 16 miles E. N. E. from Salerno, and 13 S.S.W. from Conza.

Campagna *di Roma*, formerly *Campania*, a province of Italy, in the ſtate of the church, comprehending the greater part of ancient Latium, and bounded on the north by the river Sabina, on the eaſt and ſouth-eaſt by Abruzzo Ultra and Lavoro, on the ſouth-weſt by the Mediterranean, and on the north-weſt by the Patrimony of St. Peter. It is about 60 miles long on the Mediterranean ſea, and 33 broad. The country contains many beautiful plains, and the ſoil is fertile; but a great part of it is inſalubrious on account of the Pontine marſhes, ſo that there are few towns or villages, and the inhabitants are poor. Several attempts have been made to drain theſe marſhes, and they are now traverſed by a firm road. By theſe means, and ſome internal regulations in favour of the huſbandmen, the inſalubrity of the air is likely to be corrected, and the population and fertility of the province increaſed. The unwholeſomeneſs of the climate in this province is ſaid to have commenced after the invaſion of the Goths in the 5th and 6th centuries; and to have been owing to the accumulated ruins of the edifices of Rome, which raiſed the bed of the Tiber, and cauſed its waters to ſtagnate and to overflow. The exhalations proceeding from ſuch a maſs of ſtagnated waters, contributed very much to infect the air of this hot climate. This evil, reſulting from the ſame cauſe, was aggravated as long as Rome was expoſed to the incurſions and devaſtations of the Lombards, the Normans, and the Saracens, which laſted for ſeveral centuries. At the beginning of the 13th century, the air was become ſo infectious, that Pope Innocent III. ſays, that few people at Rome attained to the age of 40 years, and that it was very uncommon to ſee a perſon of 60. When the papal ſee was transferred to Avignon, and during the 72 years of its continuance there, Rome became a deſert. Its monaſteries were converted into ſtables; and Gregory XI. on his return to Rome in 1376, could ſcarcely count in it 30,000 inhabitants. His death was ſucceeded by the weſtern ſchiſm, which continued upwards of 50 years; and when this ſchiſm terminated in 1492, Martin V. and thoſe who immediately ſucceeded him, were able to make but feeble efforts againſt ſo inveterate an evil. It was not till the commencement of the 16th century, that Leo X. vigorouſly attempted to reſtore the ſalubrity of the air; but the two ſieges of Charles V. plunged it again into its old calamities; and the number of inhabitants, which in the time of Leo X. amounted to 85,000, was reduced under Clement VIII. to 32,000. Since the time of Pius V. and Sixtus V. towards the cloſe of the 16th century, the popes have been aſſiduous in their endeavours to purify the air of Rome and its environs, by procuring proper diſcharges for the waters, drying up the moiſt and marſhy grounds, and covering the banks of the Tiber and other places that were deemed uninhabitable with ſuperb edifices. Since that time a perſon may dwell at Rome, and go in or out of it, at all ſeaſons of the year. But at the beginning of the laſt century, they never ventured to ſleep at Rome, even in the day, in any other houſe beſide their own. But theſe ſcruples, ſays M. Condamine, have of late very much ſubſided; and he ſays, that he has ſeen cardinals, in the months of July and Auguſt, go from Rome to lie at Fraſcati, Tivoli, Albano, &c. and then return the next or the following days to the city without any detriment to their health; and he adds, that he has himſelf tried all theſe experiments, without the leaſt inconvenience. "We have even ſeen," he ſays, "in the laſt war in Italy, two armies encamped under the walls of Rome, at the time when the heats were the moſt violent. Nevertheleſs, the country people in general dare not ſtill venture to lie, during that ſeaſon of the year, nor even ſo much as ſleep in a carriage, in any part of the territory comprehended under the name of the Campagna of Rome." The amphitheatre of hills that bound the Campagna on one ſide is crowned with towns, villages, and villas, which form very delightful landſcapes. The ancient Romans were accuſtomed to ſeek ſhelter from the ſcorching heats of ſummer among the woods and lakes of thoſe hills; and the cardinals and Roman princes, at the ſame ſeaſon, retire to their villas; while many of the wealthier citizens take lodgings in the villages, during the ſeaſon of vintage. The principal cities or towns of Campagna, are Rome, Velletri, Fraſcati, Paleſtrina, Terracina, Nettuno, and Oſtia. N. lat. 41° 18′ to 42°. E. long. 12° 14′ to 13° 29′.

CAMPAGNAC, a town of France, in the department of Aveyron, and chief place of a canton in the diſtrict of Milhau; the place contains 1531 inhabitants, and the canton 6107. The territory comprehends 140 kiliometres, and 7 communes.

CAMPAGNE, a town of France, in the department of the Straits of Calais, and chief place of a canton in the diſtrict of Montreuil; 2 leagues weſt of Heſdin. The place contains 1209, and the canton 11,508 inhabitants: the territory includes 212½ kiliometres and 25 communes.

CAMPAGNOL VOLANT, (Daubent,) in *Zoology*, Schreber's VESPERTILIO HISPIDUS, and great bearded bat of Senegal. Penn. Syn.

CAMPAGNOL, of Buffon, is the ſhort tailed rat of Engliſh writers, Mus campaignols of Geſner, and mus arvalis of Pallas, Schreiber, &c.

CAMPAIGN ſignifies a field, an open or level country.

In a military point of view, it is uſed to denote the ſpace of time, every or each year, during which troops are kept embodied as an army, or at leaſt in a condition to ſtop, thwart, or traverſe the progreſs of the enemy.

This term is alſo employed to expreſs the number of years which an officer or ſoldier has ſerved. This officer has ten campaigns over his head, that is to ſay, he has been ten years in the ſervice: this ſoldier has made ſixteen campaigns, that is, he has ſerved ſixteen years.

It is likewiſe made uſe of to ſignify the operations of a campaign. Thus we ſay, he wrote the hiſtory of that campaign; by which we mean to ſay, that he wrote the hiſtory of the tranſactions and operations that took place during that campaign. A general is ſaid to begin or open the campaign when he commences his operations.

The genuine object of a campaign is to attack your enemy, or to defend yourſelves, or to ſuccour an ally; and whichever of theſe be the object, it is neceſſary to have armies more or leſs numerous, money to pay them with, and to defray the other expences attending it, and conſiderable magazines of every ſort near the frontiers, where the armies are to aſſemble and operate. The general plan of a campaign is the reſult of political deliberation and arrangement, and is regulated by circumſtances and conjunctures.

Though campaigns may have different objects, as well as be opened and carried on at different times and ſeaſons, they may all be conſidered as falling under the following diſtinctions or denominations:

Offenſive campaigns.
Defenſive campaigns.
Summer campaigns, and
Winter campaigns.

In an *offenſive war*, you ought to conſider whether it is beſt to act offenſively every where, or to act on the defenſive in one quarter, to enable you to act with more vigour and effect in another. It is moſt adviſable to attack a country of which the conqueſt has a tendency to lead to a ſpeedy peace, or at leaſt to prove favourable to the opening of the next campaign. But it is of importance, before you undertake any ſuch enterpriſe, to know to a certainty that the powers, whoſe jealouſy you might excite, will not oppoſe the conqueſt you intend to make.

In a *defenſive war*, you ought to conſider what frontiers it is of moſt conſequence to defend. When you are inferior to the enemy, and find it difficult to defend your country with ſmall armies, you ſhould take care not to divide your force, but to keep your troops together in thoſe quarters where you have moſt to fear, in order to engage him with all your force, ſhould you be under the neceſſity of fighting him. Such conſiderations may ſometimes determine you to abandon one tract of country, and lay it waſte, in order to preſerve and protect another of greater importance.

When your object is to ſuccour or aſſiſt an ally, either in virtue of a treaty concluded with him, or to prevent his being ſubdued by ſome formidable power that wiſhes to invade his country, and ſtrip him of his territories, you ſhould, in the firſt inſtance, have ſome ſtrong and ſecure places of his put into your hands to prevent his making a peace without your participation and concurrence, and to keep open a ſafe retreat for you, ſhould you be forced to retire.

In every ſituation and ſpecies of warfare, either in commencing or continuing it, you ought not to enter on a campaign but after much and mature deliberation. You ſhould weigh every circumſtance, conſider what may happen, and ſuppoſe even the worſt, that you may not be ſurpriſed by incidents or events, but benefit by ſuch as are favourable, and ſpeedily remedy thoſe that are otherwiſe.

You ſhould not inveſt more than one perſon with the chief command of an army. For perſons who enjoy equal authority are generally of different ſentiments and opinions; and although no inconvenience aroſe to the allies from the coequal and joint command of prince Eugene and John duke of Marlborough, which was owing principally to the prudence and great good ſenſe of the latter, and to a magnanimity of mind natural to both, yet it ought not to be quoted as an example for imitation.

You ſhould keep your preparations as ſecret as poſſible, and endeavour to open the campaign with ſome blow or enterpriſe of importance, not ſuſpected by the enemy; and when you act in concert with allies, you ought to arrange and ſettle with them a general plan, that your ſucceſs may be thereby rendered more certain and rapid, and that the operations of the different armies may be ſo regulated and conducted, particularly in reſpect of time, which governs in the affairs of war, as to be conducive to the bringing about of the ſame object or end.

When a general is appointed to act, either offenſively or defenſively, it is neceſſary for him to have an exact knowledge of the ſituation, condition, and nature of the frontier and country where he is to act, to be able to ſettle properly a particular plan for the campaign. His conduct or management of a *campaign* is his manner of executing the plan of operations offenſive or defenſive, that he has formed.

The general maxims for a campaign of *offenſive* operations are chiefly the following:

To undertake no enterpriſe without mature deliberation.

To obſerve profound ſecrecy; as the beſt plans and deſigns are thoſe which the enemy is not only ignorant of, but does not even ſuſpect.

After an enterpriſe is once reſolved on, to carry it as ſpeedily into execution as poſſible.

To undertake no enterpriſe raſhly, but to conſider well the poſſible ways and means of executing it, and to be prepared to overcome with prudence and reſolution the probable obſtacles you may meet with in the execution.

Before you undertake any thing, to form magazines in different ſituations near your army, and to procure the means of tranſporting them with facility from one place to another.

When you penetrate into an enemy's country, to advance gradually rather than leave ſtrong fortreſſes behind you, and not to move unneceſſarily to a diſtance from navigable rivers convenient for the tranſport of ammunition and proviſions.

Not to enter on any enterpriſe without ſecuring a communication with your depots, and eſtabliſhing a protection for your convoys.

On entering an enemy's country to make the natives and people believe that your force is much greater than it really is, by undertaking as many enterpriſes at once as you can with ſucceſs and ſafety.

To eſtabliſh and ſtrengthen yourſelf in ſome advantageous poſition as a central poſt, from which you can ſupport all your ſubſequent movements.

To ſtudy the courage, talents, and diſpoſition of your officers and ſoldiers, to know which of them are fitteſt for one ſort of ſervice or enterpriſe, and which for another.

To take care to give your orders in writing, always when you can, as clearly and conciſely as poſſible.

To render the condition and ſituation of the troops as pleaſant and comfortable as you are able, whilſt you make them obſerve a rigid and exact diſcipline, and inure them to exerciſe and labour.

To conciliate the eſteem and affection of your troops.

To chooſe ſuch advantageous poſitions as will enable you to ſupport and command all operations to a conſiderable extent on every ſide of them, as will force the enemy to quit his and put it in your power by ſhort, ſimple, and eaſy movements on your part to compel him to make long, tireſome, and circuitous marches.

Not to revile or reproach your troops when they happen to be beaten, but to animate them and renovate their ſpirits.

To endeavour by every method to procure exact information in regard to the enemy's force and deſigns; and, above all things, to become acquainted with the real characters, diſpoſitions, ruling paſſions, and propenſities of the generals oppoſed to you.

Theſe maxims ought alſo to be obſerved by a general who is entruſted with the conduct or management of a defenſive campaign. There are a few others, however, peculiar to it, which it may not be improper to take notice of.

He ſhould endeavour to diſcover on what part of the frontier the enemy intends to aſſemble his troops, and of the object he has in view, by the ſituations, number, and nature of his depots; to put himſelf in a condition to oppoſe and fruſtrate his deſigns by proviſioning and furniſhing with ſufficient ſupplies the places that are moſt important and moſt expoſed, by reconnoitring good and ſtrong poſitions, and by taking every poſſible meaſure to prevent anticipation on the part of his opponent.

A general acting defenſively ſhould avoid an engagement where ſuperiority in numbers is of much avail; and, on the other hand, he ought to embrace any favourable opportunity of fighting the enemy in a ſituation where diſpoſition is every thing, and number nothing.

He ought himſelf to be active, vigilant, bold, enterpriſing, and capable of enduring fatigue.

He ſhould endeavour, by every ſtratagem, to draw the enemy into diſadvantageous and dangerous ſituations, where he can attack him with advantage, and without much riſk of loſing many men.

He ought not to occupy any poſition which the enemy can ſurround or ſhut him up in.

He ſhould, where it is neceſſary, ſecure his camp with intrenchments, placing his flanks out of the reach of inſult.

A general who has made ſome conqueſts, comes to be on the defenſive when he is ſtopped in his career of victory. He ſhould, therefore, ſeriouſly conſider whether he is able to keep or preſerve them, and what meaſures he ought to adopt for that purpoſe. For it is ſometimes eaſier to make conqueſts than to retain them after they are made.

When a general is on the defenſive, it is a material conſideration for him to be able to foreſee in good time and determine where he ſhall retire to, in order to take up his winter quarters, and to poſſeſs himſelf of every thing that can contribute to enſure their tranquillity. If, at the cloſe of a campaign he finds he has but little or no country left him to defend, no allies, with whom he can take refuge, or from whom he can receive ſuccour or ſupport, and that his means of repulſing the enemy are exhauſted, it is beſt for him to demand an armiſtice, and to open negociations for peace.

The cloſe, end, or concluſion of a *campaign* is the time when the oppoſing armies go into winter quarters. Sometimes one of them remains in the field longer than the other, but they generally both retire from it at the ſame time.

*Summer campaigns*. Almoſt all campaigns are made in ſummer, and none in winter, except in caſes of neceſſity, or when great and important advantages are expected to be derived from them.

Campaigns are generally opened in the ſpring; but ſome nations are later in opening them than others. In this reſpect ſome are neceſſarily regulated by climate, while others are governed by cuſtom.

It has been cuſtomary for moſt of the nations of Europe to open their campaigns in the month of March. The Turks are always later than them in taking the field, and quit it ſooner. This is owing to the great extent of country from which they have to collect their militia, their great number of cavalry, for which they muſt have paſture, and the immenſe quantites of baggage they carry along with them.

Moſt generals have endeavoured to take the field as ſoon as they were in readineſs for entering on the campaign, or as circumſtances would permit. But the celebrated and very ſucceſsful marſhal Saxe was an advocate for taking the field late in the ſeaſon. On this ſubject he expreſſes himſelf in theſe words:

"Many perſons are of opinion that it is advantageous to take the field early; in which they judge very properly, provided there is any important poſt to be ſeized or enterpriſe to be executed that requires it; but otherwiſe I am far from concurring with them, and think there is no occaſion for ſuch precipitate meaſures, but, on the contrary, that it is even prudent to remain in winter quarters much longer than the uſual time. The enemy's being ſuffered to lay ſiege to a place is of no ſignification, becauſe he will thereby only weaken and diſpirit his troops; and if you fall upon him towards the autumn with an army well diſciplined and in good order, he muſt infallibly be ruined. I have always remarked that a ſingle campaign reduces an army one-third at leaſt, and ſometimes one-half, and that the cavalry, in particular, is in ſo wretched a condition by the beginning of October, as to be no longer able to keep the field."

*Winter campaigns,* are campaigns carried on in winter.

There are ſome countries in which the climate is ſo ſevere, and the froſt ſo intenſe, that it is impracticable to make campaigns in them in winter. But in others, where they are practicable, in conſequence of the mildneſs of the climate, there are circumſtances that ſometimes render them neceſſary, and point out ſuch great advantages to be derived from them, though very diſtreſſing and injurious to troops, that a general does not much heſitate about undertaking them.

If an enemy has taken up his winter-quarters in one of your provinces or diſtricts of country, with the intention of invading a neighbouring or adjoining province early in the ſpring; and you underſtand that his cantonments are much ſcattered or extended, and think you can approach them without his being appriſed of your deſign in ſufficient time to collect his force, beat them up in ſucceſſion or detail, and diſperſe his army, obliging him to retire and abandon that tract of country, you ought to open a winter-campaign for the accompliſhment of ſuch an object.

There are but few circumſtances or conſiderations, however, that will juſtify the opening of a winter-campaign, which ought not on any account almoſt to be made in a country where there are many ſtrong places, which cannot be reduced but by long and tedious ſieges.

Frederic II. king of Pruſſia, who made more winter-campaigns than any other general of the laſt century, in ſpeaking of them expreſſes himſelf in the following words:

"Winter-campaigns are the ruin of your troops, not only on account of the ſickneſs they occaſion, but becauſe from your continual motion they can neither be clothed nor recruited. The ſame want of repoſe prevents all your carriages, &c. from being properly repaired, and ends in their total deſtruction.

"Nothing can be more certain than that the beſt army in the world cannot long ſupport ſuch campaigns; for which reaſon winter expeditions ought by all means to be avoided; not but that there is a poſſibility of a general being ſo circumſtanced as to be obliged to have recourſe to that kind of ruinous war."

CAMPAN, in *Geography*, a town of France, in the department of the Higher Pyrenées, and chief place of a canton, in the diſtrict of Bagnères, ſeated in a valley, which derives from it its name; 1 league S. of Bagnères-en-Bigorre. The place contains 4,200, and the canton 7,224 inhabitants; the territory includes 250 kiliometres, and 7 communes.

CAMPANA, a town of Naples, in the province of Abruzzo Ultra; 8 miles S.S.E. of Aquila.—Alſo, a town of Naples, in the province of Calabria Citra; 9 miles S. W. of Cariati.—Alſo, a ſmall iſland in the South Pacific Ocean, near the weſt coaſt of South America. S. lat. 48° 50′. W. long. 77° 51′.—Alſo, a river of South America, which runs into the Pacific Ocean. S lat. 48° 50′. W. long. 77° 41′.

CAMPANA, *La*, a town of Spain, in the country of Seville; 13 miles W. of Ecija.

CAMPANA *Floræ*, in *Botany*, a name given by Helwing, and ſome other of the German authors, to the plant we call *pulſatella*, or the *paſque flower*. It was named *campana Floræ*, or Flora's bell, by Helwing, becauſe of its being the ſignal of the approach of ſpring. In the Linnæan ſyſtem, this is a ſpecies of the ANEMONE.

CAMPANACEI, the thirty-ſecond natural order in the Philoſophia Botanica of Linnæus, and the twenty-ninth of the Poſthumous Lectures publiſhed by Giſeke. It contains the following genera: *Evolvulus*, Convolvulus, Ipomea, *Retzia*, *Falckia*, Polemonium, Campanula, *Canarina*, Roëlla, Phyteuma, Trachelium, Jaſione, Lobelia, Viola, *Parnaſſia*. Thoſe printed in Italics are not mentioned in the Philoſophia Botanica. None of them are arboreous; few ſhrubby; in all, the leaves are alternate, the calyx five-cleft, the corolla five-cleft, the ſtamens five, the ſtyle one (except in evolvulus, in which it is not certain whether it has four ſtyles, or one ſtyle with four ſtigmas,) and the pericarp a capſule. They are all lacteſcent, at leaſt when young and tender, and have a purgative ſlightly poiſonous quality; they have all a common character, but it is not poſſible to give them an excluſive one by which they may be diſtinguiſhed from all others.

CAMPANARIO, in *Geography*, a town of Spain, in New Caſtile; 10 miles from Paluccio-del-Rey.

CAMPANELLA, THOMAS, in *Biography*, a philoſopher of Italy, prompted by his genius to bold innovations, and remarkable for the ſufferings occaſioned by them, was born at Stilo, a village of Calabria, in 1568, and diſtinguiſhed himſelf, at a very early period, by his talents and application. At the age of 14 years he wrote verſes with great facility; and in his 15th year he entered into the order of the Dominicans. Having acquainted himſelf betimes with the ſcholaſtic theology of the age in which he lived, he directed his attention with great ardour to the ſtudy of philoſophy; and diſſatisfied with the opinions of Ariſtotle and other ancient philoſophers, becauſe, as he ſays, he did not find them conformable to the great volume of nature, he imbibed the bold and free ſpirit of inquiry manifeſted by Teleſius, in a work "On the Nature of Things," which then engaged much attention in Italy. Accordingly he publiſhed, at Naples, in 1591, a defence of this work in direct oppoſition to the philoſopoy of Ariſtotle, under the title of "Philoſophia Senſibus demonſtrata," or, Philoſophy demonſtrated to the Senſes. His determined oppoſition to long eſtabliſhed tenets, and his contempt of the authority of Ariſtotle, excited prejudices againſt him among his monaſtic brethren. Nevertheleſs, as he had ſome powerful patrons, he perſevered in his deſign of attempting the reformation of philoſophy: and he wrote two treatiſes, one "De Senſu Rerum," on ſenſation; the other, "De Inveſtigatione," on inveſtigation; thus propoſing to direct young perſons in the acquiſition of the knowledge of things, by a more eaſy and effectual method than that which had been taught by Ariſtotle or Plato. However, he was at length under a neceſſity of ſaving himſelf from inſult and perſecution by removing from Naples to Rome, and afterwards to Florence, Venice, Padua, and Bologna. At this latter place all his papers were clandeſtinely taken away and ſent to the inquiſition at Rome. At laſt he ſettled in his native country, and with a view of diſguiſing his innovations, wrote in defence of the See of Rome. In 1599 he was ſuſpected of entertaining hoſtile deſigns againſt the Spaniſh government, and of making himſelf maſter of the Higher Calabria; and committed to priſon at Naples, under a charge of high treaſon. He was ſeven times ſubjected to the torture, and during his confinement he was, for a conſiderable time, debarred the privilege of reading and writing, and of all intercourſe with his friends. Among other accuſations alleged againſt him, he was charged with having written a book, entitled "De Tribus Impoſtoribus," which, as he himſelf ſays, had been printed 30 years before he was born; when the rigour of his confinement was ſo far abated, that he was allowed to write and to correſpond with his learned friends, he compoſed ſeveral books, which were publiſhed in Germany. Many attempts were made for his liberation; and, at length, in 1626, pope Urban VIII. prevailed upon Philip IV. of Spain, to acquit him from the charge of treaſon, and he was removed to the priſon of the inquiſition at Rome, where he was confined under a pretext of hereſy till the year 1629, when he was finally liberated, after an impriſonment of about 30 years. The pope, who was a patron of learned men, in conſideration of his ſufferings, granted him a penſion, together with the title of his domeſtic. But here he was ſtill purſued by the reſentment of the Spaniards, and, therefore, the pope warned him of his danger, and aſſiſted him to make his eſcape to France, where he experienced the favour of cardinal Richelieu, who procured for him a penſion from Louis XIII. At Paris he lodged in the Dominican convent of St. Honore, and was much reſpected by men of learning, who ſought his converſation. This happy change in his ſituation was of no long continuance, for he died in 1639, as ſome have ſaid, from the imprudent uſe of antimony.

Campanella was much more diſtinguiſhed by the fertility of his imagination than by the ſoundneſs of his judgment. In this latter reſpect he was notoriouſly deficient, as many of his reveries ſufficiently evince. Beſide the credit which he gave to the art of aſtrology, and to a variety of ſupernatural cures, ſome of which reſemble thoſe of the Meſmerians or Magnetiſers of a later period, he fancied that demons appeared to him, and in a ſtate between ſleeping and waking, warned him of any threatening dangers. But, notwithſtanding the eccentricity of his genius, and his childiſh credulity, he had his lucid and happy intervals, in which he reaſoned more ſoberly. The extent of his erudition appears from his numerous writings, and particularly from his treatiſe "De Recta Ratione Studendi," or, on the right method of ſtudying; in which he pronounces judgment on a number of authors in philoſophy, poetry, oratory, hiſtory, theology, medicine, and mathematics, and lays down excellent rules for the proſecution of philoſophical ſtudies, and the knowledge of nature, which he propoſes to deduce from obſervation and experience. Many of his own opinions, however, on dialectics, phyſics, and ethics, were unintelligibly abſtruſe, and expreſſed with great obſcurity. Whilſt it ſeems to have been his aim to recede as far as poſſible from the ſyſtem of the Peripatetics, his own logic abounds with ſubtle diſtinctions, uſeleſs terms, and obſcure rules, which are not eaſily comprehended. Concerning nature, his leading doctrines were, that ſenſe is the only guide in philoſophy; that ſpace is the firſt incorporeal ſubſtance, immoveable, and the receptacle of all bodies; that time is the ſucceſſive duration of things, and only meaſured by motion; that heat and cold are the two principles, which act on the maſs of matter, the heavens having been produced by the former from rarefied matter, and the earth by the latter, from matter condenſed; that the ſun and earth are the two elements, whence all things are produced; that all animal operations are produced by one univerſal ſpirit; that all things in nature are endowed with feeling and perception; that the world is an animal or ſentient being, inſpired by a ſoul, by which it is directed, as man is by the divine principle within him; that the firſt, greateſt, and only true being, in whom power, wiſdom, and love exiſt as primary principles, tranſmits his inexhauſtible ideas by means of the active cauſes, heat and cold, to the corporeal maſſes, ſupported in ſpace, the baſis of the world, which itſelf has its ſtability in God; that all creatures are excellent in proportion to the degree in which they bear the image of eſſential principles of the divine nature; and that human depravity conſiſts in the loſs of this image, and human perfection in its reſtoration. His works contain a variety of other articles, which are very fanciful and obſcure. It redounds, however, in no ſmall degree to the praiſe of Campanella, that he expoſed the futility of the Ariſtotelian philoſophy, and that he wrote an apology for Galileo, with a defence of his ſyſtem. His acuteneſs in the ſcience of politics is diſplayed in his "Political Aphoriſms," and in his book "De Monarchia Hiſpanica;" but his principles reſemble thoſe of Machiavel. Whilſt he profeſſed to be a reformer in philoſophy, he was deſtitute of that ſober and ſound judgment, which was neceſſary for producing any very important and permanent effect. He was accuſed of impiety; but he ſeems to have been rather a fanatic and enthuſiaſt than an atheiſt. He was alſo accuſed of ſuggeſting cruel meaſures againſt the proteſtants, and, as Moſheim ſays, not without reaſon. Brucker's Hiſt. of Philoſ. by Enfield, vol. ii. p. 529. Moſh. Hiſt. vol. iv. p. 164.

Campanella, in *Geography*, a cape on the coaſt of Italy, nearly ſouth from the city of Naples, acroſs the gulf, of which it is the moſt ſoutherly point. The iſland of Cabrita lies to the weſt of it. See Cabrita.

CAMPANIA, now Campagna, in *Ancient Geography*, the moſt pleaſant and fertile province of Magna Græcia, deſcribed by the ancients under the appellation of "Regio Felix." It extended from the N.W. to the S. E. along the Mediterranean; and was bounded on the N.W. by Latium, on the S.E. by Lucania; and ſeparated from Samnium by a chain of mountains. Its principal mountains were Meſſicus, Gaurus, and Veſuvius; its lakes were the Avernus and Lucrinus; its rivers the Savus, Vulturnus, Clanis, and Silarus, which ſeparated it from Lucania. Capua was conſidered as its capital; beſides which it had ſeveral other conſiderable towns. See Campagna.

CAMPANIAN *diſeaſe*, *Morbus campanus*, in *Antiquity*, is variouſly explained by modern writers. Some will have it only a ſort of tubercles, or warts, on the face, to which the people of Campania were liable. Others maintain it to be the venereal diſeaſe; and hence draw an argument againſt the ſuppoſed novelty of that malady. Dacier will have it to be ſomething ſtill worſe; the Campanians, it ſeems, were addicted to a ſort of commerce too abominable to be named, *ore morigeri erant*. Whence it is, Plautus repreſents them as more pathic or paſſive than the Syrians themſelves. Hor. Stat. v. lib. 1. ver. 62. cum not. Dacier.

CAMPANIFORM, or Campanulated, in *Botany*, a denomination given to flowers in their form reſembling a bell.

CAMPANILE, in *Architecture*. This word, derived from *Campana*, Ital. a bell, is particularly uſed to denominate the bell towers which it is cuſtomary in Italy to erect, not like our ſteeples upon the churches, but detached from them.

Theſe edifices ornament moſt of the Italian towns, and are many of them remarkable for loftineſs and magnificent decoration. Of theſe, the campanile of Cremona is the moſt celebrated: this ſtructure is 395 feet in height, including the croſs; a ſquare tower riſes 262 feet, which is ſurmounted by two octagon ſtories, open to the air, and ornamented with columns; a conical ſhaft and a croſs terminate the elevation. The campanile of Florence is a tower of 267 feet high, on a baſe of 45 feet ſquare, entirely encruſted with marble of various colours. It was built from the deſigns of Giotto, and in ſpite of the veſtiges of a barbarous taſte which it exhibits, muſt be admired for its richneſs and workmanſhip.

Great elevation combined with narrowneſs of baſe has occaſioned, in ſeveral of theſe buildings, conſiderable ſettlements, and remarkable deviations from the perpendicular. This effect is ſenſible in the campaniles of Ravenna, Padua, and St. Agnus at Mantua, but particularly in thoſe of Bologna and Piſa. The campanile of Bologna, which is called the tower of Gariſendi, built in 1110, is 153 feet in height, and varies eight feet and a half from the perpendicular. It has been often aſſerted, that the tower was purpoſely ſo conſtructed, by the caprice of the architect; however, the interior of the building, the tables of the windows, and even the ſcaffolding holes, have all the ſame inclination, which ſeems ſufficiently to prove it to be owing to the ſinking of the ground. The durability of this tower is owing to its conſtruction with bricks, and an excellent cement, which ſeems to unite the whole into one maſs. The neighbouring tower, called *Degli Aſinelli*, has an elevation of 320 feet, and an inclination of three feet and a half, but the overhanging of the firſt is ſo remarkable, that this is not perceived.

The campanile of Piſa, called *Torre Pendente*, is, however, the moſt extraordinary of theſe. Its form, which is neither of a bad proportion, nor ill decorated, is a cylinder ſurrounded with eight ſtories of columns placed over one another, having each its entablature: the laſt ſtory, which forms the belfrey, retires from the general line of elevation. All the columns are of marble, and ſeem to have been taken from the ruins of ancient edifices; each column carries the ſpringing of two arches, and there is an open gallery between the columns and the circular wall of the tower.

The height to the platform is 150 feet, and a plumb line lowered thence to the ground falls nearly 13 feet beyond the baſe of the building.

CAMPANO, Gianantonio, or John Anthony, in *Biography*, an eminent Italian philologiſt, was born in Campania, in 1429; and from the obſcure condition of a ſhepherd, became a diſtinguiſhed ſcholar and writer. At Naples he enjoyed the benefit of Lorenzo Valla's inſtruction; and at Perugia, having in his 23d year applied to the ſtudy of the Greek language, he was advanced to the office of profeſſor of eloquence, which he occupied with great applauſe. In 1459, he attached himſelf to the Roman court, and ingratiated himſelf with pope Pius II. to ſuch a degree, that he was created by him, firſt, biſhop of Crotona, and then of Teramo. At Rome he aſſiſted Udalric, called Gallus, the firſt printer who ſettled there, in preparing MSS. for the preſs, and correcting them when printed, and writing prefaces for ſeveral of his editions. In 1471, he was deputed by Paul II. to the congreſs of Ratiſbon, held for the purpoſe of framing a league among the Chriſtian princes againſt the Turks; on which occaſion he employed himſelf in collecting ancient MSS., which he ſent into Italy. Campano was raiſed ſucceſſively by Sixtus IV. to the governments of Todi, Foligno, and Citta di Caſtello. But as he remonſtrated with the pope on the calamities which the inhabitants of the latter place ſuffered, when it was beſieged by his troops, he was deprived of his government; and withdrawing from the eccleſiaſtical ſtate, he repaired to the court of Naples. But being diſappointed of the preferment which he expected, he retired to Teramo, where he cloſed his life, in 1477. His various works, conſiſting of political and moral treatiſes, orations, letters, eight books of Latin poems, and the Hiſtory of Andrew Braccio, were publiſhed by Michael Ferno; and a new collection of them was edited at Leipſic by Mencken in 1707 and 1734. Gen. Dict. Tiraboſchi.

Campano, *Novareſe*, a diſtinguiſhed Italian geometer and aſtronomer, flouriſhed in the time of Urban IV., to whom he was chaplain, in the 13th century. He wrote Commentaries on Euclid, and he is ſaid to have tranſlated Euclid into Latin from the Arabic verſion; but Tiraboſchi aſcribes this tranſlation to Adelard, an Engliſh monk. He alſo wrote a treatiſe on the quadrature of the circle.

Several aſtronomical works of his compoſition, which treat of the motions of divers planets, or the inſtruments neceſſary for obſerving them, on the eccleſiaſtical computation, and on the theory of the planets in general, exiſt in MS. in various libraries. Tiraboſchi.

CAMPANOLOGIA, from *campana*, *bell*, and λογος, *ſcience*, the art or ſcience of ringing of bells.

CAMPANULA, in *Botany*, (Lat. a little bell.) Linn. gen. 218. Tourn. Tab. 37. Schreb. 290. Gært. 586. Tab. 31. Willd. 329. La Marck. Illuſt. 345. Tab. 123. Juſſ. p. 164. Vent. vol. ii. p. 470. Claſs and order, *pentandria monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Campanulaceæ*, Juſſ.

Gen. Ch. *Cal.* perianth ſuperior, five-cleft, Linn. Gært. Lam. (in ſome ſpecies ten-cleft; five of the ſegments reflexed, and covering the capſule, Juſſ.) *Cor.* monopetalous, bell-ſhaped, five-cleft, ſhrivelling; ſegments broad, acute, ſpreading. *Nectary* in the bottom of the corolla; compoſed of five, acute, connivent valves, covering the receptacle. *Stam.* five, capillary, very ſhort, inſerted on the tips of the valves of the nectary; anthers longer than the filaments, erect. *Piſt.* germ inferior, angular; ſtyle thread-ſhaped, generally longer than the ſtamens; ſtigma two, three, or five-cleft, oblong, thickiſh; ſegments revolute. *Peric.* capſule inferior, angular; either top, egg, or priſm-ſhaped; two, three, or five-celled; in moſt ſpecies emitting the ſeeds at as many lateral holes as there are cells; in a few, opening by valves. *Seeds* numerous, ſmall, adhering to a columnar receptacle.

Eſſ. Ch. *Cor.* bell-ſhaped, cloſed at the bottom by valves bearing the ſtamens. *Stigma* two, three, or five-cleft. *Capſule* inferior; two, three, or five-celled.

*Obſ.* What Linnæus calls the valves of the nectary are conſidered by Gærtner, Juſſieu, and La Marck, ſimply as connivent dilatations of the filaments, forming a kind of vault over the receptacle. Dr. Smith drops the idea of a nectary, and ſays, that the bottom of the corolla is cloſed by ſtameniferous valves.

* *Calyx* five-cleft. *Capſules* top or egg-ſhaped.

† *Leaves* almoſt ſmooth, not harſh to the touch.

Sp. 1. C. *ceniſia*, Linn. Sp. Plant. Supp. p. 1669. Willd. 1. Mart. Mil. 1. Lam. Enc. 1. Illuſt. 2489. Allion. Ped. 35. Tab. 5. f. 1. Hall. Helv. n. 696. "Stems one-flowered; leaves egg-ſhaped, entire, ſomewhat ciliated." *Root* perennial, creeping, often a foot long, fibrous. *Stems* ſimple, ſmall, weak, about two inches high. *Root-leaves* about an inch long, roundiſh-ſpatule-ſhaped, entire, nearly ſmooth. *Stem-leaves* oblong-egg-ſhaped, ſlightly hairy, ſeſſile. *Flower* blue, terminal, large in proportion to the ſize of the plant; *calyx* rough, with ſhort, white hairs. A native of the Alps about mount Cenis, introduced into England in 1755, by Dr. Fothergill and Dr. Pitcairn. 2. C. *veſula*, Willd. 38. Mart. 69. Lam. Illuſt. 2490. Allion. pedem. n. 397. Tab. 7. fig. 1. "Stem one-flowered, nearly naked; leaves ſmooth, oval, toothed; calyx ſmooth." *Root* perennial. *Stem* about ſix inches high, round. *Root-leaves* numerous, petioled, decurrent, acute, nerved beneath. *Calyx* cleft beyond the middle. *Corolla* ſpreading. Found by Allioni at the foot of mount Veſulo in Piedmont. 3. C. *Bellardi*, Willd. 3. Mart. 68. Lam. Illuſt. 2491. Allion. Ped. n. 396. Tab. 85. fig. 5. "Stem one-flowered, nearly naked; leaves petioled, elliptic lanceolate, toothed." *Root* perennial. *Stem* an inch and a half high, erect, rather firm, round, ſmooth. *Leaves* drawn to a point at each end, deep green, roughiſh, firm, and not juicy. *Flower* blue, upright; *calyx* ſmooth, cleft beyond the middle; ſegments lanceolate-linear, not expanded. A native of Piedmont. 4. C. *uniflora*, Linn. Sp. Pl. 1. Flor. Lap. Tab. 9. fig. 5, 6. Willd. 2. Mart. 2. Lam. Enc. 2. Illuſt. 2492. "Stem one-flowered; calyx equalling the corolla." *Root* perennial. *Stem* ſimple, about three inches high, upright. *Root-leaves* oblong-egg-ſhaped, obtuſe; *ſtem-leaves* longer, lanceolate-linear. *Flower* blue, terminal, nodding. The whole plant ſlightly hairy. A native of mountains in Lapland. 5. C. *hederacea*, Linn. Sp. Pl. 38. Willd. 82. Mart. 53. Lam. Enc. 5. Illuſt. 2493. Mor. hiſt. 2. p. 456. Sect. 5. Tab. 2. fig. 18. Flor. Dan. Tab. 330. bad. Eng. bot. 73. "Leaves heart-ſhaped, five-lobed, petioled, ſmooth; ſtem flaccid." *Root* perennial, fibrous, ſmall. *Stems* procumbent, creeping, wide-ſpreading, ſlender, branched, ſmooth, leafy. *Leaves* oppoſite or alternate, tender, ſmooth, with the exception of a few ſcattered hairs. *Flowers* pale blue, terminal and axillary, nodding, ſome withering after they are gathered. *Capſule* ſmall, hemiſpherical. A native of England, Denmark, France, and Spain, in moiſt ſhady places. Linnæus, without ſufficient reaſon, ſuppoſed it a hybrid plant, from ſome campanula impregnated by Veronica hederifolia. 6. C. *cochlearifolia*, Lam. Ene. 4. Illuſt. 2494. Willd. 73. Barrel. ic. 454. "Stems ſimple, one-flowered; root-leaves roundiſh-heart-ſhaped, ſcolloped, on long petioles; ſtem-leaves ſmaller, ſomewhat ſpatula-ſhaped, acute; flower drooping." *Stems* three inches long, leafy, ſimple, weak. *Root-leaves* numerous, ſmooth, ſcarcely four or five lines broad. *Flowers* blue; *calyx* very ſhort, with five acute teeth. A native of the Italian Alps. 7. C. *Elatines*, Linn. Sp. Pl. 37. Willd. 80. Mart. 52. Lam. Enc. 5. Ill. 2495. Allion. Ped. n. 422. Tab. 7. fig. 1. Barrel. ic. 453? "Leaves heart-ſhaped, toothed, pubeſcent, petioled; ſtems proſtrate; peduncles capillary, many-flowered." *Root* perennial. *Stems* many, generally ſimple, round, pubeſcent, ſpringing from the fiſſures of rocks. *Leaves* alternate, on long petioles. *Racemes* axillary, with about three flowers, ſometimes branched. *Flowers* purple, cleft half way down; ſegments lanceolate, revolute. All the flowers have a linear bracte except the upper one. The whole plant is very milky and pubeſcent, with ſhort hairs. A native of Piedmont at the foot of the Alps. 8. C. *pulla*, Linn. Sp. Pl. 2. Willd. 4. Mart. 3. Jacq. Obſ. 1. p. 30. Tab. 18. Auſt. 3. Tab. 285. "Stems one-flowered; ſtem-leaves egg-ſhaped, ſcolloped; flower drooping." *Root* perennial, ſmall, creeping. *Stems* five or ſix inches high, ſlender, upright, zigzag; ſometimes having one or two flowering branches, each with a ſingle flower. *Root* and *ſtem-leaves* egg-ſhaped, obtuſe, petioled. *Flower* deep blue, terminal; *calyx* ſmooth. There is a variety with roundiſh leaves, and more than one flower. A native of mountains in Auſtria, Stiria, and Aragon. 9. C. *rotundifolia*, Linn. Sp. Pl. 3. Willd. 12. Mart. 4. Lam. Enc. 7. Illuſt. 2498. Curt. Flor. Lond. 4. 21. Eng. Bot. 866. "Root-leaves kidney-ſhaped; upper leaves linear." *Root* perennial, branched, ſomewhat woody. *Stems* ſeveral, from two or three inches to a foot or more in height, rather upright, but weak, round, ſmooth, milky, branched. *Leaves* ſmooth; root-leaves petioled, generally toothed, but ſometimes quite entire; ſtem-leaves near the baſe lanceolate and toothed; near the ſummit linear and entire. *Flowers* blue, ſometimes white, nodding; ſegments of the calyx linear, ſmooth, grooved, expanding horizontally when out of bloſſom; valves of the nectary fringed, pointed, white. The root-leaves from which this ſpecies, rather inconveniently, and, indeed, ſomewhat improperly, takes its name, are ſeldom obſerved, being uſually concealed among the ſurrounding graſs and leaves of other plants, and withering away as the plant advances to maturity. The juice of the flowers ſtains blue, but, with the addition of alum, produces a green pigment. It varies ſo much from ſoil and ſituation, that authors differ greatly from each other with reſpect to what are only varieties, and what are really diſtinct, though kindred ſpecies. Willdenow aſſerts, that C. *rotundifolia* of Allioni, (Flor. Ped. n. 398. Tab. 47. fig. 2.) quoted by Martyn, is certainly a diſtinct ſpecies, ſince it appears, from Allioni's figure, to be very different from *rotundifolia* of Linnæus in the form both of its leaves and of its corolla. La Marck ſpeaks of a variety which he has found in Auvergne, which differs in habit from *rotundifolia*, but, upon examination, is found to reſemble it in all its botanical characters, except that its ſtem-leaves are long lanceolate, and narrowed into a petiole at their baſe. 10. C. *pumila*, Curtis, Bot. Mag. 512. (rotundifolia β. Linn. Minor rotundifolia alpina, Bauh. prod. 34. C. puſilla, Jacq. 2. p. 79? C. ceſpitoſa, Lam. Ill. 2497. Enc. C. pulla, γ. "Root-leaves egg-ſhaped, ſcolloped; petioles flattened; flowers in unilateral racemes, drooping." A plant of much humbler growth than rotundifolia. *Root-leaves* never kidney-ſhaped; on ſhort, flattened, not thread-ſhaped, petioles; continuing during the time of flowering, and forming a mat, not diſappearing like thoſe of the preceding ſpecies; lower ſtem-leaves often of the ſame ſhape. It bears a profuſion of flowers, and being a hardy perennial, is particularly ſuited to adorn rock-work. There is a variety with white flowers. According to Curtis, the ceſpitoſa of Scopoli. (n. 225. Tab. 4.) is probably a variety. Profeſſor Martyn has taken it up as a diſtinct ſpecies, though he had before quoted it as a ſynonym under C. rotundifolia β, the pumila of Curtis. Villars, dauph. 2. 500. Hall. helv. n. 702. Bauh. Prod. 34, are alſo quoted by him under both. 11. C. *anguſtifolia*, Lam. Illuſt. 2499. "Stems many-flowered; lower leaves lanceolate, egg-ſhaped, petioled; ſtem-leaves narrow, acute, ſeſſile." A native of the ſouth of France. La Marck aſſerts that though nearly allied to rotundifolia, it is diſtinct, and refers to Gmelin, Sib. 3. tab. 33. 12. C. *ſubuniflora*, La Marck Illuſt. 2500. (Uniflora, Vill. Dauph. 2. p. 500. tab. 10. Linifolia, Willd. 13?) "Lower part of the ſtem ſomewhat hairy; loweſt leaves egg-ſhaped; upper ones narrow-lanceolate; flower terminal, erect. Small abortive flowers are found in the axils of the upper leaves." There is a variety entirely hairy, which La Marck conjectures may be C. valdenſis of Allioni (Flor. Ped. n. 400. tab. 6. fig. 1.) The valdenſis is taken up by Martyn as a diſtinct ſpecies; and C. Scheuchzeri of Villars (Dauph. 2. 503. tab. 103. taken up from Scheuch. it. 454. tab. 14. fig. 1.) is quoted as a ſynonym. Willdenow ſuppoſes the valdenſis of Allioni to be his linifolia, and C. Scheuchzeri a variety.

13. C. *pubeſcens*, Willd. 14. Schmidt. Bohem. n. 167. "Stem hairy; leaves ſmooth; root-leaves heart-ſhaped; ſtem-leaves oblong, toothed, petioled." *Root* perennial. *Stem* decumbent, angular. *Flowers* ſhort, broad. A native of rocky woods in Bohemia. 14. C. *linifolia*, La Marck Enc. 8. Ill. 2501. "Smooth; ſtem erect, many-flowered; leaves all ſeſſile; the lower ones egg-ſhaped; upper ones lanceolate-linear." *Stem* about a foot high, ſimple, ſmooth. *Leaves* almoſt entirely ſmooth; upper ones entire, acute, a little reſembling thoſe of flax. *Flowers* blue, peduncled, terminal; calyx ſmooth, with five erect, acute ſegments. Found by La Marck in great abundance in the paſtures of Mont d'Or, and, as he ſays, too diſtinct from C. rotundifolia to be confounded with it. 15. C. *diffuſa*, Willd. 81. Lam. Illuſ. 2502. Vahl. Symb. 1. p. 18. Barrel. Ic. 453. "Stems widely ſpreading; leaves petioled, ſerrate-toothed; lower ones heart-ſhaped; upper ones lanceolate; peduncles one-flowered." 16. C. *fragilis*, Mart. 76. Lam. Illuſ. 2541. Cyril. Rar. Neap. Faſc. 1, 32. tab. 11. fig. 2. (C. ſaxatilis, &c. Bar. ic. 453. Rai. Hiſt. 741. n. 21.) "Stems procumbent; branches directed one way, many-flowered; root-leaves kidney-ſhaped, ſcolloped; calyxes angular." A beautiful plant, but extremely brittle, abounding in milk, commonly quite ſmooth, bright green and ſhining, but ſometimes lanuginous. *Root* perennial, brown. *Stems* numerous, crowded, branched towards the middle, hanging down from the clefts in the rocks. *Root-leaves* crowded, petioled; ſtem-leaves alternate, lanceolate, egg-ſhaped. *Flowers* two or three from the ends of the branches; ſegments of the calyx lanceolate, acute; corolla large, bright blue, flat, with a very ſhort tube, and ſharp, deeply cut ſegments; edge of the nectary rough with hairs. A native of the kingdom of Naples, about Salerno and Amalphi, firſt obſerved by Ray, then by Barralier, and finally by Cyrilli. 17. C. *limonifolia*, Linn. Sp. Pl. 33. Willd. 74. Mart. 48. Lam. Enc. 63. Ill. 2539. (C. orientalis, limonii minimi facie, Tourn. Cor. 3.) "Branches ſpreading, undivided; root-leaves elliptical, even, entire; flowers ſeſſile, three together." *Branches* rodlike. *Root-leaves* ſmooth, petioled, not rigid; ſtem-leaves linear, or awl-ſhaped. *Flowers* remote, axillary, generally three together; bractes the length of the germ. A native of the Eaſt. 18. C. *virgata*, Martyn 77. Lam. Ill. 2540. Labillard. Syr. Dec. 2. p. 11. tab. 6. "Branches rodlike; root-leaves lanceolate, ſharp at both ends, toothed, ſomewhat rugged; branch-leaves very ſhort; flowers in pairs, ſeſſile." *Root* biennial. *Stem* upright, a foot or more high, ſtriated, with few leaves; branches ſpreading. *Root-leaves* petioled. *Flowers* remote, commonly two together, blue; bractes the length of the germ; ſegments of the calyx acute; thoſe of the corolla lanceolate, cut almoſt to the baſe. *Capſule* top-ſhaped, angular, three-celled, opening laterally with three holes. A native of mount Libanus. Nearly allied to the preceding, but differing in its deeply cut corolla, and its toothed, rather rugged leaves. 19. C. *patula*, Linn. Sp. Pl. 4. Willd. 22. Mart. 5. Lam. Enc. 9. Ill. 2503. Dill. Hort. Elt. 68. fig. 58. Flor. Dan. 373. Eng. Bot. 42. "Leaves ſtiff; root-leaves lanceolate-oval; panicle ſpreading; calyx toothed." *Root* biennial, ſlender, white. *Stem* a foot and a half high, angular, a little harſh to the touch. *Leaves* rather harſh, ſcolloped; root-leaves obtuſe, petioled; ſtem-leaves ſeſſile, alternate, acuminate, ſlightly toothed, few, diſtant. *Flowers* upright, tapering at the baſe, ſpreading at the border; ſegments of the calyx lanceolate, toothed toward the baſe. A native of Sweden, Denmark, Germany, Switzerland, Piedmont, but it does not appear to have been found in France, nor is it common in England. We have obſerved it growing, not only on the *outſide* of Buddon wood, near Loughborough in Leiceſterſhire, to which Mr. Woodward (Eng. Bot.) confines it, but alſo, and much more abundantly, *within* the wood, in its higher and more rocky part. It has alſo been gathered in ſeveral other midland counties, particularly Warwick, Worceſter, Stafford, Salop, Hereford, and Surry. 20. C. *gracilis*, Willd. 6. Mart. 67. Forſt. Prod. 15. Exot. Bot. p. 87. tab. 45. "Leaves rough, linear-lanceolate; lower ones bluntly toothed. *Stem* round, much branched. *Flowers* ſolitary, terminal; their tube ſhorter than the calyx-ſegments." *Stem* a foot or more high, leafy, two-edged. *Leaves* obtuſe; lower ones oppoſite, the reſt ſcattered. *Flowers* erect, on long peduncles; calyx globoſe, generally rough with deflexed hairs, but in Forſter's original ſpecimen ſmooth; ſegments awl-ſhaped, longer than the body; corolla ſlender, funnel-ſhaped, of a rich blue within, paler without; ſegments acute, fringed, ſometimes only four. *Capſule* three-celled, three-valved at its ſummit. Every part of the herbage rough with a ſhort rigid pubeſcence. Found by Forſter in New Zealand and New Caledonia, raiſed in England from ſeeds brought from New South Wales. 21. C. *vincæflora*, Ventenat. Jard. de Malmaiſon. 12. (Camp. gracilis, Bot. Mag. 691?) "Leaves linear-lanceolate; ſtem round, much branched; peduncles terminal, elongated, one-flowered." Ventenat ſuppoſes his plant and the gracilis of Forſter to be the ſame. Dr. Sims (Bot. Mag.) concurs with him; and there is certainly nothing in the ſpecific character, as given by Ventenat, which can lead to a different opinion; but we have kept them ſeparate, in deference to the judgment of Dr. Smith, who thinks the vincæflora a diſtinct ſpecies, being ſmooth, except ſome ſcattered longiſh briſtles on the leaves; and having a wider flower, with much ſhorter calyx-ſegments, and a leſs globular capſule. The figures in Exotic Botany and the Botanical Magazine are materially different. We have referred that in the latter, though with ſome heſitation, to Ventenat's plant, on account of its wide-ſpreading campanulate, not funnel-ſhaped, flower, which appears of itſelf to form a ſufficient ſpecific diſtinction. The teeth, or, as we ſhould rather call them, ſegments of the calyx, are repreſented in the Botanical Magazine expanding, which would form another good difference, if Dr. Sims had not in the deſcription expreſsly ſtated them to be erect. The ſmoothneſs or roughneſs of the leaves is too variable a character to be of much value. Dr. Smith ſays that the capſule of vincæfolia is leſs globular than that of his Gracilis, but in the Botanical Magazine it is evidently more ſo. Dr. Sims's deſcription differs in ſeveral reſpects from Dr. Smith's. We ſhall tranſcribe the moſt material parts, that future obſervers may be better able to determine the identity or the diverſity of the ſpecies. *Stem* ſquare, hairy, generally decumbent. *Leaves* moſtly oppoſite, toothed, ſomewhat pubeſcent. *Flowers* nodding whilſt in bud, erect when expanded; on long, ſquare, hairy peduncles; calyx egg-ſhaped, ſtriated; teeth awl-ſhaped, erect, diſtant; corolla bell-ſhaped, cut half-way down into five, ſometimes only four, egg-ſhaped, entire ſegments; nectaries or valves three-lobed; anthers oblong, diſappearing almoſt as ſoon as the flower opens; ſtyle erect; ſtigmas three, rolled back, villous. Firſt raiſed by Mr. Curtis, by ſowing the mould that came about the roots of ſome plants imported from New Holland and New Zealand. It flowers during the greateſt part of the ſummer, and is eaſily propagated by ſeeds or cuttings. 22. C. *Rapunculus*, Rampion. Linn. Sp. Pl. 5. Willd. 23. Mart. 6. Lam. Enc. 10. Ill. 2504. Gært. tab. 31. fig. 2. Eng. Bot. 283. (Rapunculus eſculentus, Rai. Syn. 277.) "Leaves waved; root-leaves lanceolate-oval; panicle contracted." *Root* biennial, ſpindle-ſhaped, white, ſweet, eſculent. *Stem* a foot and half

or two feet high, erect, angular, rough, eſpecially on the lower part with deflexed hairs. *Leaves* alternate, ſeſſile, toothed; lower ones rather hairy; upper ones ſmooth. *Bractes* awl ſhaped. *Panicle* erect; its ſide branches bearing from one to three or more flowers. *Flowers* bluiſh purple, or whitiſh; ſegments of the calyx ſometimes toothed, but not ſo much ſo as in patula; corolla inflated, not tapering at the baſe; nectary fringed. *Capſule* crowned with the lanceolate-linear ſegments of the calyx, retuſe, inverſely pyramidal-egg-ſhaped, with three nerves on each of the three blunt angles opening with three lateral holes, a little above the middle. *Seeds* numerous, ſmall, elliptical, lenticularly compreſſed, ſmooth, ſhining, of a pale ruſſet colour. Smith and Gærtner. A native of France, Switzerland, Germany, Piedmont, &c. It has been found in England, about Croydon and Eſher in Surry, old Buckenham caſtle in Norfolk, and Enville in Worceſterſhire. The fleſhy roots and the young leaves are eaten in France in ſallads, and are thought to increaſe the milk in nurſes. The roots are alſo eaten boiled. It was formerly much cultivated in England as an eſculent, but is now neglected. In the time of Parkinſon its roots were boiled till they were tender, and afterwards eaten cold with vinegar and pepper. 23. C. *perſicifolia*, Linn. Sp. Pl. 6. Willd. 26. Mart. 7. Lam. Enc. 11. Ill. 2505. (Rapunculus perſicifolius, Bauh. Pin. 93.) "Root-leaves inverſely egg-ſhaped; ſtem-leaves lanceolate-linear, ſomewhat ſerrated, ſeſſile, remote." *Root* perennial, eſculent. Whole plant, except the germ and capſule, ſmooth. *Stem* two or three feet high, erect, ſimple, angular. *Stem-leaves* ſtraight, acute, diſtant, ſlightly toothed. *Flowers* in a thin ſpike, blue, ſometimes white, on long peduncles; corolla large, broad, ſhort; bractes two to each peduncle. There is a variety found in low woods, with only two or three large flowers, and long narrow leaves. A double variety, both blue and white, is alſo common in gardens, called, in ſome parts of England, Batchelors' Buttons. A native of moſt parts of the continent of Europe. A magnificent, large-flowered variety from South Carolina, imported by Mr. Dickſon of Covent garden, and differing from the European plant only in ſize, is figured in the Botanical Magazine, *397*. It is very hardy and eaſy of culture, increaſing by its roots, which are ſomewhat creeping, and may be parted either in ſpring or autumn. 24. C. *ptarmicæfolia*, Willd. 39. Lam. Enc. 12. Ill. 2506. Tourn. Cor. 4. "Leaves all linear, toothed; ſtems ſimple; flowers erect, ſeſſile." *Stems* ſcarcely a foot high, ſmooth. *Leaves* ſcabrous at their edges with fine ſpinous teeth. *Flowers* alternate, bluiſh, forming a ſpike at the upper part of the ſtem; calyx ſhort, ſmooth; coralla oblong, ſlightly five-cleft: bractes three. Obſerved by Tournefort in Armenia. 25. C. *linarioides*. Lam. Enc. 13. Illuſt. 2507. Willd. 15. "Stem rod-like, panicled: leaves linear: flowers erect, terminal." *General habit* that of Antirrhinum linaria. *Stem* about a foot high, ſlender, ſmooth, ſlightly ſtriated, panicled at the top. *Leaves* numerous, ſcattered, minute, with a few, ſcarcely perceptible teeth. *Flowers* peduncled, ſmall: corolla deeply divided. Found by Commerſon on Monte-Video, near Buenos-Ayres, in South America. 26. C. *pyramidalis*, Linn. Sp. Pl. 17. Willd. 27. Mart. 8. Lam. Encyc. 14. Ill. 2508. (Rapunculus hortenſis: Bauh. pin. 93.) "Leaves ſmooth, even, ſerrated, heart-ſhaped; ſtem-leaves lanceolate: ſtems ruſh-like, ſimple: umbels ſeſſile, lateral." *Root* biennial, oblong, fibrous, milky. *Stems* ſeveral, near four feet high, ſmooth. *Leaves* petioled. *Flowers* blue, ſometimes white, large, open, coming out ſeveral together in lateral and terminal tufts or umbels, on ſhort peduncles: ſegments of the calyx upright, linear. Vigorous plants throw out numerous ſimple, ſhort, lateral branches. A native of Carniola. It is ſometimes cultivated in a pot, and ſet on the hearth of halls, &c. in ſummer, and by ſpreading the upright ſtems on a flat frame compoſed of ſlender laths is formed into the ſhape of a fan, which will nearly cover a common fire-place. 27. C. *americana*, Linn. Sp. 8. but not the ſynonyms which belong to the next ſpecies. Willd. 28. Mart. 9. Hort. Kew. 220. "Leaves heart-ſhaped and lanceolate: petioles ciliated: flowers unilateral; corolla five-cleft, flat." Linn. "Leaves heart-ſhaped and lanceolate, ſerrated; petioles of the lower ones ciliated: flowers axillary, ſeſſile; corolla five-cleft, flat; ſtyle longer than the corolla." Hort. Kew. *Root* annual. *Stem* and *germs* ſmooth. *Flowers* three or four from the axil of each leaf or bracte: corolla ſmall. Linn. A native of Pennſylvania, introduced into England in 1763, by Mr. J. Bartram. 28. C. *nitida*, Willd. 29. Mart. 74. Hort. Kew. 1. 221. L'Herit. Sert. Ang. (C. planiflora, Lam. Enc. 15. Ill. 2509. C. minor Americana, Herm. Lugd. 107. Trachelium minus Americanum: Dodart. Mem. 4. p. 119. tab. 118.) "Leaves oblong, ſcolloped, even; ſtem-leaves lanceolate, nearly entire; corollas bell-wheel-ſhaped. Hort. Kew. "Leaves oblong, ſcolloped, rigid, ſeſſile: flowers erect, flat." Lam. *Root* perennial. *Stems* five or ſix inches high, often ſimple, ſtraight, ſtiff, a little ſtriated. Stem-leaves ſmooth, green, gradually diminiſhing to the top of the ſtem. *Flowers* blue or white, one or two in each axil of the upper leaves: calyx ſhort; ſegments oval-acuminate. La Marck doubts whether it be ſpecifically diſtinct from C. americana, though he acknowledges that it differs from it in having no heart-ſhaped leaves, nor ciliated petioles; and in the flowers not being unilateral: the laſt circumſtance, however, is omitted in the ſpecific character of C. americana, drawn up for the Hortus Kewenſis. A native of America, deſcribed by La Marck from a living plant in the royal garden at Paris. 29. C. *ſtyloſa*, Lam. Enc. 16. Ill. 2510. Willd. 35. Gmel. Sib. 3. tab. 27. good. "Leaves petioled, ſomewhat heart-ſhaped, acutely ſerrated: flowers ſmall, nodding, ſtyle longer than the corolla." *Stem* a foot high or more, ſimple, and, like all other parts of the plant, ſmooth. *Leaves* ſcattered, acuminate, decurrent along the petiole with a ſlight membrane: bractes lanceolate and nearly ſeſſile. *Flowers* oblong, bluiſh, in a terminal panicle: border obtuſe: ſtyle very long: ſtigma club-ſhaped, ſlightly three-cleft. A native of Siberia, ſent to the royal garden at Paris, under the name of C. lilifolia. 30. C. *periplocifolia*. Lam. Enc. 17. Ill. 2511. "Leaves heart-ſhaped, obtuſely ſerrated, on long petioles: ſtems aſcending, few-flowered." Reſembling the preceding, but ſmaller, and not with upright ſtems. *Leaves* all petioled, acuminate, ſmooth, a little toothed or ſcolloped. *Flowers* terminal, pale blue, reſembling thoſe of C. ſtyloſa. A native of Siberia, cultivated in the royal garden at Paris. 31. C. *lilifolia*, Linn. Sp. Pl. 9. Willd. 30. Mart. 10. Lam. Enc. 18. Ill. 2512. Amm. Ruth. p. 11. n. 17. Gmel. Sib. 3. p. 143. tab. 26. "Leaves lanceolate; ſtem-leaves acutely ſerrated: flowers panicled, nodding." *Root* perennial. It varies in its form and ſize, and in the number and colour of its flowers; but may in all caſes be diſtinguiſhed from the two immediately preceding by its ſeſſile ſtem-leaves. A native of Siberia, from the Iaick eaſtward to the confines of China. The roots are eaten by the inhabitants boiled and raw. 32. C. *azurea*, Bot. Mag. 551. Solander MSS. in the poſſeſſion of ſir Joſeph Banks. "Leaves oblong, egg-ſhaped, ſeſſile, ſerrated: ſtem ſimple, angular: flowers panicled." Sol. *Root* perennial. *Stem* erect, quadrangular, with raiſed, ſomewhat cartilaginous angles. *Root-leaves*

*leaves* few, petioled, heart-egg-ſhaped; with a few, thinly ſcattered hairs underneath, chiefly about the margin: *ſtem-leaves* alternate, acute, thinly haired. *Flowers* blue: peduncles long, thread-ſhaped, alternate, axillary, once or twice divided; pedicels nodding, with linear bractes: calyx pentagonal. A native of Switzerland. It flowered in the botanic garden at Chelſea, in 1778. 33. C. *carpatica*, Linn. jun. Supp. p. 140. Willd. 16. Mart. 16. Jacq. Hort. 1. tab. 57. Bot. Mag. 117. "Leaves heart-ſhaped, ſerrated, ſmooth, petioled: peduncles elongated; calyx reflexed, glutinous." *Root* perennial. *Stem* herbaceous, milky, a little branched; in gardens much branched, and many-flowered. *Flowers* blue: calyx five-cleft; ſegments linear-lanceolate, acuminate, a little reflexed, beſet with glutinous glands. Mr. Curtis obſerves, that it deſerves to be better known and more cultivated, being large and ſtrong, and like many other Alpine plants, well calculated to decorate rock-work and the borders of the flower garden. A native of the Carpatian Alps. Sent to the royal garden of Kew, in 1774, by Profeſſor Jacquin. 34. C. *grandiflora*, Linn. jun. Supp. p. 140. Willd. γ. Mart. 17. Jacq. Hort. 3. p. 4. tab. 3. Bot. Mag. 252. (C. gentianoides: Lam. Encyc. 19. Ill. 2513.) "Leaves lanceolate, egg-ſhaped, ſerrated, nearly ſeſſile: branches one-flowered: flowers top-ſhaped, ſpreading: ſtigma five-cleft." *Root* perennial, white, ſpindle-ſhaped, and branched. *Stems* few, about a foot high, feeble, ſimple, or furniſhed at the ſummit with three or four ſmall branches. *Leaves* near two inches long, ſometimes growing in threes, ſmooth, bright green above, a little glaucous and finely veined beneath. *Flowers* large, of a beautiful blue, terminal, and ſometimes two or three from the upper axils, green and elegantly pear-ſhaped before expanſion, reſembling an air-balloon, whence it has ſometimes been called the balloon plant. No holes in the capſule. It was ſuſpected by the younger Linnæus to be only a variety of C. carpatica, but Jacquin determined it to be a diſtinct ſpecies. A native of Siberia and Tartary, introduced into England in 1782, by Mr. John Bell. 35. C. *rhomboidalis*, Linn. Sp. Pl. 10. Lam. Enc. 20. Illuſ. 2514. (C. rhomboidea: Mart. 11. Willd. 32. C. caule ſimplici, &c.: Hall. helv. n. 693. C. drabæ minoris folio: Bauh. p. 94. prod. 93. Rapunculus Teucrii folio: Bar. ic. 567. Bocc. Muſ. 75. tab. 61.) "Leaves rhomboidal, ſerrated; ſpike often unilateral; calyx-ſegments capillary." *Root* perennial, creeping. *Stems* from ſix to ſixteen inches high, upright, ſlender, angular, almoſt ſmooth. *Leaves* ſeſſile, ſcattered, with a few ſhort hairs. *Flowers* blue, in a ſhort, looſe ſpike: calyx ſmooth, with awl-ſhaped, entire ſegments. *Capſule* ſmall, ſcarcely three inches long, inverſely pyramidal, not egg-ſhaped, triangular; angles rounded, thick, three-nerved; interſtices narrow, depreſſed; holes juſt below the baſe of the calyx. *Seeds* ſmall, ruſſet, ſhining. Lam. and Gært. A native of Italy, Switzerland, and the ſouth of France. 36. C. *aſteroides*, Lam. Ill. 2515. "Stem angular, rod-like; leaves egg-ſhaped, acuminate, finely ſerrated, remote; flowers ſeſſile, axillary and ſpiked." *Corolla* widely ſpreading. *Calyx* reflexed. *Style* exſerted, aſcending. *Stigma* three-cleft. Cultivated by M. le Monnier at Paris; native country unknown. 37. C. *Alpini*, Linn. Sp. Pl. p. 1669. Lam. Enc. 21. Illuſ. 2516. (C. rhomboidea β.: Willd. Mart. pyramidalis minor: Alp. exot. 340.) "Leaves lanceolate, ſerrated; lower ones petioled; upper ones ſeſſile: flowers nodding: ſtyle exſerted." Lam. *Root* perennial. Larger and more branched than C. rhomboidalis, and diſtinguiſhed from it by its petioled lower leaves and long ſtyle. A native of Italy near Baſſano. 38. C. *criſpa*, Lam. Enc. 22. Ill. 2517. (C. orientalis, foliorum crenis amplioribus: Tourn. Cor. 3.) "Leaves even, petioled, ſomewhat heart-ſhaped, doubly ſerrated, gaſhed: ſtem ſimple: flowers lateral and terminal, ſpreading." *Stems* three or four, about a foot high, ſimple, round, ſmooth, rather thick. *Leaves* curled; lower ones interruptedly decurrent on long petioles. *Flowers* on ſhort peduncles; in an upright, long, leafy ſpike: corolla ſhort, very open; with five oval, rather acute ſegments: ſtigma five-cleft. Found by Tournefort in Armenia; deſcribed by La Marck from a ſpecimen in the Herbarium of Juſſieu, and from an original drawing by Aubriet. 39. C. *enſifolia*, Lam. Enc. 23. Ill. 2518. Willd. 31. "Stem ſhrubby: leaves ſword-ſhaped, ſerrated, ſmooth: flowers panicled, nodding." *Stem* in its lower part woody, ſimple or occaſionally a little branched, ſcarred with the marks of fallen leaves, and crowned with numerous cloſe-ſet leaves in a roſaceous form, which are from two to three inches long, and from four to five lines broad, ſimilar to thoſe of Yucca or Pandanus, and ſtriated with longitudinal nerves. From the midſt of theſe leaves riſes a ſmooth ſtem about ſix inches high, clothed with alternate, ſeſſile leaves, reſembling thoſe below, but ſmaller. From the axil of each ſtem-leaf ſprings a ſhort one-flowered branch furniſhed with one or two ſmall leaves, which give the whole a panicled appearance. *Flowers* drooping: calyx ſmooth. Found by Commerſon on the Volcano in the iſle of Bourbon. 40. C. *aurea*, Linn. jun. Supp. p. 141. Willd. 68. Mart. 18. Lam. Enc. p. 590. Ill. 2519. "Capſules five-celled: leaves elliptical, doubly ſerrated, ſmooth: flowers ſomewhat panicled: ſtem, ſhrubby, fleſhy." *Root* perennial. *Stems* growing cloſe to the rocks. *Calyx* coloured. Tube of the *corolla* diſtinct from the calyx: ſegments of the border reflexed. *Stigma* five-cleft. Diſcovered in the iſland of Madeira by Maſſon, and introduced at Kew in 1777. 41. C. *verticillata*, Linn. jun. Supp. p. 141. Wild. 11. Mart. 61. Lam. Enc. 24. Ill. 2520: Pallas it. vol. iii. p. 719. tab. g* fig. 1. German edition, vol. iv. p. 376. tab. 34. French Tranſlation. "Leaves five or ſix in a whorl, lanceolate, ſerrated: flowers in whirls." *Root* perennial, thick. *Stems* numerous, about a foot high, erect. *Leaves* about ſix in a whorl, nearly upright, ſtiff, ſtrongly nerved. *Flowers* blue, on the upper part of the ſtem above the whorls of leaves, drooping, many in a whorl, on ſhort peduncles: whirls about five, diſtant from each other: bractes awl-ſhaped, rather aſcending: calyx ſmall, with briſtle-ſhaped ſegments: ſtyle almoſt twice the length of the corolla. A native of Dauria. 42. C. *Zoyſii*. Willd. 5. Lam. Ill. 2521. Jacq. ic. 2. tab. 334. Hoſt. Syn. 105. "Stems tufted, few-flowered: leaves ſmooth, very entire; root-leaves petioled, roundiſh egg-ſhaped; ſtem-leaves oblong-inverſely egg-ſhaped, ſeſſile." *Root* perennial. *Stems* two or three inches high. *Corolla* cylindrical, nodding: orifice bearded. A native of rocky mountains in Auſtria. 43. C. *tenella*, Linn. jun. Supp. p. 141. Willd. 79. Mart. 19. Lam. Enc. p. 390. Ill. 2522. Thunb. Prod. (Lobelia tenella: Linn. Mant. 120. Syſt. Nat. 28. Lightfootia oxycoccoides: l'Herit. Sert. Ang. tab. 4.) "Stems diffuſe, thread-ſhaped: leaves egg-ſhaped, generally with one tooth, reflexed: flowers ſolitary, terminal." *Root* perennial. *Stems* five or ſix inches long, regularly branched; branches ſimple. *Leaves* ſmall, crowded, ſeſſile, gloſſy, obtuſe, channelled. *Flowers* ſmall, few, lateral, on ſhort peduncles near the ſummit of the branches: calyx gloſſy; ſegments acute: corolla five-cleft. Found at the Cape of Good Hope by Thunberg and Sonnerat. 44. C. *ſeſſiliflora*, Linn. jun. Supp. p. 139. Willd. 21. Mart. 57. Lam. Enc. p. 590. (Lightfootia ſubulata l'Heritier ſert. tab. 5. ?.) "Stem proſtrate; leaves linear-awl-ſhaped, entire; flowers axillary, ſolitary, ſeſſile." Found by Thunberg at the Cape of Good Hope. 45. C. *faſciculata*, Linn. jun. Supp. p. 139. Willd. 25. Mart. 58. Lam. Enc. p, 590. Ill. 2524, "Stem ſhrubby; leaves ſmall, egg ſhaped, with one or two teeth, recurved; flowers glomerated, terminal." Found by Thunberg and Sonnerat at the Cape of Good Hope. 46. C. *Lobelioides*, Linn. jun. Supp. p. 140. Willd. 17. Mart. 15. Lam. Enc. p. 590. Ill. 2525. "Stems round, ſtiff, and ſmooth; leaves linear-lanceolate, toothed; corolla funnel-ſhaped." *Root* annual. *Stems* much branched. *Leaves* ſeſſile. *Flowers* very ſmall, pale purple; calyx with three or five egg-ſhaped, obtuſe diviſions; corolla twice as long as the calyx; tube round, gradually widened; ſegments of the border three or five, erect; ſtamens three or five. *Capſule* two-celled. In general habit, tenderneſs, mode of diviſion and infloreſcence it reſembles a Lobelia, Linn. jun. Found by Maſſon in the iſland of Madeira; introduced into England in 1777. 47. C. *poroſa*, Linn. jun. Supp. p. 142. Willd. 18. Mart. 20. La Marck Enc. p. 590. Thunb. prod. 39. "Root-leaves inverſely egg-ſhaped; ſtem-leaves lanceolate; ſtem rough, with points; flowers in racemes." This plant is diſtinguiſhed by the minute pores on the ſtem, which are directed not downwards but upwards. *Stem* about a foot high, round; branches numerous, upright, ſhort. *Flowers* ſmall, a little nodding; calyx half the length of the corolla, even; ſegments lanceolate. 48. C. *undulata*, Linn. jun. Supp. p. 142. Willd. 19. Mart. 21. Lam. Enc. 590. "Leaves lanceolate, toothed, waved; flowers nearly ſolitary, peduncled." *Stem* a foot and half high, upright, ſlender, ſmooth, a little branched near the top. *Leaves* ſeſſile, a little decurrent, reflexed at the edges, repand, nearly even. *Flowers* the ſize of thoſe of rotundifolia; calyx even; ſegments ſhort, acuminate. 49. C. *capillacea*, Linn. jun. Supp. p. 139. Martyn 13. "Herbaceous, upright; leaves thread-ſhaped, ſmooth; panicle terminal; flowers alternate; capſules ſmooth." 50. C. *linearis*, Linn. jun. Supp. p. 140. Willd. 20. Mart. 14. "Herbaceous, upright; leaves linear, entire, ſmooth; flowers drooping; calyx the length of the corolla; capſule hiſpid." 51. C. *unidentata*, Linn. jun. Supp. p. 139. Willd. 24. Mart. 12. "Stems upright, ſimple, ſmooth; leaves lanceolate, ſmooth, with one tooth on each ſide; panicle divaricated, leafy." 52. C. *adpreſſa*, Linn. jun. Supp. p. 139. Willd. 47. Mart. 60. "Stem herbaceous, upright; leaves lanceolate, toothed, recurved, ciliated at the baſe, preſſed cloſe to the ſtem; panicle twice compound." 53. C. *procumbens*, Linn. jun. Supp. p. 141. Willd. 78. Mart. 62. "Stem dichotomous, diffuſed; leaves inverſely-egg-ſhaped, ſcolloped, obtuſe; flowers ſolitary, erect." 54. C. *cinerea*, Linn. jun. Supp. p. 139. Willd. 51. Mart. 26. Thun. Prod. 38. "Leaves lanceolate, waved, hairy, entire; ſtem angular, hiſpid; flowers in racemes." The laſt eight were found by Thunberg at the Cape of Good Hope. 55. C. *triphylla*, Willd. 10. Mart. 63. Thunberg, flor. jap. 87. "Leaves by threes, linear; flowers by threes in whorls." *Root* perennial, ſpindle-ſhaped. *Stem* herbacous, erect, ſmooth. *Leaves* an inch long, ſeſſile, acute, entire, reflexed at the edge, expanding, ſmooth. *Flowers* axillary, peduncled; peduncles capillary, ſeldom more than one flowered, three times the length of the leaves. 56. C. *tetraphylla*, Willd. 9. Mart. 64. Thunb. flor. jap. 87. "Leaves by fours, oblong, ſerrated." *Stem* two feet high, obſcurely angular, jointed, ſmooth, ſimple at bottom, panicled at top; branches four, oppoſite and alternate, wand-like, diffuſed, obſcurely quadrangular, ſmooth; the upper ones ſhorter, capillary. *Leaves* an inch or more long, the length of the internodes, ſeſſile, attenuated towards the baſe, acute, ſmooth, erect; green above, pale beneath, with a ſtrong midrib. *Flowers* on the branches numerous, drooping, on capillary peduncles; bractes briſtle-ſhaped, ſmooth; corolla whitiſh; anthers linear; ſtyle double the length of the corolla, ſtigma trifid.

† Leaves harſh to the touch.

57. C. *glauca*, Willd. 7. Mart. 65. Thunb. flor. jap. 88. "Leaves ſeſſile, egg ſhaped, ſerrated, glaucous beneath; ſtem angular, panicled; peduncles one-flowered." An under-ſhrub. *Stem* two feet high, erect, ſmooth; branches erect, zigzag, ſomewhat faſtigiate, angular, ſmooth. *Leaves* ſcattered, acute, a little reflexed at the edge, ſcabrous, netted; lower ones larger, expanding, upper gradually leſs, erect, about an inch long. *Flowers* axillary on the upper part of the branches; peduncles an inch long, erect; bractes one or two on a peduncle, alternate, lanceolate, reſembling the leaves; calyx ſomewhat angular, glaucous; ſegments lanceolate, reflexed; corolla large, blue. 58. C. *marginata*, Willd. 44. Mart. 66. Thun. jap. 89. "Leaves lanceolate, waved, ſerrated, bordered; branches weak; flowers terminal, ſolitary." *Stem* thick at the baſe, rather woody, decumbent; branches numerous, about ſeven inches long, capillary, rather erect, a little ſubdivided, ſtriated, ſmooth. *Leaves* on the lower part of the branches half an inch long, ſeſſile, alternate, white edged, hiſpid with white hairs. *Flowers* terminal, ſolitary. The laſt four were obſerved by Thunberg in Japan. 59. C. *paniculata*, Linn. jun. Supp. p. 139. Willd. 50. Mart. 59. Thunb. Prod. 39. "Leaves lanceolate, waved, hairy; ſtem angular, hiſpid; flowers in racemes." *Stem* herbaceous, panicled; branches divaricated. *Leaves* entire. A native of the Cape of Good Hope. 60. C. *latifolia*, Giant throat-wort, Linn. Sp. Pl. 11. Willd. 33. Mart. 22. Lam. Enc. 25. Ill. 2526. Eng. Bot. 302. "Leaves egg-lanceolate; ſtem quite ſimple, nearly round; flowers ſolitary, peduncled; calyxes ſmooth; fruit drooping." *Root* perennial, milky. *Stem* three or four feet high, erect, ſlightly angular, ſomewhat hiſpid, many-flowered. *Leaves* large, alternate, nearly ſeſſile, roughiſh, doubly ſerrated. *Flowers* large, blue, ſometimes white, axillary, almoſt always ſolitary, erect; calyx ſmooth, ſerrated. A native of Sweden, Switzerland, and other parts of Europe; common in Scotland and the north of England, rare in the ſouth. It is ſometimes cultivated in gardens. 61. C. *urticifolia*, Willd. 34. Schmidt. 173. "Stem angular, hiſpid; upper leaves egg-lanceolate, coarſely ſerrated: peduncles one-flowered, axillary, drooping; calyxes hiſpid." It differs from the preceding, chiefly in its hiſpid calyxes; but its ſtem is alſo more hiſpid, and has more prominent angles; its root and lower ſtem leaves are alſo heart-ſhaped, and in that reſpect approach more nearly to C. trachelium. A native of ſhady places in Germany and Bohemia. The urticifolia of Allioni (flor. pedem. n. 406.) taken up by Profeſſor Martyn n. 72., ſeems a different plant, which ought to be placed with a new ſpecific name in the preceding ſubdiviſion. It is thus characterized: "Stem roundiſh, ſimple, upper leaves ſeſſile; ſpike unilateral; peduncles one-flowered; calyxes ſmooth." Plant entirely ſmooth. *Stem* three feet high, ſtreaked. *Leaves* ſoft, egg-lanceolate, unequally and ſharply toothed. *Flowers* ſingle, axillary, on ſhort peduncles towards the top of the ſtem, with linear bractes; calyx five-cleft beyond the middle; ſegments narrow, not reflexed: corolla and calyx nearly equal. A native of Italy in woods. After all, the plants of Schmidt and Allioni are nearly allied to each other, and ſeem to differ chiefly in the comparative length of the calyx and corolla. Both of them may, perhaps, be not improperly conſidered as varieties of C. latifolia. Characters

drawn from the ſmoothneſs or roughneſs of the leaves, though they often afford a good and always an obvious diſtinction, and on that account make convenient ſubdiviſions in a large genus, are ſometimes fallacious, and can ſeldom be oppoſed to each other with rigid exactneſs. 62. C. *Trachelium*, nettle-leaved throat-wort, Linn. Sp. Pl. 16. Will. 41. Mart. 28. Lam. Enc. 26. Ill. 2527. Eng. Bot. 12. "Stem angular; leaves lanceolate-heart-ſhaped, acutely ſerrated; calyxes hiſpid; peduncles axillary, few-flowered." *Root* perennial. *Stem* two or three feet high, ſtiff, hiſpid. *Leaves* petioled, deeply and unequally ſerrated, harſhly rough, generally hiſpid with pungent briſtles. *Flowers* violet-coloured, rather leſs than thoſe of C. latifolia; ſometimes three, but more frequently only one on a peduncle; calyx hiſpid at the baſe and on the edge, but ſometimes ſmooth. A native of many parts of Europe; common in the ſouth, but rare in the north of England. 63. C. *rapunculoides*, Linn. Sp. Pl. 12. Willd. 36. Mart. 23. Lam. Enc. 27. Ill. 2528. Eng. Bot. 1369. "Leaves lanceolate-heart-ſhaped; ſtem branched; flowers ſcattered, unilateral, nodding; calyxes reflexed." *Root* perennial, creeping. *Stem* about a foot high, more or leſs branched, round, rough with deflexed hairs. *Leaves* ſcabrous; lower ones petioled, lower ones ſeſſile. *Flowers* blue, axillary. *Capſule* reſembling that of Rapunculus, but only half as large. *Segments of the calyx* linear, reflexed. *Openings* large at the very baſe of the capſule. *Seeds* elliptical, ſo much compreſſed as to be almoſt flat, plain on one ſide, marked with an elevated longitudinal line on the other, of a yellowiſh bay colour, ſcarcely ſhining. Gært. A native of Switzerland, France, and Auſtria; rare in great Britain, but, as appears from Buddle's herbarium, gathered among yew trees in ſome woods in Oxfordſhire, and found, apparently wild, by Dr. Skrimſhire at Blair in Scotland. 64. C. *bononienſis*, Linn. Sp. Pl. 13. Willd. 37. Mart. 24. Lam. Enc. 28. Ill. 2529. "Leaves egg-lanceolate, ſcabrous beneath, ſeſſile; ſtem panicled." *Root* perennial, large, woody. *Stem* with the habit of verbaſcum nigrum, three feet high or more, erect, rough. *Leaves* ſeſſile, almoſt heart-ſhaped, ſlightly toothed, covered with white hairs beneath. *Flowers* violet-colour, terminating the branches in a kind of ſpike, axillary; lower ones three together, on ſhort peduncles; upper ones ſingle, ſometimes two, ſeſſile. A native of Italy, Carniola, Switzerland; introduced into England in 1773 by John Earl of Bute. 65. C. *graminifolia*, Linn. Sp. 14. Willd. 40. Mart. 25. Lam. Enc. 29. Ill. 2530. "Leaves linear-awl ſhaped; head terminal." *Root* perennial, divided at the crown into ſeveral trunks, each producing a tuft of ſtraight, long, graſslike leaves, ciliated at their baſe. *Stems* ſimple, ſcarcely longer than the root-leaves. *Stem-leaves* alternate, rather embracing the ſtem. *Flowers* blue, five or ſeven together, in a head; bractes egg-ſhaped, acuminate; ſtigma twocleft. 66. C. *glomerata*, little Canterbury bells, Linn. Sp. Pl. 17. Willd. 42. Mart. 29. Lam. Enc. 30. Ill. 2531. Eng. Bot. 90. "Stem angular, ſimple; flowers ſeſſile; moſt of them collected into a head, a few ſolitary, and axillary within the upper leaves; leaves egg-ſhaped, ſcolloped." *Root* perennial, woody. *Stem* a foot high, erect, roundiſh, rather rough, ſeldom if ever branched, unleſs firſt eaten down by cattle. *Leaves* hairy, pale beneath; root-leaves a little heart-ſhaped, on long petioles; ſtem-leaves half embracing the ſtem. *Flowers* blue, purple, or white. A native of lime-ſtone and chalky ſoils in England, France, and other parts of Europe. 67. C. *petræa*, Linn. Sp. Pl. 20. Willd. 46. Mart. 32. Lam. Enc. 31. Ill. 2532. Bar. ic. 890. (Trachelium majus petræum; Pon. bald. 161.) "Stems ſimple, rough; leaves oblong-egg-ſhaped, hairy, ſeſſile; head terminal." Nearly allied to the preceding, but more hairy. *Stem* one or two feet high, erect, rough. *Leaves* all oblong, harſh, deep green above, whitiſh and cottony beneath; ſtem-leaves not half embracing the ſtem. Found firſt by Pona on mount Baldo: a native alſo of Piedmont, Sileſia, &c. 68. C. *Cervicaria*, Linn. Sp. Pl. 18. Willd. 43. Mart. 30, Lam. Enc. 32. Ill. 2533. "Hiſpid; flowers ſeſſile; head terminal; leaves lanceolate-linear, waved, ſcolloped." *Root* biennial, eſculent. *Stem* about a foot high, ſimple, or a little branched. *Leaves* ſtraight, almoſt linear, rough with hairs. *Flowers* blue or white, moſt of them in a head, a few axillary. A native of woods on the continent of Europe; introduced into England in 1783 by Dr. Pitcairn. 69. C. *thyrſoidea*, Linn. Sp. 19. Willd. 45. Mart. 31. Lam. Enc. 33. Ill. 2534. "Hiſpid; raceme oblong egg-ſhaped, terminal; ſtem quite ſimple; leaves lanceolate-linear." *Root* biennial, large, woody. *Stem* eight or ten inches high, erect, rough with white hairs. *Root leaves* tufted, rough, lanceolate-egg-ſhaped. *Stem-leaves* numerous, upright, ſcattered, hairy, a little harſh to the touch. *Flowers* yellowiſh white, very numerous, denſely diſpoſed in a kind of thyrſe; corolla hairy. A native of Auſtria, Switzerland, and the ſouth of France. 70. C. *lanuginoſa*, Lam. Enc. 34. Ill. 2535. (C. peregrina: Linn. Mant. Willd. 52?) "Hiſpid-lanuginous: leaves egg-ſhaped, wrinkled, ſcolloped, narrowing into a petiole: ſtem ſimple; flowers nearly ſeſſile, erect, open." *Stem* a foot high, erect, round, thickly covered with ſeparate white hairs. *Root-leaves* rough on both ſides, pale green above, whitiſh beneath, a little reſembling thoſe of the primroſe: *ſtem-leaves* ſmaller, alternate; the upper ones ſeſſile and rather acute. *Flowers* lateral and terminal, ſolitary, blue: calyx hiſpid, a little ſhorter than the corolla; ſegments lanceolate: corolla ſhort, very open: ſtyle not longer than the corolla: ſtigma three cleft. Cultivated for a long time in the royal garden at Paris, and ſuppoſed to be a native of Tartary. The peregrina of Linnæus ſprang up in ground ſown with ſeeds from the Cape of Good Hope, but it was probably mixed with them by accident. 71. C. *tomentoſa*, Lam. Enc. 35. Ill. 2536, (C. foliis profunde inciſis, tomentoſa tota & incana, Tourn. Cor. 3.) "Root-leaves long, ſpatula-ſhaped, ſcolloped; upper ones wedge-ſhaped; flowers peduncled, ſomewhat ſpiked; calyx downy." The whole plant covered with a fine white down. *Stem* round. *Flowers* oblong, in a looſe, ſometimes unilateral ſpike, on ſhort peduncles: calyx half the length of the corolla. Deſcribed by La Marck from a dried ſpecimen in the herbarium of Juſſieu. Native country unknown. 72. C. *argentea*. Lam. Enc. 36. Ill. 2537. (C. leucoii folio: Tourn. Cor. 3.) "Leaves oblong, narrow, ſilvery-white with down; ſtem panicled: branches one-flowered." *Stem* three or four inches high. *Root-leaves* numerous, a little enlarged towards their ſummit, ſcarcely an inch long, entire. *Stem-leaves* almoſt linear. *Flowers* terminal. A native of Armenia, preſerved in the herbarium of Juſſieu. 73. C. *calaminthifolia*, Lam. Enc. 37. Ill. 2538. (C. ſaxatilis, foliis crenatis & veluti rugoſis: Tourn. Cor. 3.) "Pubeſcent: ſtem branched, decumbent: ſtem-leaves roundiſh egg-ſhaped, ſcolloped, nearly ſeſſile; thoſe on the branches ſmall, acute: corolla pubeſcent on the outſide." *Stem* ſcarcely a foot long. *Stem leaves* ſpatula-ſhaped, like thoſe of the daiſy. *Flowers* terminating and axillary: corolla a little tubular. Found by Tournefort in the iſland of Naxos; deſcribed from a dried ſpecimen in the herbarium of Juſſieu, and an original drawing by Aubriet. 74. C. *hiſpidula*, Linn. jun. Supp. p. 142. Willd. 49. Mart. 27. Lam. Enc. 40. Ill. 2542. "Hiſpid: flowers erect; calyx the length of the corolla." *Root* annual. *Stem* about four inches high, branched, eſpecially near the top. *Leaves* alternate, linear, acuminate, ciliated, eſpecially the midrib. *Flowers* nearly ſeſſile, terminal: ſegments of the calyx linear, ciliated: corolla funnel-ſhaped: ſtigma three-cleft. A native of the Cape of Good Hope. 75. C. *capenſis*, Linn. Sp. Pl. 36. Willd. 77. Mart. 51. Lam. Ill. 2543. Bot. Mag. 782. "Leaves lanceolate, toothed, hiſpid: peduncles very long: capſules beſet with ſtiff hairs." *Root* annual. *Stem* round, hairy, branched. *Leaves* waved, oppoſite below, ſcattered near the top. *Flowers* blue, nodding: ſegments of the calyx linear-lanceolate, entire, ſpreading: corolla funnel-ſhaped; tube ſhort, hairy within; ſegments of the border egg-ſhaped, acute: ſtigma five-cleft; ſegments petal-like, egg-ſhaped, ſpreading, deep blue, hiſpid underneath. *Capſule* five-celled, erect, obſoletely ten-angled, opening with five lanceolate valves. *Seeds* flat, ſhining, numerous. A native of the Cape of Good Hope. 76. C. *cernua*, Willd. 53. Thunb. Prod. 39. "Leaves oblong, waved, hairy: flowers terminal, drooping: calyx ſmooth." A native of the Cape of Good Hope. 77. C. *Erinus*, Linn. Sp. Pl. 40. Willd. 85. Mart. 56. Lam. Enc. 38. Ill. 2544. Læf. it. 127. (Rapunculus minor, foliis inciſis Bauh. pin.) "Stem dichotomous: leaves ſeſſile; upper ones oppoſite, three toothed." *Root* annual. *Stem* about ſix inches high. *Root-leaves* oblong; *Stem-leaves* oblong, a little ſpatula-ſhaped. *Flowers* pale blue, ſmall. A native of barren places in Italy, Spain, and the South of France. 78. C. *erinoides*. Linn. Mant. p. 44. Willd. 83. Mart. 54. Lam. Enc. 39. Ill. 2545. "Stems diffuſe; leaves lanceolate, ſlightly ſerrated, decurrent with a ſcabrous edge: flowers peduncled, ſolitary." *Stems* much branched. *Leaves* alternate. *Flowers* terminal, erect; germ not angular: ſtyle three-cleft. According to Linnæus it reſembles lobelia erinoides, and La Marck obſerves that his only ſynonym is Herm. Lugd. 100. tab. 11.; with a mark of doubt, the ſame which he has quoted under Lobelia erinus without ſuch mark, and which is alſo the only one under that ſpecies. Profeſſor Martyn conſiders them as one and the ſame plant, and has accordingly referred C. erinoides to Lobelia erinus; but La Marck, notwithſtanding his remark in the Encyclopedie Methodique, has continued C. erinoides in his Illuſtrations. Said to be a native of Africa. 79. C. *repens*. Mart. 78. Loureiro Cochin. 139. "Stem ſubdivided, creeping: leaves oblong, fleſhy: flowers ſolitary." *Stem* herbaceous, much branched. *Leaves* entire, ſmall, hairy, oppoſite. *Flowers* ſmall, white, ſeſſile, axillary: ſegments of the calyx acute, upright: ſegments of the corolla rounded, acuminate: ſtigma three-cleft. *Capſules* roundiſh triangular, hairy, three-celled, one-ſeeded. A native of Cochinchina.

* * Calyx five-cleft: capſules elongated, priſm-ſhaped.
(Priſmatocarpus: l'Herit. legouiſia: Durande.)

80. C. *fruticoſa*, Linn. Sp. 30. Willd. 69. Mart. 45. Lam. Enc. 60. Ill. 2569. C. africana, ericæ folio Herm. afr. 5. "Capſules five-celled, ſtem ſhrubby; leaves linear-awl-ſhaped: peduncles very long." *Root* perennial. *Flowers* blue, expanded. A native of the Cape of Good Hope. 81. C. *Speculum*, Venus's looking-glaſs. Linn. Sp. Pl. 31. Willd. 70. Mart. 46. Lam. Enc. 61. Ill. 2570. Bot. Mag. 102. "Stem much branched, diffuſe: leaves oblong, ſlightly ſcolloped: flowers ſolitary." *Root* annual. *Stems* from ſix to ten inches high. *Leaves* ſmall, ſeſſile. *Flowers* purple, inclining to violet, peduncled, terminal, folding up in the evening into a pentagon figure: ſegments of the calyx linear-lanceolate, acute, the length of the corolla: corolla flat, wheel-ſhaped, deeply divided; ſegments egg-ſhaped: valves of the nectary ſcarcely diſcernible. A native of corn-fields in the South of Europe; and a common annual in Engliſh gardens, where, when once introduced, it generally ſows itſelf without farther trouble. 82. C. *hybrida*. Linn. Sp. Pl. 32. Willd. 71. Mart. 47. Lam. Enc. 62. Ill. 2571. Eng. Bot. 375. "Stem often branched at the baſe, ſtiff, leaves oblong, ſcolloped, waved; corolla ſhorter than the calyx." *Root* annual, ſmall, fibrous. *Stem* nearly erect, a little zigzag, angular. *Leaves* alternate, remote, ſeſſile, rough at the edge. *Flowers* ſmall, terminal, ſolitary, ſeſſile, pale purple: ſtyle and ſtigma club-ſhaped, hairy. From a compariſon of many wild and cultivated ſpecimens of C. ſpeculum and hybrida, Dr. Smith is perſuaded that they are varieties of each other, and that the ſegments of the calyx in both are very variable in length and breadth, as is alſo the corolla in ſize. Linnæus ſuppoſed it a mule produced from C. ſpeculum, impregnated by ſome other plant. A native of corn fields on a chalky ſoil in Cambridgeſhire, Norfolk, and Suffolk, and in ſeveral parts of the Continent of Europe. 83. C. *Pentagonia*. Linn. Sp. Pl. 34. Willd. 75. Mart. 49. Lam. Enc. 64. Ill. 2572. (C. thracica. Tourn. Inſt. p. 112. Rai Hiſt. p. 742. n. 2.) "Stem ſubdivided, much branched: leaves linear acuminate." *Root* annual, ſimple, white. *Stem* ſlender, weak. *Leaves* ſeſſile; lower ones broader. *Flowers* terminal, of a paler blue, twice as large, more concave, and more bell-ſhaped than thoſe of C. ſpeculum, with a corolla leſs deeply divided. Cultivated by Mr. Ray before 1686, from ſeed collected in Thrace, by Mr. Covill of Cambridge. La Marck from the inſpection of ſpecimens preſerved in the herbarium of Juſſieu, judges it to be only a variety of C. hybrida. 84. C. *perfoliata*. Linn. Sp. Pl. 35. Willd. 76. Mart. 50. Lam. Enc. 65. Ill. 2573. Moriſ. hiſt. 2. tab. 2. fig. 3. Barr. rar. 83. tab. 33. Tourn. 112. Rai. hiſ. 743. 3. "Stem ſimple: leaves heart-ſhaped, toothed, embracing the ſtem: flowers ſeſſile, aggregate." *Root* annual. *Stem* from ſix inches to a foot and half high, ſometimes with one or two branches near the bottom, upright, angular, ſlightly woolly. *Flowers* blue, ſmall, axillary, three or four together. A native of Virginia. 85. C. *ericoides*. Lam. Ill. 2574. (C. ſubulata, Thun. Prod. 38? Polemonium roelloides, Linn. jun. Supp. 139?) "Stem erect, ſlender, leaves awl-ſhaped, tooth-ciliated: panicle naked, few-flowered. 86. C. *Priſmatocarpus*. Willd. 72. Mart. 75. Hort. Kew. i. p. 224. (C. nitida: Lam. Ill. 275. Priſmatocarpus nitidus: l'Herit. Sert. 2. tab. 3.) "Stems ſhrubby at the baſe: leaves egg-lanceolate, toothed, very ſmooth: flowers terminal; corolla twice the length of the calyx." *Root* annual. *Stem* decumbent. *Flowers* ſeſſile. *Capſule* linear. A native of the Cape of Good Hope; introduced at Kew in 1787. Willdenow intimates a doubt whether it may not be the ſame as C. cernua, n. 76.

* * * Calyx ten-cleft; five alternate ſegments reflexed, covering the capſule.

87. C. *nana*, Lam. Enc. 41. Ill. 2546. "Stem one-flowered: root-leaves inverſely egg-ſhaped, ciliated, rugged: ſtem-leaves lanceolate, a little toothed: calyx hiſpid." Stem two or three inches high. *Stem-leaves* two, alternate, ſlightly hairy. *Flower* large, terminal, upright: border ſometimes a little bearded: ſegments of the calyx lanceolate, ſtraight, expanding. Cultivated in the royal garden at Paris, and ſuppoſed to be a native of the Alps. It differs from C. ceniſia chiefly in its calyx. 88. C. *ligularis*, Lam. Enc. 42. Ill. 2547. "Stem one-flowered: root-leaves ſpatula-ſhaped: ſtem-leaves ſtrap-ſhaped, entire: flower erect." *Stem* three inches high, upright, ſlender, nearly ſmooth. *Stem-leaves* numerous, alternate, ſlightly ciliated. *Flower* terminal, upright, tubular, bell-ſhaped, a little bearded: calyx hiſpid; ſegments almoſt linear. Cultivated in the royal garden at Paris, and ſuppoſed to be a native of the

Alps. 89. C. *barbata*, Linn. Sp. Pl. 22. Willd. 57. Mart. 35. Lam. Enc. 48. Ill. 2548. "Capſules five-celled: ſtem generally few-flowered: leaves lanceolate: corolla bearded." *Root* ſaid by ſome authors to be perennial, by others biennial. *Stem* ſimple, from ſix to eighteen inches high, hairy. *Root leaves* from five to ten, bluntiſh, obſcurely ſcolloped, rather rugged, narrowing into flat petioles. *Stem-leaves* few, ſeſſile. *Flowers* blue or white, peduncled, commonly drooping, few, unilateral: calyx hiſpid: ſmoothiſh on the outſide, bearded within with long white hairs. According to Scopoli, it varies with one, two, three, or four, and ſometimes with a greater number of flowers. According to Haller the capſule is five-angled, but only three-celled. A native of the Alps and other mountains in Europe. 90. C. *alpeſtris*, Mart. 73. Allion. Ped. 2. 418. tab. 6. fig. 3. (C. Allionii, Willd. 54. Vill. delph. 2. tab. 10. C. trilocularis, Turr. fl. ital. Prod. p. 64. n. 10.) "Stem ſimple, generally one flowered, hiſpid: leaves linear-lanceolate, waved, hiſpid." *Root* perennial, creeping. *Stems* numerous, two or three inches high. *Root-leaves* of the firſt year ſmall, blunt, almoſt round; ſucceeding ones longer: bottom ſtem leaves ſtill longer, acute, all roughiſh and ciliated. Haller conſiders it as a variety of the preceding; but Allioni and Villars pronounce it to be diſtinct. A native of the Alps. 91. C. *dichotoma*, Linn. Sp. Pl. 24. Mart. 33. Lam. Enc. 43. Ill. 2549. (C. mollis, β. Willd.) "Capſules five-celled: ſtem forked: flowers drooping." *Root* annual. *Stem* near a foot high, rather ſlender, ſlightly hiſpid; branches ſpreading. *Leaves* ſeſſile, lanceolate-egg-ſhaped, ſcabrous, diſtant, alternate, often oppoſite under the forks of the ſtem. *Flowers* bluiſh, ſolitary, terminal, and in the forks of the branches, on ſhort peduncles: calyx hiſpid; ſegments egg-ſhaped-acuminate. Lam. A native of Sicily and the Levant. 92. C. *mollis*. Linn. Sp. Pl. 25. Willd. 61. Mart. 38. Lam. Ill. 2550. Bot. Mag. 404. (dichotoma β. Enc.) "Capſules five-celled, peduncled: ſtem proſtrate: leaves nearly round." *Stems* decumbent, a little branched, rather ſtiff, hairy. *Leaves* ſmall, ſeſſile, nearly entire, cottony. *Flowers* axillary, ſolitary, on long petioles, ſix times larger than the leaves: calyx large, naked, Linn. A native of Spain and the Levant. 93. C. *Medium*, Linn. Sp. Pl. 21. Willd. 56. Mart. 34. Lam. Enc. 44. Ill. 2551. Coventry or Canterbury bells. "Capſules five-celled; ſtem upright; flowers upright." *Root* biennial. *Stem* two feet high, round, furrowed, hairy, rugged a little branched. *Root-leaves* narrowed at the baſe, into long petioles ſlightly ſcolloped, hairy, harſh to the touch. *Stem-leaves* oblong, ſeſſile, ſcolloped. *Flowers* blue, purple or white, large: ſegments of the corolla ſhallow, reflexed: ſtigma five-cleft. *Capſule* entirely covered by the reflexed ſegments of the calyx. A native of woods on the Continent of Europe; common in Engliſh gardens, where it was cultivated in 1597. 94. C. *punctata*. Willd. 55. Lam. Enc. 45. Ill. 2552. Gmel. Sib. 3. p. 155. tab. 30. "Capſules three-celled; ſtem ſimple, upright: flower nodding." *Stem* about a foot high. *Root-leaves* petioled, egg-ſhaped, acuminate, ſerrated, hairy on both ſides, whitiſh beneath. *Stem-leaves* alternate, lanceolate, attenuated at the baſe into ſhort petioles. *Flowers* at the top of the ſtem, on ſhort peduncles; corolla whitiſh without, hairy within, and marked with purple ſpots. A native of Siberia. 95. C. *pelviformis*, Lam. Enc. 46. Illuſt. 2553. Tourn. Cor. 3. "Capſules five-celled, root-leaves egg-ſhaped, ſerrated, petioled; ſtem-leaves nearly ſeſſile; flower large, baſon-ſhaped." *Root* large, about a foot long, fibrous, whitiſh. *Stems* numerous, ſix or ſeven inches long, generally ſimple, hairy, decumbent. *Leaves* hairy. *Flower* ſolitary, terminal, pale blue; corolla ſhort, a little ſwelling, ſlightly hiſpid at its angles and edges. Found by Tournefort in the iſland of Candia; deſcribed by La Marck, from a dried ſpecimen in the herbarium of Juſſieu, an original drawing by Aubriet and the MSS. of Tournefort. 96. C. *tubuloſa*, Lam. Enc. 47. Ill. 2554. (C. cretica caulibus ſupinis, flore oblongo, Tourn. Cor. 3.) "Root-leaves petioled, egg-ſhaped, unequally toothed, gaſhed at the baſe; ſtem-leaves oblong, ſerrated, ſeſſile; flower oblong." Allied to C. dichotoma. *Stems* numerous, ſlender, procumbent, ſcarcely a foot long, hairy, reddiſh, branched. *Flowers* blue, ſolitary, terminal, upright; calyx half the length of the corolla; corolla tubular. Lam. Found by Tournefort in the iſle of Candia. 97. C. *ſpicata*, Linn. Sp. Pl. 15. Willd. 58. Mart. 36. Lam. Enc. 49. Ill. 2555. "Hiſpid; ſpike looſe, flowers alternate; leaves linear, entire." The whole plant hairy in all its parts. *Root* biennial. *Stem* ſimple, four or five feet high. *Stem-leaves* half embracing the ſtem. *Flowers* blue, ſeſſile, axillary, from one to three in each axil, forming a long ſpike, reſembling that of Viper's bugloſs. A native of the Vallais, Dauphiné, and Alſace. 98. C. *ſpecioſa*, Lam. Ill. 2556. Pourret. chlor. nar. 15. "Hiſpid; leaves linear, tooth-ſcolloped; root-leaves very long; flowers ſomewhat panicled, nodding." A native of the South of France. 99. C. *alpina*, Linn. Sp. Pl. 1659. Willd. 60. Mart. 37. Lam. Enc. 50. Ill. 2557. Jacq. vin. 210. Auſt. 2. tab. 118. Hall. helv. 695. "Stem ſimple; peduncles one-flowered, axillary, with two bractes." *Root* perennial. *Stem* about ſeven inches high, ſmooth. *Root-leaves* linear-oblong, growing wider towards the top, blunt, entire, hairy. *Stem-leaves* ſtrap-ſhaped, ſmaller, ſeſſile. *Flowers* blue, upright; ſtigma trifid. *Capſule* roundiſh, three-celled. *Seeds* browniſh, with a membranous edge. A native of the Alps, and of mountains in Auſtria and Sileſia. 100. C. *ſaxatilis*, Linn. Sp. Pl. 26. Willd. 62. Mart. 39. Lam. Enc. 51. Ill. 2558. (C. cretica ſaxatilis, bellidis fol. Tourn. Inſt. p. 111. Barr. rar. 79. tab. 813. Bocc. muſ. 2. tab. 64.) "Capſules five-keeled; flowers alternate, nodding; leaves inverſely egg-ſhaped, ſcolloped. *Stems* from four inches to a foot high. *Root-leaves* ſpatula-ſhaped, two inches long, ſmooth, rather fleſhy, ſlightly toothed. *Flowers* blue, hairy within. *Capſules* hemiſpherical, five-celled. A native of the iſle of Candia. 101. C. *alliariæfolio*, Willd. 63. (C. orientalis Alliariæfol. Tourn. Cor. 3.) "Root-leaves kidney ſhaped, doubly toothed: ſtem-leaves egg-ſhaped, toothed, ſeſſile." *Root-leaves* large, rather rough, on long petioles; ſtem-leaves ſmall; flowers nodding. A native of the Levant. 102. C. *ſibirica*, Willd. 64. Mart. 40. Lam. Enc. 52. Ill. 2559. Gmel. Sib. 3. tab. 29. Jacq. Auſt. tab. 200. Bot. Mag. 659. "Capſules three-celled; ſtem panicled." *Root* biennial. *Stem* a foot high, upright, angular, ſlightly hiſpid, divided only at the top into a looſe panicle. *Leaves* oblong, almoſt linear, half embracing the ſtem, rough and commonly waved at their edges. *Flowers* ſmall, oblong; capſules hiſpid; peduncles often three-flowered. A native of Siberia, Auſtria, and Piedmont; introduced by Dr. W. Pitcairn in 1783. 103. C. *violæfolia*, Lam. Enc. 53. Ill. 2560. "Capſules covered; root-leaves heart-ſhaped, ſcolloped, petioled; flowers large, peduncled; calyx hiſpid." *Root* ſmall, fibrous. *Stem* three or four inches high. *Root-leaves* a little hairy beneath, and on their petioles, reſembling thoſe of Viola canina. *Stem-leaves* alternate, oblong-oval, toothed on ſhort petioles. *Flowers* two or three; corolla a little bearded: ſegments ſhallow; calyx-ſegments lanceolate. Introduced into the royal garden at Paris in 1765, and ſuppoſed to be a native of Siberia. Lam. in his Illuſtrations expreſſes a doubt, whether it may not be C. carpatica of Jacq. hort. 1. tab. 57. quoted as a ſynonym to our carpatica, n. 33. We have not Jacquin's work at hand, but this plant cannot be the carpatica of the Engliſh gardens figured in the Botanical Magazine, which has a five-cleft calyx, with the ſegments a little reflexed, but not alternate ones, covering the calyx as in all the ſpecies of this diviſion; whereas La Marck deſcribes the calyx of his violæfolia to be, à cinq decoupures lanceolées, et *à ſinus reflechies*, the expreſſion by which he uniformly denotes what we call the five alternate reflexed ſegments. Has he been led into an error by the ambiguous phraſe *calyce reflexo* in the definition of the younger Linnæus? If ſo, the preſent ſpecies muſt be expunged. He appears to have formed his deſcription only from a dried ſpecimen in the herbarium of Juſſieu. 104. C. *heterophylla*, Linn. Sp. Pl. 39. Willd. 84. Mart. 55. Lam. Enc. 54. Ill. 2561. (C. ſaxatilis, foliis inferioribus Bellidis, cæteris Nummulariæ, Tourn. Cor. 3. It. 1. tab. 243.) "Leaves inverſely egg-ſhaped, ſmooth, entire; ſtems ſpreading." *Root* perennial, white, ſweet and full of milk. *Stem* ſlender, feeble, generally ſimple. *Root-leaves* ſpatula-ſhaped, narrowed into petioles, dark green, ſhining. *Stem-leaves* numerous, ſmall, roundiſh, acute, fleſhy, bright green, on ſhort petioles, entire. *Flowers* clear blue, ſmall, axillary and terminal, on ſhort peduncles. A native of the Levant. 105. C. *tridentata*, Linn. Mant. p. 44. Willd. 65. Mart. 41. Lam. Enc. 55. Ill. 2562. Schreb. dec. 3. tab. 2. (C. orientalis pumila; Tourn. Cor. 3.) "Capſule five-celled; ſtem one-flowered; root-leaves three-toothed." *Stem* twice as long as the root-leaves. *Root-leaves* like thoſe of Statice reticulata, lanceolate, wedge-ſhaped, often with three teeth near the ſummit; ſtem-leaves linear. *Flower* large, upright, ſolitary. A native of the Levant. 106. C. *parvifolia*, Lam. Enc. 56. Ill. 2564. (C. orientalis, foliis inciſis, Tourn. Cor. 4.) "Stem branched near the top; root-leaves inverſely egg-ſhaped, ſcolloped, on long petioles. *Stem-leaves* lanceolate-egg-ſhaped, attenuated and gaſhed at the baſe; flowers panicled." *Stem* about a foot high, round, ſlightly pubeſcent. *Flowers* ſmall, numerous, in terminal panicles. A native of the Levant. 107. C. *lyrata*, Lam. Enc. 57. Ill. 2564. (C. foliis profundè [illegible]; fructu duro, Tourn. Cor. 3.) "Hiſpid; root-leaves lyre-ſhaped, on long petioles; terminal lobe heart-ſhaped, ſcolloped; flowers lateral and terminal, nearly ſeſſile." *Stem-leaves* ſeſſile, egg-ſhaped, narrowed at both extremities, gaſhed, toothed. *Flowers* upright. A native of the Levant, confounded by Linnæus with the following. 108. C. *laciniata*, Linn. Sp. 27. Willd. 66. Mart. 42. Lam. Enc. 58. Ill. 2565. (C. græca ſaxatilis, Jacobææ folio. Tourn. Cor. 3. It. 1. p. 99. tab. 99.) The ſynonyms of Linnæus in Species Plantarum taken from C. Bauhin, Moriſon, and Rauwolf, belong to Michauxia campanuloides.) "Capſules peduncled; leaves ſerrated; root-leaves lyre-ſhaped; ſtem-leaves lanceolate." Whole plant ſmooth. *Stem* a foot high, branched. *Flowers* large, terminal and axillary, very open; ſtigma five cleft. A native of Greece. 109. C. *capitata*, Bot. Mag. 811. "Leaves oblong, obtuſe, hiſpid, embracing the ſtem; flowers terminal, cluſtered." Whole plant hiſpid. *Root* biennial. Raiſed by J. Swainſton eſq. at Twickenham, from ſeeds brought from Greece by the late Profeſſor Sibthorp. 110. C. *ſtricta*, Linn. Sp. Pl. 28. Willd. 67. Mart. 43. Lam. Enc. 59. Ill. 2566. (C. orientalis folio longo; Tourn. Cor. 3.) "Leaves hairy; ſtem-leaves lanceolate, ſerrated; ſtem ſimple, flowers ſeſſile." *Stem* a foot and a half high, ſimple, hairy. *Root-leaves* heart or egg-ſhaped, rather oblong, ſerrated, hairy on both ſides, petioled. *Stem-leaves* alternate, remote, ſeſſile, obtuſe, narrowed at the baſe. *Flowers* axillary, ſolitary, upright; calyx hairy. Linn. A native of Syria and Paleſtine. 111. C. *edulis*, Lam. Enc. p. 590. Ill. 2567. Forſk. Ægyp. p. 44. n. 46. "Stem hiſpid, branched; leaves egg-ſhaped, acute, ſerrated, ſeſſile." *Root* thick, eſculent, of an agreeable taſte. *Flowers* pale blue, with violet veins, ſometimes white; ſegments of the calyx ciliated. A native of Arabia. 112. C. *ſtrigoſa*, Willd. 59. Lam. Ill. 2568. Vahl. Symb. 3. p. 34. "Leaves lanceolate, entire; peduncles axillary, one flowered; ſtem beſet with ſtiff briſtles." *Root* annual. *Flowers* nodding; corolla hairy on the outſide. A native of the Levant.

*Propagation and Culture.* Such of the ſpecies as come from the Cape muſt be kept in the dry ſtove, and treated like the other plants of the ſame climate; they may generally be increaſed from cuttings. Moſt of the others are hardy plants, which bear the open air, and will thrive in almoſt any ſituation. Thoſe that are annual are uſually ſown in the ſpring, in the borders of the flower garden; but, if ſown in the preceding autumn, they will be ſtronger and flower a month earlier. The perennial ones are eaſily propagated by parting the roots in autumn, but where this practice is long continued, the plants are apt to degenerate, and at length ſeldom produce ſeeds. It is deſirable, therefore, to raiſe a ſucceſſion from ſeeds, which will produce plants that are more vigorous, and bear a greater profuſion of flowers. The pyramidalis, in particular, is ſeldom fit to adorn halls and chimneys for two ſucceſſive ſeaſons. In order to procure good ſeeds, ſtrong plants ſhould be ſelected which grow in a warm ſituation, and which have been ſcreened from great rains at the time when their flowers were fully open. The ſeeds ſhould be ſown in autumn in pots and boxes filled with light undunged earth; and in the winter ſhould be ſheltered from ſevere froſts under a hotbed frame. In ſummer, they muſt be kept clear from weeds, and moderately watered in very dry ſeaſons. In September, when the leaves of the plants begin to decay, they ſhould be tranſplanted into beds of light ſandy earth without any mixture of dung, and care ſhould be taken not to break or bruiſe the roots. They ſhould be ſet about four inches from each other, and in two years will be ſtrong enough to flower. The Rampion, when it is cultivated for the table, ſhould be ſown in a ſhady border about the latter end of May; and in the courſe of the ſummer ſhould undergo three hoeings to cut up the weeds, and thin the plants to the diſtance of three or four inches. The roots are fit for uſe in the winter, and will continue good till April. If the ſeeds are ſown too early, the plants are apt to flower the ſame ſeaſon, by which the roots are always ſpoiled. See Martyn's Miller.

CAMPANULA *canarienſis*, (Linn. Sp. Pl. 29.) See CANARINA *Campanula*.

CAMPANULA *africana fruteſcens*, (Comm. hort. 2. p. 77. tab. 30.) See ROELLA *ciliata*.

CAMPANULA *capitis bonæ ſpei foliis articulatis*, (Pet. muſ. 21. fig. 157.) See ROELLA *reticulata*.

CAMPANULA *ſphærocephalus*, (Pluk. alm. 77. tab. 152. fig. 6.) See PHYTEUMA *comoſa*.

CAMPANULA *lutea linifolia*, (Lob. ic. 414.) See LINUM *campanulatum*.

CAMPANULA *minor fruteſcens*, (Brown. Jam. 166. tab. 14. fig. 1.) See HAMELIA *chryſantha*.

CAMPANULA *arboreſcens*, (Brown. Jam. 166.) See HAMELIA *grandiflora*.

CAMPANULA *ſerpillifolia*, (C. and J. Bauh. Scheuch. Tourn. Moriſ. Ray.) See LINNÆA.

CAMPANULA, in *Zoology*, a ſpecies of MEDUSA, found in the Greenland ſeas, and deſcribed by O. Fabricius. The diſk is gibbous; border wide, and ciliated; beneath a hairy croſs.

This kind preys on the marine oniſci, crabs, and other ſmall creatures, and is chiefly obſerved in autumn. Its body is of a conic-orbicular form, with the fringe, and hairy croſs of a yellow colour, and ſometimes white; beneath hollow and ſnowy white.

CAMPANULACEÆ, in *Botany*, the fourth order of the ninth claſs of Juſſieu's natural orders, ſo called from their affinity to the genus Campanula. Juſſieu gives them the following character. *Calyx* ſuperior, ſometimes but rarely half inferior; border divided. *Corolla* inſerted on the upper part of the calyx, moſt frequently regular, generally ſhrivelling; border divided. *Stamens* inſerted under the corolla, as many as its ſegments, and generally alternating with them, moſt commonly five; anthers either diſtinct or united. *Germ* glandular above; ſtyle one; ſtigma either ſimple, or divided. *Capſule* moſt commonly five-celled, but in ſome caſes two, five or ſix-celled, often many-ſeeded, and generally opening at its ſides. *Seeds* fixed to the interior angle of the cells. *Stems* generally herbaceous, but ſometimes ſhrubby; milky. *Leaves* moſt frequently alternate. *Flowers* diſtinct, or in a few inſtances aggregate, and encloſed in a common calyx. Juſſieu includes in it, Ceratoſtema, Forgeſia, Mindium, Canarina, Campanula, Trachelium, Roella, Geſneria, Cyphia, Scævola, Phyteuma, Lobelia, and Jaſione. According to Ventenat, its genera are Michauxia, Canarina, Campanula, Trachelium, Roella, Phyteuma, Scævola, Goodenia, Lobelia and Jaſione. His Michauxia is the Mindium of Juſſieu.

CAMPBELL, Archibald, in *Biography*, the deſcendant of an ancient and noble family in Scotland, was born in the year 1598; and having been educated in the profeſſion of the proteſtant religion, according to the ſtricteſt rules of the church of Scotland, as it was ſettled immediately after the reformation, he zealouſly ſupported that church, and the conſtitution of his country, according to the ideas which he had formed of its legal eſtabliſhment. In the earlier period of his life, he avowed his attachment to the king, and was diſtinguiſhed by marks of royal favour. At the commencement, and during the progreſs of the rebellion, he ſeems to have maintained his loyalty; and after the eſtabliſhment of the commonwealth his country was the laſt that ſubmitted, and even then, his ſon did not ſubmit. At length, Argyle himſelf, who had been created marquis in 1641, was induced, by the preſſing circumſtances of the times, and the authoritative interference of general Monk, to yield to the ruling powers. After the reſtoration, he was tried for his compliance, under a charge of treaſon, and ſentenced by the parliament of Scotland to be beheaded. During his trial, he behaved with great firmneſs and dignity: and on the ſcaffold manifeſted the intrepidity of a hero, or rather, as the writer of his life ſays, the conſtancy of a Chriſtian, aſſerting the uprightneſs of his conduct, and the ſincerity of his affection both to king Charles I. and king Charles II. As to his character, Mr. Hume (Hiſt. vol. vi. p. 272.) repreſents him as a man equally ſupple and inflexible, cautious and determined, and entirely qualified to make a figure during a factious and turbulent period. Biog. Brit.

Campbell, Archibald, earl of Argyle, ſon to the former, was educated under his father's eye, in the true principles of loyalty and of the Chriſtian religion, and diſtinguiſhed himſelf, in an eminent degree, by his perſonal character and ſteady attachment to the royal family. When Charles II. was invited home to receive the crown of the kingdom in 1650, he was conſtituted colonel of his majeſty's foot-guards by the Scots parliament, which then aſſerted a kind of ſovereign authority; but he declined accepting the office, till he obtained a commiſſion from the king; to whoſe favour he was recommended by his fidelity and valour in his ſervice, as well as by his affectionate and reſpectful attention to his perſon. After his majeſty's defeat at Worceſter, he adhered inflexibly to the royal cauſe, nor did he deſert it, when the king's affairs were become deſperate, and his own were reduced to a ſimilar condition. After having capitulated in 1655, to the victorious forces of the Engliſh, in conſequence of orders from general Middleton, ſanctioned by the king's authority, he determined to live peaceably, though he would never acknowledge either Oliver's or Richard's government; and of courſe he was obnoxious to perſons in power, and impriſoned by them. After the king's reſtoration, his enemies, jealous of the favour and influence which he was likely to acquire, combined in their attempts to deſtroy him; and they prevailed with the Scots parliament to impriſon him, and to commence a proceſs againſt him for the crime, ſtiled in their laws, leaſing-making, or creating diſſenſion between the king and his ſubjects, by giving the former falſe informations. They proceeded ſo far as to condemn him to loſe his head, and to forfeit his whole eſtate; but the king interpoſed to prevent the final execution of their purpoſes. At length, his friends came into power, and he was releaſed from a long and ſevere impriſonment. He was alſo ſoon after reſtored to his grandfather's title and eſtate, and part of his father's was ordered to be ſold for the payment of his debts. In the ſubſequent part of this reign, he behaved towards his ſovereign with reſpect and affection; and in his oppoſition to thoſe meaſures of the court which he could not approve, he manifeſted a mild and peaceable diſpoſition. When his majeſty thought fit to ſend his brother, the duke of York, into Scotland, in 1681, a parliament was convened, which, among other laws that were propoſed and enacted, paſſed an act for eſtabliſhing a teſt, obliging all who poſſeſſed offices, civil, military, or eccleſiaſtical, to take an oath not to attempt any change in the conſtitution of church or ſtate. This oath contained ſeveral clauſes, aſſerting the king's ſupremacy, renouncing the covenant, and ſanctioning paſſive obedience, introduced by the courtiers, to which the country party added another clauſe, of adhering to the proteſtant religion. The courtiers, however, propoſed, that all princes of the blood ſhould be exempted from the obligation of taking this oath. Argyle zealouſly oppoſed this exception, intimating, that the ſole danger to be dreaded, with regard to the proteſtant religion, muſt proceed from the perverſion of the royal family. His conduct, on this occaſion, excited the indignation of the duke, and expoſed him to its fatal conſequences.

When the earl of Argyle took this teſt, which he was obliged to do as a privy counſellor, he did it with an explanation which he ſubmitted to the approbation of his royal highneſs, and the whole privy-council. The explanation was allowed, and the earl took his ſeat at the board. However, to his great ſurpriſe, he was a few days after committed to priſon, and proſecuted for high treaſon, leaſing-making, and perjury. Three out of five judges found him guilty of the two firſt charges, and a jury of 15 noblemen gave verdict againſt him. The king's leave was obtained for pronouncing ſentence againſt him, but he ordered the execution of it to be delayed. The earl, having little reaſon to expect either juſtice or mercy from his enemies, contrived to make his eſcape from priſon, and arrived ſafely in London, where the place of his concealment was known at court, though the king would not ſuffer him to be arreſted. In the mean while, the privy-council of Scotland publicly proclaimed his ſentence at the croſs, and cauſed his coat of arms to be reverſed and torn. As ſoon as a convenient opportunity occurred, the earl went over to Holland, and continued there during the remaining part of that reign. Conceiving, probably, that his attainder had entirely diſſolved the obligations by which he was bound as a Britiſh ſubject, and conſidering the government in Scotland as unſettled, before king James II. had taken the coronation oath, he concerted meaſures with the duke of Monmouth, and paſſed over to Scotland to aſſemble his friends: but diſappointed in his expectations of ſupport, he was taken priſoner, and beheaded at Edinburgh upon his former unjuſt ſentence, June 30, 1685. Under his misfortunes he manifeſted great firmneſs and ſelf-poſſeſſion; he ate his dinner cheerfully on the day of his death, and, according to his uſual cuſtom, ſlept after it for a quarter of an hour or more very ſoundly; at the place of execution he made a ſhort, grave, and religious ſpeech; he cauſed the poſition of the block to be duly adjuſted; and after a ſolemn declaration, that he forgave all his enemies, he ſubmitted to death with extraordinary reſolution and compoſure. Biog. Brit.

**Campbell, Archibald**, firſt duke of Argyle, was the ſon of the preceding, and a very active promoter of the revolution. He accompanied the prince of Orange to England; was admitted into the convention as earl of Argyle, though his father's attainder was not reverſed; and in the Claim of Rights, the ſentence againſt him was declared to be, what it undoubtedly was, "a reproach upon the nation." When it was carried in the Scottiſh convention, that the crown ſhould be eſtabliſhed on the prince and princeſs of Orange, he was ſent from the nobility, together with ſir James Montgomery, and ſir John Dalrymple, from the barons and boroughs, to offer the crown in the name of the convention, to their majeſties, and to tender them the coronation oath. For this and other eminent ſervices, he was admitted a member of the privy-council, and in 1690, made one of the lords of the treaſury. He was afterwards appointed a colonel of the Scots horſe-guards; and, in 1694, one of the extraordinary lords of ſeſſion. He was likewiſe created duke of Argyle, marquis of Kintyre and Lorn, earl of Campbell and Cowell, viſcount of Lockow and Glengla, lord of Inverary, Mull, Morvern, and Ferrey, by letters patent, bearing date the 23d of June, 1701. He ſent over a regiment to Flanders, for king William's ſervice, the officers of which were of his own name and family, who bravely diſtinguiſhed themſelves through the whole courſe of the war. Biog. Brit.

**Campbell, John**, ſecond duke of Argyle, and alſo duke of Greenwich and baron of Chatham, ſon of the preceding, by Elizabeth daughter of ſir Lionel Talmaſh, was born on the 10th of October, 1678, and betimes devoted to a military life. At the age of 17 years, he was appointed by king William to the command of a regiment of foot, with which he ſerved abroad. In 1703 he ſucceeded to the honours and eſtates of his father; and in 1705 he was nominated lord high commiſſioner to the parliament of Scotland. In 1706 he made a campaign under the duke of Marlborough, and diſtinguiſhed himſelf by his courage and conduct on ſeveral occaſions. On his return to Scotland, he promoted the meaſure of the Union, and incurred ſome degree of unpopularity among his countrymen. In the years 1708 and 1709, he performed ſeveral important ſervices in his military capacity on the continent; in recompence of which he was, in 1710, inſtalled a knight of the garter. Having joined the tory-party, he was, in the following year, appointed ambaſſador extraordinary and plenipotentiary to Charles III. king of Spain, and commander in chief of her majeſty's forces in that kingdom. But by illneſs and want of ſufficient ſupport, he was diſabled from attempting any enterpriſe of importance; and, indeed, the peace of Utrecht ſoon after put an end to hoſtilities. In 1712 he was appointed commander in chief of all the land forces in Scotland; but as he oppoſed the meaſures of the miniſtry, by reſiſting the reſumption of the grants of crown-lands, by cenſuring the peace of Utrecht, by remonſtrating againſt the extenſion of the malt-tax to Scotland, and by ſupporting a bill for diſſolving the union, which he had once zealouſly promoted, he was deprived of all his employments under the crown. However, on the acceſſion of George I. in 1714, they were reſtored to him with ſeveral additional offices of honour and ſervice. In the rebellion of 1715, he had the command of the king's troops in Scotland; and at length compelled the rebels to abandon Perth, and the pretender to quit the kingdom. From this time his political conduct was fluctuating and verſatile; being occaſionally in and out of place, ſometimes ſupporting, and ſometimes oppoſing the miniſtry; at one time condemning, and afterwards defending ſtanding armies. In 1718 he was ſo much in favour as to be advanced to the dignity of a duke of Great Britain, by the title of duke of Greenwich. He afterwards, at different periods, occupied the poſts of lord ſteward of his majeſty's houſehold, maſter-general of the ordnance, and field-marſhal of all his majeſty's forces. In 1739 he vigorouſly oppoſed the adminiſtration of ſir Robert Walpole, and was removed from all his places; but regained them in 1741, when that miniſter was diſplaced. Some diſguſt at the political arrangements which then took place, induced him very ſoon to reſign them. A paralytic diſorder with which he had been for ſome years afflicted, terminated his life in September 1743; and he was interred in Weſtminſter Abbey, where a ſplendid monument, executed by Roubiliac, was erected to his memory, ſome years after his deceaſe. The titles of duke and earl of Greenwich, and baron of Chatham, became extinct at his death; but his Scottiſh titles devolved on his brother Archibald, earl of Ila. His memory has been uſually honoured with the title of the *great* duke of Argyle; and he has been celebrated in very high terms both by Pope and Thomſon. The encomium of the latter, in his Autumn, is diffuſe: that of the former is more conciſe:

"Argyle, the ſtate's whole thunder born to wield,
And ſhake alike the ſenate and the field."
Epilogue to the Satires, dial. ii.

His character is leſs favourably ſketched by Mr. Macpherſon in his "Hiſtory of Great Britain, vol. ii. p. 601." Careleſs and eager in his diſpoſition, he neither concealed his reſentment nor diſguiſed his deſigns. With a commanding manner, which ſtamped his very forwardneſs with an appearance of authority, he was feared by many, but beloved by none. Brave in his perſon, but not remarkable for his conduct; he might be conſidered, in his military capacity, as a bold partizan rather than a judicious commander. In his civil character, his fire degenerated into a violence, that often defeated his views. In his public exhibitions in parliament, he was rather ſpirited than eloquent; better calculated to terrify his enemies than to ſupport his friends. His great defect was a love of money and emolument, which he could not effectually conceal, with all the efforts of his pride. His chief talent was an addreſs in managing the prejudices of the vulgar. He marked their opinions as they changed, and fell dexterouſly down with the tide." In private life he is allowed to have been an affectionate huſband, and an indulgent maſter, a liberal friend to the poor, and a generous patron of merit in diſtreſs. As a ſtrict economiſt, he took care to maintain the dignity of his rank, without waſting any part of his income in empty pomp, or unneceſſary expences. Biog. Brit.

**Campbell, Archibald**, third duke of Argyle, was born at Ham-houſe in England, in 1682, and educated at the univerſity of Glaſgow. Although he ſtudied law at Utrecht with a view to the bar, he declined purſuing it, and devoted himſelf to a military life. But he ſoon abandoned the army, and determined on acquiring the neceſſary qualifications for a ſtateſman. Accordingly, he occupied ſeveral poſts of truſt and dignity in Scotland, which we ſhall not here enumerate. As chancellor of the univerſity of Aberdeen, he laboured to promote the intereſt of that, as well as of the other univerſities of Scotland; and he particularly encouraged the ſchool of phyſic at Edinburgh, which has ſince acquired ſuch high reputation. He was a man of great natural and acquired endowments, well verſed in the laws of his country, eminent for his knowledge of human nature, and poſſeſſed of very conſiderable parliamentary abilities. As he had the chief management of Scots affairs, he was very attentive to promote the trade and manufactures of Scotland, and to forward improvements for the good of the country. He excelled in converſation, and collected one of the moſt valuable private libraries in Great Britain. At Inverary he built for himſelf a very magnificent ſeat. Having retained his faculties in full vigour till his 79th year, he died ſuddenly in April, 1761; and was ſucceeded in his titles and the eſtates of his family by John Campbell, fourth duke of Argyle, ſon of the honourable John Campbell of Mammore, who was the ſecond ſon of Archibald, the ninth earl of Argyle. Biog. Brit.

**Campbell, John**, an ingenious writer, was the fourth ſon of Robert Campbell of Glenlyon, Eſq., and was born at Edinburgh in 1708. At the early age of five years, he was brought by his mother to Windſor, where her father reſided, and at a ſuitable age articled to an attorney. But the ſtudy of the law not ſuiting his taſte, he devoted himſelf to a literary life, and in due time engaged in the profeſſion of an author, in which he acquired eminence. His earlieſt productions are not now known; but in 1736, he publiſhed in 2 volumes folio, "The military Hiſtory of Prince Eugene and the Duke of Marlborough, &c." The reputation which he acquired by this performance, occaſioned his being employed in the compilation of the "Ancient Univerſal Hiſtory," in which he wrote, beſides other parts that are not poſitively aſcertained, the Coſmogony. The firſt work to which he prefixed his name, was "The Lives of the Engliſh Admirals, and other eminent Britiſh Seamen," of which 2 volumes were publiſhed in 1742; and the two remaining volumes were completed in 1744. This work was ſo well received, that it paſſed through three editions in the author's own life-time, and a fourth has been ſince reprinted under the inſpection of Dr. Berkenhout. His curious and entertaining pamphlet, entitled "Hermippus Redivivus, or the Sage's Triumph over old Age and the Grave; wherein a Method is laid down for prolonging the Life and Vigour of Man," was publiſhed in 1743. This ſecret is founded upon an ancient inſcription preſerved in Reineſius's ſupplement to Gruter, and conſiſts in inhaling the breath of young females. Campbell's tract had its origin in a foreign publication, which ſuggeſted the idea, improved by our author with additional learning, and in a ſtrain of grave irony, which made it doubtful whether he was in jeſt or earneſt. According to his account, indeed, the true key of the work was an imitation of Bayle's manner of writing on a difficult ſubject, without diſcovering to which ſide his own ſentiments inclined. In 1744, he publiſhed in 2 volumes folio, a much improved edition of "Harris's Collection of Voyages and Travels," which was very favourably received. The next work in which Mr. Campbell engaged, was the "Biographia Britannica," the publication of which commenced in 1745; and his articles are allowed to conſtitute the principal merit of the four volumes through which they extend. With regard to the extent of his reſearch, and the variety of information which he communicates, as well as the correct and animated ſtyle, generally elegant, though ſomewhat too diffuſe, in which he writes, he ſurpaſſes his coadjutors in that comprehenſive and uſeful work. If he errs, it is on the ſide of candour, and a freedom from party-prejudice, which have ſometimes degenerated into a ſyſtem of univerſal panegyric or apology. To the benevolence of his temper, and in ſome caſes to his ſuperior knowledge, and not to any intention of flattering or deceiving, this error ought to be aſcribed. To Mr. Dodſley's "Preceptor," which appeared in 1748, Mr. Campbell contributed the introduction to chronology, and the diſcourſe on trade and commerce. In 1750, he publiſhed the firſt ſeparate edition of his "Preſent State of Europe," which became very popular, and which contains, in a moderate compaſs, a great variety of hiſtorical and political information. The next great undertaking, in which our author's abilities and learning were eminently diſplayed, was "The Modern Univerſal Hiſtory," to which he contributed the hiſtories of the Portugueſe, Dutch, Spaniſh, French, Swediſh, Daniſh, and Oſtend ſettlements in the Eaſt Indies, and the hiſtories of the kingdoms of Spain, Portugal, Algarve, Navarre, and that of France, from Clovis to the year 1656. As our author had thus diſtinguiſhed himſelf in the literary world, the degree of LL. D. was very properly and honourably conferred upon him, in 1754, by the univerſity of Glaſgow. During the intervals of his greater labours, ſeveral ſmaller and anonymous works proceeded from his fertile pen. Among theſe, we may reckon his "Deſcription and Hiſtory of the new Sugar Iſlands in the Weſt Indies," which was written upon the concluſion of the peace of Paris, at the requeſt of lord Bute, as a vindication of that peace. This treatiſe was deſigned to ſhew the value and importance of the neutral iſlands that had been ceded to us by the French. It was preſented to his majeſty with a MS. dedication. It was probably in recompence of his political ſervices, that he was appointed in 1765 his majeſty's agent for the province of Georgia, in North America, which employment he held till his deceaſe.

The laſt and great work of Dr. Campbell, to which he had devoted many years of his life, was his "Political Survey of Britain," which appeared in 2 vols. 4to. in 1774. In this work, the author's patriotiſm and the extent of his knowledge were eminently diſplayed; but though it muſt be allowed to contain numerous plans and hints of improvement, which duly regarded would contribute to preſerve and perpetuate the proſperity of this iſland, ſome of its projects are founded on erroneous principles, others are of queſtionable importance and utility, and the reader, who wiſhes to acquire a juſt knowledge of the ſtate of theſe kingdoms, ſhould conſult it with caution. The diſcuſſions to which it leads engaged the author in a very extenſive correſpondence; and he derived from it a very conſiderable increaſe of reputation. Dr. Campbell's literary character was highly reſpected not only in his own country, but in the remoteſt parts of Europe. To this purpoſe it may be mentioned, that the empreſs of Ruſſia, in 1774, condeſcended to honour him with the preſent of her picture, drawn in the robes worn in that country in the days of John Baſilowitz, grand duke of Muſcovy, who was contemporary with queen Elizabeth. In return, the author conveyed to St. Peterſburg a ſet of the "Political Survey of Britain," bound in morocco, highly ornamented, and accompanied with a letter deſcriptive of the triumphs and felicities of her reign.

As Dr. Campbell's literary engagements allowed of few foreign avocations, his life was ſedentary and domeſtic; but by exerciſe in his garden and houſe, and a courſe of temperance and abſtemiouſneſs, he guarded againſt the inconveniences incident to this kind of life, and enjoyed a good ſtate of health, though his conſtitution was delicate. His general reputation, and his inſtructive, chearful converſation, drew to his houſe, particularly on a Sunday evening, a great number of literary friends and perſons of all ranks and profeſſions, who were deſirous of teſtifying their reſpect for his merit, and of deriving improvement and pleaſure from intercourſe with him. His knowledge was far from being reſtricted to thoſe ſubjects which employed his pen as an author; but he was well acquainted with mathematics and medicine, with the ancient and modern languages, and with the different parts of ſacred literature. His memory was ſingularly retentive; and he had an uncommon facility in communicating his ideas. The ſtyle of his works had been formed upon the model of that of biſhop Sprat, and was perſpicuous, eaſy, flowing, and harmonious. "To all theſe accompliſhments of the underſtanding, he joined the more important virtues of a moral and pious character. His diſpoſition was gentle and humane, and his manners kind and obliging. He was the moſt tender huſband, a moſt indulgent parent, a kind maſter, a firm and ſincere friend. To his great Creator, he paid the conſtant and ardent tribute of devotion, duty, and reverence; and in his correſpondence he ſhowed that a ſenſe of piety was always neareſt his heart." It was our author's cuſtom every day to read one or more portions of ſcripture in the original, with the ancient verſions, and the beſt commentators before him; and in this way, as appears from his own occaſional notes and remarks, he went through the ſacred writings a number of times with great thankfulneſs and advantage. His ſevere ſtudy at length brought on a decline which terminated his life, December 28, 1775, when he had nearly completed the 68th year of his age. Biog. Brit.

CAMPBELL, GEORGE, an eminent metaphyſician, divine, and biblical critic, was the youngeſt ſon of Mr. Colin Campbell, one of the miniſters of Aberdeen, and born in that city, December the 25th, 1719. Although he had the misfortune to loſe his father at an early age, he made a conſiderable proficiency in the Latin and Greek claſſics at the grammar ſchool, and Mariſchal college of his native place. It was his original intention to follow the profeſſion of the law, and with this view he actually ſerved an apprenticeſhip with a writer to the ſignet in Edinburgh. But being ſoon diſguſted with this employment, he directed his attention to the ſtudy of the ſcriptures, and determined to acquire the qualifications that were neceſſary for the office of a clergyman. Accordingly, in 1741, before the term of his apprenticeſhip was fully completed, he attended the divinity lectures of profeſſor Gobdie at Edinburgh; and he afterwards entered himſelf, as a ſtudent of theology, both in King's college, under the care of profeſſor Lumſden, and in Mariſchal college, under the tuition of profeſſor Chalmers. Beſide the advantages which he enjoyed at the univerſity for the proſecution of his theological ſtudies, he belonged to a literary ſociety of 14 learned perſons, which was eſtabliſhed in 1742, and which afforded him additional means and opportunities of improvement.

After completing his ſtudies at the univerſity, and paſſing through the uſual trials before the preſbytery of Aberdeen, Mr. Campbell was licenſed as a probationer, or preacher, in 1746: and two years after he was ordained miniſter of Banchory-Teman, 17 miles W. from Aberdeen. In this ſituation he excelled as a Scripture critic and lecturer; and compoſed a variety of diſcourſes, which were diſtinguiſhed by the ſimplicity and perſpicuity of their ſtyle. Here he formed the plan of his Tranſlation of the four Goſpels, and here he alſo drew up a part of his Philoſophy of Rhetoric. During his ſettlement in this country pariſh, he married a lady, who contributed in a very great degree to the prolongation and happineſs of his life. In June 1757 he was tranſlated to Aberdeen, and became one of the miniſters of that city, where his character as a lecturer was fully eſtabliſhed, and where he delivered a variety of ingenious and learned diſcourſes on rhetoric, criticiſm, and other ſubjects, in a literary ſociety, projected on a larger ſcale than that to which he had formerly belonged, by the late Dr. Reid of Glaſgow, and Dr. Gregory, who were at that time profeſſors of King's College, and eſtabliſhed in 1758. His firſt publication was a ſermon, preached in 1752, at the opening of the ſynod in Aberdeen, on the character of a miniſter, as a teacher and pattern; but as he probably thought that the ſtyle of this diſcourſe was too highly ornamented, he did not include it in the number of ſermons, which he collected a few years before his death. In 1759 he was preſented by his majeſty to the office of principal of Mariſchal College, then vacant by the death of principal Pollock. His advancement to this honourable office was partly owing to the intereſt of Archibald duke of Argyle, to whoſe family he was related, and partly to his known character as a man of diſtinguiſhed abilities and literature. Soon after his appointment to this office, he publiſhed his celebrated "Diſſertation on Miracles," in anſwer to Mr. Hume's eſſay on this ſubject, and thus deſervedly gained the reputation of a moſt acute metaphyſician, and a well-bred polemical writer. The ſubſtance of it was delivered in a ſermon before the provincial ſynod of Aberdeen in 1760, and afterwards moulded into the form of a diſſertation. Before it was publiſhed a copy of it was ſent to Dr. Blair of Edinburgh, and communicated to Mr. Hume; and when the author had availed himſelf of the remarks both of his friend and of his opponent, he preſented it to the public in 1763. Mr. Hume, in a letter addreſſed to the author, acknowledged the civil and obliging manner in which he had been treated; and the Diſſertation was ſo well received by the public, that it ſoon paſſed through ſeveral editions, and was tranſlated into the French, Dutch, and German languages. For a particular account of the author's reaſoning in this diſſertation, ſee our article MIRACLES. Some time before the publication of this treatiſe, the author, without any ſolicitation on his own part, received the degree of doctor of divinity from the neighbouring Univerſity of King's College in Old Aberdeen: a title which he was more ambitious to deſerve than to obtain. Dr. Campbell continued for 12 years to diſcharge the offices of principal of Mariſchal College, and of one of the miniſters of Aberdeen; which he did with great honour to himſelf and ſatisfaction to theſe with whom he was connected. During this period he amuſed himſelf with the ſtudy of botany, in which he became a great proficient; and beſide acquiring a conſiderable knowledge of Hebrew, as well as improving his acquaintance with the Greek and Latin, he made himſelf maſter of the French and Italian, ſo as to become a critic in theſe languages. In 1771 he was elected, by the town-council of Aberdeen, profeſſor of divinity in Mariſchal College in the room of Dr. Gerard; and though he reſigned his paſtoral charge as one of the miniſters of Aberdeen, the united offices of principal and profeſſor of

Mariſchal College devolved upon him a variety of duties, which required great application and exertion. As profeſſor of divinity he nearly doubled the number of lectures which the ſtudents had been accuſtomed to receive, and he finiſhed his courſe in four years, ſo that every ſtudent had an opportunity, if he thought proper, of attending the whole of it. His prelections, in the plan or outline of them, were equally ſimple and comprehenſive. They contained, under the theoretical part, every thing that the ſtudent of divinity ſhould know; and, under the practical branch, every thing that he ſhould do, as a reader of ſacred and church hiſtory, a ſcripture critic, a polemic divine, a pulpit orator, a miniſter of a pariſh, and a member of the church courts on the Scotch eſtabliſhment.

Under the firſt head, or *theory*, he included ſacred or church hiſtory, ſacred criticiſm, and polemic divinity. On ſacred or church hiſtory he delivered thoſe prelections, which he afterwards prepared for the preſs, and which were publiſhed after his death by the Rev. George Skene Keith, in 1800, under the title of "Lectures on Eccleſiaſtical Hiſtory," 2 vols. 8vo. On the ſubject of Scripture criticiſm, inſtead of a tedious and uninteresting diſcuſſion of many ſeparate and minute particulars, he laid down general rules or canons, by which the ſtudents themſelves might be critics without depending upon any commentator. Theſe canons were publiſhed in his Tranſlation of the four Goſpels. His general directions with regard to polemic divinity may be ſummed up in the following ſentences, which, being expreſſed in the moſt ſimple and conciſe language, may be ſoon read and eaſily remembered. We ſhall tranſcribe them for the benefit of thoſe readers whom they may more immediately concern. "Begin with ſtudying the Scriptures in the original languages; attend carefully to the diſtinction, that ſhould always be made, between claſſical or pure Greek, and the Greek of the Septuagint and Teſtament, where the words, taken ſeparately, are pure Greek, but where the idiom of the language, and even the acceptation of many of the words, is derived from the Hebrew, the Chaldaic, or the Syriac. Be acquainted with the civil hiſtory, the manners and cuſtoms of ancient times and nations, eſpecially with that of the Jews, where the reading of Joſephus will often be uſeful. But whatever books you read occaſionally, read the Scriptures frequently. Mark the different paſſages which you do not underſtand; read them with patience, not being too anxious to underſtand every thing at the firſt reading over. But perſevere and read the Scriptures in the original, a ſecond and a third time; and, without conſulting any commentator, thoſe difficult paſſages will always become fewer as your knowledge increaſes. Read the Scriptures alſo with modeſty, neither being too full of yourſelf, nor ſuppoſing that human reaſon can always comprehend divine myſteries: and read them always with fervent prayer to God, the ſource of wiſdom and light, that he would aſſiſt and direct you in your reſearches after truth. Do not complain that you want books, when you have the Scriptures themſelves in the original languages. If you have a Hebrew Bible, a Septuagint, and a Greek New Teſtament, you have the moſt neceſſary, and the moſt uſeful, of all books to a Chriſtian divine. Read carefully all the verſions which are given of diſputed paſſages; make much uſe of verſions, and compare them all carefully with the original. Read the Vulgate, though a tranſlation authorized by the Romiſh church, as well as the verſions of individuals, ſuch as Caſtalio, Beza, Junius, and Tremellius; and alſo Houbigant, if you have acceſs to his tranſlation. You cannot be hurt by reading verſions, and comparing them with the original. But put no confidence in commentators. Conſult them ſparingly, never uſe them till the laſt, and then uſe them only as dictionaries. In this view, however, read commentators of all parties; and judge of them more from their freedom of thought, abilities, and erudition, than from conſidering to what party they belong. In comparing the different kinds of commentators with one another, remember, that paraphraſts are the worſt, becauſe they undertake too much or promiſe moſt; while ſcholiaſts are the beſt, becauſe they undertake and promiſe leaſt. Be on your guard againſt too much ingenuity in commentators: for genius, in this caſe, has often led them aſtray, where humble piety, and plain common ſenſe, would have kept them in the right path. Beware particularly of any attachment to a pre-conceived ſyſtem; and do not think, that you will be ſafe, if you uſe what you call an approved commentator. (It is a pity, though there were leſs danger of being miſled, that a young man of taſte, learning, and genius, ſhould be chained to the opinions, or kept in the trammels, of a commentator.) See always with your own eyes, and not through the ſpectacles of gloſſariſts, commentators, or paraphraſts. Remember that your errors will be much more pardonable, when you uſe your own eyes, and when you come ſhort of the truth, after making the beſt uſe of your own reaſon, than when ye are led implicitly by paſſion, or by prejudice. Let your religious ſyſtem be the laſt thing that ye make; or where ye have made one in early life, be ſtill correcting it, as you acquire more knowledge—not contending for the opinions of men, but enquiring after the mind of the Spirit."

Under the ſecond general head, viz. *Practice*, or the practical part of theology, Dr. Campbell delivered ſeveral excellent prelections to the ſtudents, comprehending pulpit eloquence (See Eloquence), propriety of character in private life, or teaching by example, and propriety of character in public conduct. His manner of delivering theſe lectures was ſuch as to captivate and fix the attention of his ſtudents. His deep and extenſive erudition was irradiated by his fine imagination; and thoſe prelections, which were the moſt abſtracted and learned, were rendered entertaining by ſtrokes of wit and humour which Dr. Campbell took occaſion to introduce. Beſides, he recommended himſelf to the ſtudents, not only by the juſtneſs of his criticiſm, and by his lively mode of lecturing, but by the condeſcenſion and amiableneſs of his whole conduct.

Dr. Campbell, in his 72d year, was ſeized with a ſevere illneſs, which threatened his life; but, contrary to his own expectations and thoſe of his friends, he recovered; and though his bodily ſtrength was impaired, he reſumed his former occupations and ſtudies. Some years before his death he made a diſintereſted and unſolicited offer of reſigning his profeſſorſhip of divinity, provided that any one of thoſe gentlemen whom he named, and to whom he applied for their conſent, were choſen to ſucceed him. The offer, however, was not accepted by the patrons of the profeſſorſhip, and he conſented to retain it, leſt an improper perſon ſhould, in his life-time, be choſen as his ſucceſſor. But when application was made to him, and alſo to the town-council of Aberdeen (the patrons of the profeſſorſhip) in favour of Dr. William Laurence Brown, late miniſter of the Engliſh church, and profeſſor of moral philoſophy, of the law of nature, and of eccleſiaſtical hiſtory, in the Univerſity of Utrecht, who had been driven from theſe offices in conſequence of the French invaſion, he inſtantly reſigned, in 1795, his charge of profeſſor of divinity and miniſter of Gray Friars, which were worth 160l. a year; and expreſſed much ſatisfaction in the appointment of his ſucceſſor. Soon after his reſignation of the profeſſorſhip, government, deſirous of teſtifying, in a public manner, the high reſpect ſo juſtly entertained of his abilities and ſervices, offered him, on condition of reſigning the principalſhip of Mariſchal College, a penſion of 300l. a year. Dr. Campbell accepted this token of his majeſty's munificence, and was ſucceeded in the office of principal alſo by Dr. Brown. This penſion, however, he did not long live to enjoy; though he continued writing till within a week of his death; an event, which he expected with great tranquillity and compoſure. On the 31ſt of March, 1796, after ſome previous ſymptoms of uneaſineſs, he was ſtruck with the palſy, which deprived him of ſpeech, and under which he languiſhed for a few days till he died. He had long accuſtomed himſelf to prepare for death; in a former illneſs he had given the teſtimony of a dying man in favour of religion; and, therefore, he was peculiarly happy in not feeling the pangs of diſſolving nature. A funeral ſermon was preached, on occaſion of his death, by Dr. Brown, in which he has given a ſketch of his character as a public teacher, as the head of a public ſeminary of learning, and as a private chriſtian. His character is thus ſummed up in a few ſentences by his biographer, Mr. Keith. "His imagination was lively and fertile—his underſtanding equally acute and vigorous—and his erudition was at once very deep and wonderfully diverſified. His piety was unfeigned—his morals unimpeached—his temper chearful—and his manners gentle and unaſſuming. His love of truth was even more remarkable than the uncommon ſucceſs with which he fought after it. Where intuitive faculties could be of ſervice to any man, he ſaw at once if he ſaw at all. But his deep perſpicacity was not ſatisfied with a ſuperficial view of any thing: his piercing eye darted to the bottom of every ſubject, to which diſcernment could be applied. Where ſtudy and reflection were neceſſary, he could beſtow as much time on patient thinking, as if he had been poſſeſſed of no genius at all, and had acquired only a ſmall ſhare of erudition. And when once he began to examine any ſubject, he was never ſatisfied till he had viewed it in every light in which it could be ſeen. He always ſought for truth in the love of truth, but he could not bear to be ſuſpected of deviating from it; for he neither courted thoſe who might ſupport, nor feared thoſe who did oppoſe him. The tone of his mind was high, and he would not let it down from the elevation of truth and of virtue. Whether engaged in converſation, or employed in ſtudy, he could paſs eaſily from the lighteſt ſubject to the moſt ſerious one. And the reach of his mind was ſo great, as to comprehend a great variety of ſubjects. He could explore the cauſes of that pleaſure, which ariſes in the mind, from dramatic entertaiments, and lay down the rules of Scripture criticiſm. He could illuſtrate the whole theory of evidence, or detect the falſe reaſonings of Mr. Hume. He could explain the ſpirit of the Goſpel, marking the extremes of ſuperſtition and enthuſiaſm; and both as a philoſopher, and a divine, declare the nature, extent, and importance, of the duty of allegiance. While he zealouſly contended for the faith, he could warn the Chriſtian againſt imbibing a perſecuting ſpirit and yet ſhow the influence of religion upon civil ſociety, warning his countrymen againſt infidelity, before they had ſeen its dreadful effects. He could, with manly eloquence, deſcribe the ſucceſs of the fiſhermen of Galilee, while preaching the doctrine of the croſs to prejudiced Jews, learned Greeks, and ambitious Romans; and at the ſame time, with well applied erudition, he could delineate the characters of the pretended ſucceſſors of the apoſtles, and trace the progreſs of the hierarchy through all the dark and middle ages, until the reformation of religion. As the principal of a college, a profeſſor of divinity, or a miniſter of the Goſpel,—as a true patriot, a good man, and a ſincere Chriſtian; *Quando ullum invenies parem?*"

His different publications in chronological order, beſide the Diſſertation on Miracles, and a ſingle Sermon already mentioned, are as follow:—In 1771 he preached before the Synod of Aberdeen his ſermon on the Spirit of the Goſpel, in which he ſtruck at once both at fanaticiſm and ſuperſtition, and at fanatics and ſuperſtitious perſons of all parties and deſcriptions. In 1776 he publiſhed his "Philoſophy of Rhetoric," which eſtabliſhed his reputation, as an excellent grammarian, an accurate and judicious critic, a man of fine imagination and delicate taſte, and a philoſopher of great acuteneſs and deep penetration. The two firſt chapters of this book had been compoſed as early as 1750; and a remarkable coincidence had taken place between him and Dr. Beattie, on the ſubjects of wit, humour, and ridicule. In 1776 he preached a ſermon on the National Faſt, occaſioned by the American war, in which he diſcuſſes the nature, extent, and importance of the duty of allegiance, and which was very popular. Six thouſand copies of it were afterwards publiſhed at the deſire of dean Tucker, and circulated through America. Although in this ſermon he maintains, that the Britiſh colonies in America had no right, either from reaſon or from Scripture, to throw off their allegiance, he inſinuates that America ſhould be allowed to be independent rather than that Great Britain ſhould continue the war. In 1777 Dr. Campbell publiſhed a ſermon on the ſucceſs of the firſt publiſhers of the Goſpel conſidered as a proof its truth, before the ſociety for propagating Chriſtian knowledge, in which he ſtates this argument for the truth of Chriſtianity in a very forcible manner. In 1779 he publiſhed an addreſs to the people of Scotland, on the alarms which had been raiſed by the bill in favour of the Roman Catholics; in which addreſs he conſiders the doctrine of the Goſpel with regard to perſecution; the concluſions to which found policy would lead us in the toleration of the papiſts; and the proper and Chriſtian expedients for promoting religious knowledge, and repreſſing error. This addreſs exhibits a ſtriking evidence of the liberality of the author's mind, with reſpect to thoſe who differed from him in opinion, and of his diſlike of every ſpecies of intolerance and perſecution. In the ſame year he publiſhed a ſermon on the happy influence of religion on civil ſociety, which was preached at the aſſizes at Aberdeen. In this valuable diſcourſe the preacher has ſhewn, in the moſt ſatisfactory manner, that "religion is highly conducive to the exaltation and felicity of the body politic, or nation, by the tendency and extent of its laws, by the aſſiſtance which it gives to the civil powers, both in ſecuring fidelity and in diſcovering truth; by the nature and importance of its ſanctions; by the poſitive enforcement of equity and good government on the rulers, and of obedience and ſubmiſſion in the people." The laſt work which Dr. Campbell lived to publiſh, was his "Tranſlation of the Four Goſpels, with preliminary Diſſertations and explanatory Notes," in two 4to. volumes. His poſthumous work, entitled "Lectures on Eccleſiaſtical Hiſtory," has been already mentioned. See Keith's Account of the Life and Writings of Dr. George Campbell, prefixed to his "Lectures."

**Campbell**, in *Geography*, a county of America, in the ſtate of Virginia, lying E. of Bedford county, on Staunton river. It is 45 miles long and 30 broad; and contains 7685 inhabitants, including 2488 ſlaves.

**Campbell's** *fort*, a fort of America, in the ſtate of Tenneſſee, near the junction of Holſton river with the Tenneſſee; 135 miles from Abingdon, in Waſhington county, Virginia, and 445 W. of Richmond in Virginia.

**Campbell's** *ſalines*, a tract of country in America, in North Holland, in the ſtate of Tenneſſee, diſcovered by captain Charles Campbell, who obtained a patent for it in 1753 from the governor of Virginia. Since the diſcovery of ſalt-water, and the manufacture of ſalt in this diſtrict, it is become very valuable, and many thouſands of people are now ſupplied from it with ſalt of a ſuperior quality, and at a low price. It conſiſts of about 300 acres of ſalt marſh land, in which pits are ſunk for obtaining the ſalt water. The beſt is found at the depth of from 30 to 40 feet; and after paſſing through the rich ſoil or mud, from 6 to 10 feet, you come to a very brittle lime-ſtone rock, with cracks or chaſms, through which the ſalt-water iſſues into the pits, whence it is drawn by buckets and put into the boilers, which are placed in furnaces adjoining the pits. The hills, that ſurround this flat, are covered with fine timber; and a coal-mine has been diſcovered not far from it.

**Campbell**-*town*, is a royal borough in the county of Argyle, Scotland, ſeated on the banks of the lake of Kilkerran, on the eaſtern ſhore of Kintyre, of which it is the preſbytery ſeat. This place was merely a ſmall fiſhing village till 1701, when it was conſtituted a royal borough, and obtained its preſent appellation. Previous to that period it was called Ceann-loch (Loch-head) which it ſtill retains in the provincial language of the country. From the eſtabliſhment of a fiſhery here, and the advantage of a good harbour, this place has greatly increaſed in ſize and conſequence. The harbour is about two miles long by one broad, and aſſumes the form of a creſcent. It is ſurrounded by high hills, and protected at the entrance by an iſland. The anchorage is good, and meaſures from ſix to ten fathoms water. It is appointed the rendezvous of the buſſes employed in the herring-fiſhery, which is the principal trade of the place. Beſide the fiſhery, here is a conſiderable trade in the diſtillation of whiſkey. The pariſh of Campbell-town is about 11 miles by 8, and includes the greateſt portion of the diſtrict called Kintyre. It is narrowed in the middle by the bay of Machyr-haniſh on one ſide, and the loch of Kilkerran, or harbour of Campbell-town, on the other. The ſoil of the pariſh is various, but the arable land is well cultivated and fertile. At the diſtance of three miles are ſome coal-pits, and a canal has lately been finiſhed to communicate with the collieries and the town. A quantity of fuller's earth, or a kind of ſoapy rock, is obtained in this pariſh. In 1791 the population amounted to 8700. This town, with Air, Irvine, Inverary, and Rothſay, unite in ſending one member to the imperial parliament. It lies 176 miles W. by S. from Edinburgh.

**Campbell**-*town*, a large and flouriſhing town of America, in North Carolina, ſeated on a branch of Cape Fear river, 100 miles above Wilmington; the reſort of many inhabitants and travellers, who carry on a continual commerce by waggons, from the back ſettlements, with large trading boats.—Alſo, a village in Dauphin county, Pennſylvania, ſeated near a water of Quitipihilla creek; 13 miles E. of Harriſburgh, and 96 N. W. of Philadelphia.

**CAMPDEN**, or **Campden-Chipping**, anciently *Câmpedene*, is a borough and corporate town of Glouceſterſhire, England, ſituated in a fertile valley, ſurrounded by cultivated hills and hanging woods. Its remote origin may be inferred from the circumſtance of the Saxon kings aſſembling here, in the year 687, to conſult on the mode of carrying on the war with the Britons. The era, however, in which it attained the greateſt importance, was the 14th century, when it became a principal mart for wool, and the reſidence of many opulent merchants, who exported that commodity to Flanders, which was then the ſeat of the manufacture of cloth for the general ſupply of Europe. After the eſtabliſhment of this trade in England, and the more general diffuſion of the wool buſineſs, Campden was gradually deprived of its conſequence; and both the merchandiſe and manufactures of early days are now totally loſt. In a charter granted by James I. in the year 1605, it is ſtated that this town was an ancient vill, and originally incorporated: it is therein ordered, that its government ſhould in future be veſted in two bailiffs, twelve capital, and twelve inferior burgeſſes, a ſteward, &c. By the charter, the bailiffs and ſteward were empowered to hold a court of record every fourth Friday, and to take cognizance of all pleas of treſpaſs, debt, contract, and fraud, within the borough; provided the reſpective actions were for ſums not exceeding 6l. 13s. 4d. The buildings are principally ranged in one ſtreet, nearly a mile in length; about the middle of which are the court and market houſes. The former is an ancient ſtructure; and the latter was erected, by ſir Baptiſt Hickes, in the year 1624. A capacious manſion, yet remaining, of nearly the ſame age as the court-houſe, is ſaid to have been erected as a reſidence for one of the wool-merchants. The church, dedicated to St. James, ſtands on an eaſy eminence above the town, in the hamlet of Berrington, which tradition affirms to have received its name from the tumuli, or barrows raiſed over the bodies of thoſe who were ſlain in a great battle fought here between the Mercians and the Weſt Saxons; whoſe reſpective encampments are ſaid to have been at Willerſey and Meen-hill in this vicinity: a bridge at Berrington now bears the name of Battle-bridge. The church is an elegant ſtructure, and conſiſts of a ſpacious nave, 60 feet high, with an aiſle on each ſide, a chancel, and a tower at the weſt end, 120 feet high, ornamented in a very chaſte ſtyle. At the eaſt end of each aiſle is a chapel; that on the ſouth ſide is the burial place of the families of Hickes and Noel. To the munificence of the wool merchants, in the flouriſhing period above-mentioned, it is probable that this beautiful building owed its erection: ſeveral of them are here interred, with braſs effigies and memorials. Near the church are ſome remains of a very magnificent manſion, erected by ſir Baptiſt Hickes, ſoon after he purchaſed the manor, early in the 17th century. The population of this pariſh, as returned under the late act, was 1213 perſons, who were chiefly employed in manufactures; the number of houſes 255. Various donations have been made, for the uſe of the poor, and other beneficial purpoſes, particularly by ſir Baptiſt Hickes, whoſe "good deedes done to this towne" have found an accurate regiſter in Stow. Campden is 90 miles N.W. from London; and has a weekly market on Wedneſdays. Among the more diſtinguiſhed natives of this town are Dr. Robert Harris, a celebrated preacher in the intereſt of the commonwealth parliament, and Mr. George Ballard, author of "Memoirs of Britiſh Ladies."

The vicinity of Campden was the theatre of the *Coteſwold Games*, which, in the reigns of James I. and his unfortunate ſucceſſor, were greatly celebrated in this part of England. They were inſtituted by a public-ſpirited attorney, named Robert Dover, of Barton-on-the-Heath, in Warwickſhire, and, like the Olympic games of the ancients, conſiſted of moſt kinds of manly exerciſes. The victors were rewarded by prizes diſtributed by the projector, who for many years ſuperintended the games in perſon. Ben Jonſon, Drayton, and other poets of that age, wrote verſes on this feſtivity. Theſe were collected into one volume, and publiſhed under the title of "Annalia Dubrenſia," in 1636. The breaking out of the civil war terminated theſe diverſions; but the remembrance of them is yet preſerved by an annual meeting of young perſons on Dover-hill, an eminence about half a mile from Campden, where the principal games were celebrated.

CAMPEACHY, a town of America, in Old Mexico, or New Spain, ſituate in the province of Yucatan, on the weſt ſhore of a bay of the ſame name in the gulf of Mexico. Its houſes are well built of ſtone; when taken by the Spaniards, it contained 3000 houſes, and had conſiderable monuments of Indian art and induſtry. It has a good dock and fort, with a governor and garriſon, commanding both the town and harbour. It has been often ſtormed and taken, both by the Engliſh and French Buccaneers, viz. in 1659, 1678, and 1685, at which laſt time theſe freebooters plundered the whole country within 15 miles about it, ſet fire to the fort and town, which the governor would not conſent to ranſom, and burnt to the value of 50,000 l. of Campeachy wood, which was a part of their ſhare of the plunder. The port is large but ſhallow; and it uſed to be a ſtated market for log-wood, of which great quantities grew in the neighbourhood, before the Engliſh landed there, and cut it at the iſthmus, which they entered at Trieſte iſland, near the bottom of the bay, 40 leagues S.W. from Campeachy. The chief manufacture is cotton cloth. N. lat. 19° 30′. W. long. 91° 30′.

CAMPEACHY, or CAMPECHE *Wood*, in *Botany*. See HÆMATOXYLUM *Campechianum*.

CAMPEGGI, LORENZO, in *Biography*, an eminent civilian and prelate of the Romiſh church, was born at Milan in 1474; and having been educated to the profeſſion of the civil law, taught it firſt at Padua, and afterwards at Bologna. After the death of his wife, he entered into the eccleſiaſtical ſtate, and in 1510 was made auditor of the Rota at Rome. In 1512 he was advanced to the biſhopric of Feltre by Julius II. and deputed as his nuncio to Milan and into Germany. In 1517 he was created a cardinal by Leo X.; and in 1519 ſent as legate to England to collect the tenths for the war with the Turks; but he only ſucceeded in obtaining the biſhopric of Saliſbury. In 1524 he was appointed biſhop of Bologna, and delegated by Clement VII. to oppoſe the progreſs of Lutheraniſm in Germany. His legation to Henry VIII. of England, with which he was intruſted in 1528, was a very difficult charge, as, in conjunction with Wolſey, he was to pronounce ſentence concerning the king's divorce from his queen Catherine. When Henry could not be prevailed upon to renounce his project, Campeggi tried to perſuade Catherine to conſent to a voluntary ſeparation, that he might thus ſave the honour and authority of the church; but his endeavours were unavailing. In the following year he was recalled to Rome, and commiſſioned to attend as legate at the diet of Augſburg. He died at Rome in 1539; having, as a man of learning, enjoyed the eſteem of Eraſmus and of other eminent ſcholars, and having approved himſelf a faithful ſervant of the church, in times and circumſtances peculiarly critical and embarraſſing. His conſtitution for the reform of the German clergy, and his letters, throwing light on the hiſtory of his time, of which the principal are found in a collection of letters written to Frederic Nauſea, and printed at Baſil in 1550, are the only literary remains of him that are extant.

His brother, *Thomas Campeggi*, who ſucceeded him in the biſhopric of Feltre, was a learned canoniſt, publiſhed ſeveral works relating to the canon law, and died in 1564. Moreri. Tiraboſchi.

CAMPEL TREVE, in *Geography*, a town of France, in the department of the Ille and Villaine, and diſtrict of Redon; 5¼ leagues S.W. of Rennes.

CAMPELLO. See CALLAO.

CAMPEN, a tolerably large and handſome town of the United Provinces, ſeated on the weſt ſide of the river Yſſel, near its mouth, built in 1286, and fortified after the old manner. The moſt remarkable public buildings are the town houſe, and the churches of St. Nicholas and Notre Dame. It was formerly a place of conſiderable trade; but the port is now choked up by ſand; diſtant 15 leagues N.E. from Amſterdam, and 13 N. from Arnheim. N. lat. 52° 38′. E. long. 5° 35′.

CAMPENEAC, a town of France, in the department of Morbihan, and diſtrict of Ploermel; 1½ league from Ploermel.

CAMPER, PETER, in *Biography*, an ingenious and ſkilful anatomiſt, phyſician, and ſurgeon, born at Leyden in 1722, was early placed by his father under the De Moores to learn the art of deſigning and painting, in which he made ſufficient progreſs to enable him to make drawings of ſuch anatomical preparations as he choſe afterwards to have engraved. Quitting the pencil, he entered ſtudent at Leyden, under Boerhaave and the other profeſſors in that univerſity, but applied in a more particular manner to anatomy, which was his favourite ſtudy. In 1746 he took the degree of doctor in philoſophy and medicine, but continued his reſidence in Leyden until the year 1748, when he came to London, to attend the hoſpitals and anatomical lectures in this city; and having diligently employed twelve months in improving himſelf, and in forming connections with the principal anatomiſts here, he went to Paris. During the tour which he made in England, France, and Switzerland, in 1749, he was appointed profeſſor of philoſophy, medicine, and ſurgery at Franeker; and, in 1755, he was tranſlated to the chair of ſurgery and anatomy at the Athenæum of Amſterdam, where he was, in three years afterwards, alſo appointed profeſſor of medicine. Not finding that he enjoyed the quiet at Amſterdam which was ſuited to his habits of life, he quitted it in 1761, but retained the title of honorary profeſſor in that capital. He paſſed two years at his country-houſe in Frieſland, and was then nominated profeſſor of medicine, ſurgery, anatomy, and botany at Groningen. There he lived till June 1773, when he ſettled at Franeker, in order to ſuperintend the education of his ſons. From this period to that of his death, at the Hague in April 1789, he was occupied in the proſecution of his favourite ſtudies, in viſiting various parts of Europe, and in the performance of many public duties, to which he was called by the wiſhes of his countrymen. In 1762 he had been appointed a repreſentative in the aſſembly of the province of Frieſland; but, in 1787, he was nominated one of the council of ſtate, and was therefore obliged to reſide at the Hague. His death, at the age of 67, was occaſioned by a pleuriſy. Though he taught and cultivated every part of ſurgery, yet his attention ſeems to have been more particularly paid to the practice of midwifery, in which he had been inſtructed by profeſſor Trioen, who ſhewed him the uſe of the lever of Roenhuyſen. Of this inſtrument he gave an hiſtorical account to the Royal Academy of Surgery at Paris, which is publiſhed in the fifth volume of their Memoirs, and which procured him the honour of being made one of their foreign aſſociate members in the year 1774. He had before been made honorary member of the Royal Society in London; and was afterwards, in ſucceſſion, appointed fellow of of the Royal Society, and of the College of Phyſicians at Edinburgh, and of the Imperial Academy at Peterſburgh, and of the Royal Academy of Sciences at Paris, to each of which ſocieties he had ſent communications. He appears to have meditated a work of conſiderable magnitude and importance, of which, however, only two parts were publiſhed; viz. “Demonſtrationum Anatomico-Pathologicarum Liber primus, continens brachii humani fabricam et morbos, in folio maximo, cum quatuor figuris,” Amſtel. 1760; and “Liber ſecundus, continens pelvis humanæ fabricam et morbos,” 1762. The plates, which are commended for their accuracy, are from drawings made by the author. A ſmall time before his death he publiſhed in a Dutch journal at Amſterdam “An Account of a Method of performing the Operation of Lithotomy at two different times, by Peter Camper, M.D. &c.” The proceſs was communicated to him, he ſays, by M. Louis, who aſſured the author that ſince he adopted it, he had not loſt a ſingle patient by lithotomy. The operation is performed at twice, that is, on the firſt day the ſurgeon makes the inciſion into the bladder, the patient is then to be put to bed, and the extraction of the ſtone deferred until the ſecond, third, or fourth day. By this delay, the ſtone was at length taken away with greater facility, and with leſs pain to the patient, than when the whole of the buſineſs was completed at once. The method is not, however, new; it had been recommended by Peter Franco, who lived more than two centuries ago, and it has long ſince been laid aſide again, as attended with much greater inconveniences than the advantage expected compenſated. A tranſlation of this paper is publiſhed in the tenth volume of the London Medical Journal for the year 1789.

In 1789 his ſon, M. Adrian Gilles Camper, publiſhed at the Hague, in Latin, “A Diſſertation on the fracture of the Patella and Olecranon,” by his father, 4to. The object of this diſſertation is to inquire into the various circumſtances attending the accidents which are diſtinguiſhed by the general name of fractured patellæ. It is enriched with a large number of caſes, and with quotations from, and references to, the moſt celebrated authors on the ſubject; and it is accompanied with two plates, which do not reflect much honour on the artiſt. The laſt deſcribes the perfect cure of a fractured patella, though the upper and lower parts of the bone remained four inches diſtant from each other. In 1791 his ſon publiſhed at Utrecht in 4to. another work entitled “Verhandeling van Petrus Camper over het natuurlyk Verſhilder Wezenſtrekkan, &c.” i. e. Treatiſe of the late Peter Camper on the natural difference of features in perſons of various countries and ages; and on beauty, as exhibited in ancient ſculpture and engravings. Followed by the deſcription of a method of delineating various ſorts of heads with accuracy. The profeſſed object of this publication is to prove that the principal rules, laid down by the moſt celebrated painters and limners, are very defective; that they enable the ſtudent neither to delineate national characteriſtics in the countenance, nor to imitate the beauties of ancient ſculptors and artiſts. He contends that the obſervations of the abbé Winckelman, concerning *ideal* beauty, are not well founded; and he profeſſes to have diſcovered, in what that ſpecies of beauty really conſiſts. It is in conſequence of the imperfection of rules, he obſerves, that men of eminence have been ſo defective in their portraits of national characters; thus, in the paintings of De Wit, the chief ſignature of a Jew is a long beard; and Guido Reni, C. Marat, Rubens, and others have given no other characteriſtic of Moors than a black complexion. He denies the propriety of making either the oval, as is the moſt common method, or the triangle, as ſome artiſts have propoſed, the foundation of portraits to be taken in profile: and he propoſes more certain principles in their place. Neither the author's principles nor his mode of illuſtrating them, can be well underſtood without the plates that accompany this work. The general doctrine, however, is, that the difference in form and caſt of countenance proceeds from the relation which the cranium is found to bear to the direction of an horizontal and a perpendicular line. Let us ſuppoſe a frame of wood, ſimilar to that of a picture, to be made perfectly ſquare; and that the upper part be graduated into 90 degrees, proceeding from the right to the left. Let the cranium or head be placed in the centre of this frame. Draw an imaginary line from the lower part of the upper lip to the forehead, which the profeſſor terms the *linea facialis*, and obſerve in what degree it interſects the upper part of the frame; and this will give one characteriſtic, and the ſituation of the maxillæ, reſpecting the perpendicular ſide of the frame, another. E. G. the *linea facialis* of the orang will interſect the horizontal line at 58; that of the Negroe at 70; that of the European, at 80 or 90; while, in the Grecian antique, the facial line will project ten degrees beyond the limits of the frame, forming an angle in a different direction. In the ape, the negroe, and the calmuk, the maxillæ project in various proportions beyond a perpendicular line drawn from the lower part of the forehead to the chin; in the European, the maxillæ are on a line with the perpendicular; and in the antique, they recede within it. According to this poſition of the *linea facialis*, are every other part of the head, the poſition of the eyes, of the mouth, ears, &c. regulated. This Camper proves by various examples.

In 1792 the profeſſor's ſon publiſhed at Utrecht, in 4to. a ſequel to the preceding treatiſe, entitled, “Reden voeringen van wylen Petrus Camper, &c.” i. e. Lectures of the late Peter Camper on the manner of delineating the different emotions of the mind in the countenance;—on the ſtriking reſemblance between quadrupeds, fowls, fiſhes, and the human ſpecies;—and on the conſtituent beauty of form. Illuſtrated by plates. The firſt lecture treats of the manner of repreſenting the different emotions of the mind. For this purpoſe the firſt object, he ſays, is to become well acquainted with the form of the cranium;—the ſecond, with the principal muſcles of the face;—and the third, with the nerves which ſet theſe muſcles in motion. E. G. a perſon under the influence of ſorrow and melancholy, ſuffers his head to ſink, as it were, under the weight of the oppreſſion, or he ſupports it with his hand. The muſcles of the neck no longer maintain the equipoiſe; that is, the nerves belonging to the neck are rendered inert by the influence of this paſſion. On the contrary, a perſon under the influence of mirth and of violent laughter, elevates his head; his breaſt is agitated; he holds his ſides with both hands; his legs begin to fail him, and he would roll on the ground, if the fit continued. A man in a rage, beats with his hands, ſtamps with his feet, and his face is violently convulſed. Reſpect impedes ſpeech; an inward trembling takes away the power of motion, the heart beats, and the livelieſt eyes look downward; if ſhame accompanies the emotion, the blood paints the face, neck, and breaſt with crimſon. Thus, in all emotions, particular nerves are affected; and, conſequently, it is the buſineſs of every painter to make himſelf acquainted with theſe, &c. Conformably to this plan, the profeſſor having firſt given to his audience a general idea of the form of the cranium, of the principal muſcles of the face, and traced the courſe of the nerves, proceeded to point out, by various drafts or ſketches, the changes produced in the countenance in the emotions of ſurpriſe, contempt, complacency, laughter, ſorrow, weeping, wrath, and in death. The ſecond lecture treats of the ſimilarity which exiſts between quadrupeds. The profeſſor maintains that in all the larger animals, inhabiting the three elements, there is one part of the body common to all, and very ſimilar in its form; that the great diverſities obſervable in the animal creation, from man down to the finny tribe, proceed from the diverſity which takes place in the appendages to this central part; and that theſe diverſities are according to the nature of the animal, to the element which it is deſtined to inhabit, to the kind of food by which it is nouriſhed, and to the particular manner of obtaining this food. The permanent part is the trunk; that is, the vertebræ of the back and loins, with the ribs. He then illuſtrates this general idea in the horſe, camel, elephant, greyhound, &c. and then deduces the following ſelf-evident concluſion, that the more perfectly an artiſt is acquainted with the nature of animals, and the deſigns of their formation, the better he will ſucceed in delineating them. In the ſequel of this lecture, various rules are laid down, and examples given, by which artiſts may be enabled accurately to delineate the horſe, cow, dog, camel, &c.; or, with a few ſtrokes of the pencil, to convert the one into the other, merely by an attention to theſe rules, and to the deviations which take place in conſequence of the particular nature of the quadruped. In the third lecture the idea is extended to birds and fiſh.

In the year 1803, a collection of Camper's works was publiſhed at Paris, in 3 vols. 8vo. and a folio atlas of plates, under the title of "Oeuvres de Pierre Camper, qui ont pour Objet l'Hiſtoire Naturelle, Phyſiologie, et l'Anatomie Comparé, &c." i. e. The works of Peter Camper, which treat of natural hiſtory, phyſiology, and comparative anatomy. To theſe volumes a general account of his life, by his ſon, is prefixed, of which we have availed ourſelves in the compilation of this article. The firſt volume comprehends a diſſertation on the orang outang, and ſome others of the monkey tribe, a memoir on the double-horned rhinoceros, another on the rein deer, and conjectures relative to ſome petrified bones found in the mountain of St. Pierre, near Maeſtricht, which profeſſor Camper conſiders as the bones of fiſh. In his account of the orang outang, the profeſſor remarks, that immediately below the ſkin and platyſma myoides, two bags made their appearance on each ſide of the windpipe, the right extending over the clavicle, the left being much leſs. Theſe bags were empty, and each of them communicated with the cavity of the larynx, by means of an opening paſſing between the thyroid cartilage and the os hyoides, and terminating at the ſide of the epiglottis. Some ſpecies of monkies had one bag of a ſimilar kind, but the poſſeſſion of two the profeſſor conſiders as peculiar to the orang outang. This organization ſeems to have been known to Galen; but its uſes are unknown, except that theſe cavities can be filled with air, and compreſſed, at the pleaſure of the animal. The profeſſor obſerved a conformation in the throat of the rein-deer, reſembling that noticed above, with regard to ſome kinds of monkies. The ſecond volume is chiefly occupied with an intereſting account of the elephant; and this article is followed by two eſſays, one on the phyſical reaſons which render man ſubject to more diſeaſes than other animals, and on the means of eſtabliſhing health, which can be derived from comparative anatomy; the other on the origin and the colour of the negroes. Their origin is aſcribed to our firſt parents, and their colour to the long continued effects of the climate in which they lived, the food by which they were nouriſhed, and the diſeaſes to which they were ſubject. The third volume contains lectures on an epidemic diſeaſe of horned cattle; a diſſertation on the phyſical education of children; lectures read to the Academy of Painting; an account of the generation of the pipa, or American toad; obſervations on the croaking of male frogs; and an account of the ſtructure of the bones in birds. In his lectures delivered to the Academy of Painting, the author diſcuſſes the ſubject of phyſical beauty, and his general concluſions are the following: viz. That no philoſopher, or artiſt, has ever proved or taught what properly conſtitutes phyſical beauty;—that we have no innate idea of this, as we have of moral beauty; and that it is only by means of ſtudy that we arrive at the knowledge of what is beautiful in the imitative arts;—that phyſical beauty, whether in man and other animals, or in architecture, does not conſiſt in a certain proportion or ſymmetry of parts;—that in giving different forms to men and animals, nature has not aimed at endowing them with a certain degree of beauty, but only at beſtowing upon them what is uſeful in their particular ſphere;—that all which relates to phyſical beauty is founded only on tacit conſent, habit, and authority;—and that the true and only beauty which exiſts, and ſuch as the greateſt maſters have introduced into architecture, painting, and ſculpture, can be referred to nothing more than the care which they have taken that their works ſhould imitate nature as faithfully as poſſible: while they, at the ſame time, avoid the faults which neceſſarily reſult from the imperfection of viſion, and the refraction of light. No particular form, ſays this author, can, abſtractedly conſidered, conſtitute beauty; the real baſis of beauty, according to his reaſoning, conſiſts in the means being adapted to the end; and, excluſively of this, our ideas are influenced by cuſtoms, national prejudices, and implicit confidence in the taſte and opinions of others. This is a ſubject which has been treated with metaphyſical acumen by Burke, Smith, Aliſon, and Sayer. See Beauty.

The eſſay on the ſtructure of the bones of birds, which terminates this work, contains an account of the ſame peculiar conformation which was deſcribed by Mr. John Hunter in the Philoſophical Tranſactions for 1774; but it appears that this curious ſtructure was diſcovered by profeſſor Camper three years before Mr. Hunter's publication of it, and that it was ſoon afterwards made known to many ſcientific men on the continent. The account of the profeſſor's diſcovery was mentioned in a diſſertation read by M. Charnack, at a public meeting of the univerſity of Groningen, Auguſt 25, 1773, but Mr. Hunter's paper was not read to the Royal Society till the February following. See Bird. The atlas accompanying theſe volumes contains a number of well executed plates.

CAMPESTRE, in *Antiquity*, a ſort of cover for the privities, worn by the Roman ſoldiers in their field exerciſes; being girt under the navel, and hanging down to the knees. The name is ſuppoſed to be formed from *campus*, the field or place where the Roman ſoldiers performed their exerciſes.

CAMPESTRIS, in *Entomology*, a ſpecies of Cimex, commonly found in meadows. The colour is yellowiſh, with a ferruginous ſpot on the wing-caſes. Fabricius.

Campestris, a ſpecies of Cicindela, common in moſt countries of Europe. It is of a green colour, with five white dots on the wing-caſes. Linn. &c. Inhabits ſandy fields chiefly. Donov. Brit. Inſ. &c.

Campestris, in *Ornithology*, a ſpecies of Alauda, about ſeven inches long, that inhabits Europe. The tail-feathers are brown, with the lower half, except of the two middle ones, white: chin and breaſt yellowiſh. Linn.

This is called by Briſſon Alauda Campeſtris, and by Ray and Willughby, Alauda minor Campeſtris, Spipolette by Buffon, Brachlerche by Friſch, and *meadow-lark* by Latham.

CAMPHIRE, or Camphor-tree, in *Botany*. See Laurus *camphora*.

CAMPHOR is a white tranſlucent vegetable product, ſomewhat unctuous to the touch, and tenacious between the teeth; it may be crumbled between the fingers without difficulty; it has a peculiar fragrant odour, not unlike that of roſemary, which diffuſes itſelf to a conſiderable diſtance: its flavour is aromatic and bitter, giving at firſt the ſenſation of heat, but afterwards of remarkable cold. Its ſpecific gravity is 0.996, ſo that it juſt floats on the ſurface of water: when expoſed to a moiſt and warm air, it readily volatilizes: by the contact of flame it immediately takes fire, burning with a large white flame, and much ſmoke; if pure it is wholly conſumed, without leaving any reſidue. When heated in a ſpoon, it diſſolves into an oleaginous liquid.

There are two ſpecies of trees from which the camphor of commerce is procured. That with which Europeans are the beſt acquainted, is the laurus camphora, a large foreſt tree, that grows wild in the iſlands of Borneo and Sumatra. Of this tree, the leaves, the fruit, and every other part, when bruiſed, give out a ſtrong odour of camphor, and the wood is much ſought after as a material for cheſts, &c. becauſe its peculiarly aromatic ſmell renders it impenetrable to ants and other deſtructive inſects. The oldeſt trees in general contain the largeſt proportion of camphor, and it is reckoned a good ſign if the natural crevices in the principal branches have for ſome time paſt yielded ſpontaneouſly a quantity of oil of camphor. The camphor itſelf is found in perpendicular veins near the centre of the tree, or concreted in the knots of the wood. The larger pieces are picked out with a ſharp inſtrument, and the ſmaller ones are procured by means of raſps, to which the camphor adheres, mixed with ſmall bits of wood and other impurities. The ſame tree yields alſo the oil of camphor, which appears to be a very fluid kind of reſin, ſtrongly ſmelling of camphor, and from which a conſiderable portion of this latter ſubſtance may be extracted by diſtillation. This oil exudes ſpontaneouſly from the older trees, but is chiefly procured by inciſion, in the following way: a cavity capable of containing about a quart is cut in the trunk, into which a lighted reed is introduced for about ten minutes, this draws the juices towards the cavity; which, in the ſpace of a night, is compleatly filled with oil; the ſame copious flow of juice continues for three nights longer, after which, by a freſh application of heat, a further but leſs plentiful ſupply is obtained.

In Japan are large foreſts of another ſpecies of laurus, which yields camphor, though not in ſuch abundance as that which we have already deſcribed. In this tree the camphor is not contained in concrete maſſes, ſo that in order to procure it diſtillation muſt be had recourſe to. For this purpoſe, the roots and extremities of the branches, being cut into thin chips, are put into a net or upon a wooden framework, and ſuſpended within a kind of alembic, at the bottom of which is a little water: by the application of a boiling heat, the ſteam penetrates the contents of the net, and carries the camphor along with it into the capital, where it is depoſited like ſnow on the rice ſtraw with which the capital is lined.

The Sumatran camphor is much more eſteemed in the Eaſt than the Japaneſe, from which it may readily be diſtinguiſhed by its ſuperior adheſiveneſs, in conſequence of which, it is much leſs volatile than that which has been procured by diſtillation. All the camphor which comes to Europe is the produce of Borneo or Sumatra, and arrives in the form of irregular lumps of a yellowiſh grey colour, which are ſpungy and very light, and when broken diſcover a cryſtalline granular fracture.

The purification of crude camphor is an art that is carefully kept ſecret by thoſe who are in poſſeſſion of it. Venice had formerly the monopoly of this manufacture, afterwards it was ſucceſsfully practiſed in Holland, and at preſent large quantities are refined by ſome of the Engliſh druggiſts. The proceſs is underſtood to be very ſimple, and probably conſiſts merely in mixing the crude camphor with chalk or lime, and ſubliming it in as high a heat as can be ſafely applied. Spirit of wine has been propoſed and employed on a ſmall ſcale for the purification of camphor, but is ineligible, both on account of its expenſiveneſs and its being incapable of ſeparating any reſin with which the camphor may be deſignedly or accidentally mingled. Simple ſublimed camphor differs from the refined camphor of the ſhops in being of a looſe ſpungy granular conſiſtence like ſnow, but it may eaſily be made to aſſume the cloſe and foliated texture of the latter, by ſimple fuſion in cloſed veſſels.

Although the camphor of commerce is obtained only from the laurus camphora and a kindred ſpecies in Japan, yet its exiſtence has been proved in many other ſpecies of lauri. Thus the roots of the cinnamon tree *(laurus cinnamomum)*, of the caſſia, *(laurus caſſia)*, of the ſaſſafras *(laurus ſaſſafras)*, may be made to yield real camphor by diſtillation, though not in ſufficient quantity to balance the expence. The diſtilled water of fennel ſeeds has been found to depoſit cryſtals of camphor by long ſtanding. It has alſo been diſcovered in the freſh roots of galangal, zedoary, and ginger, and in the ſeeds of cardamom and long pepper. It is probably contained in all the eſſential oils, and has actually been procured from thoſe of juniper, ſage, hyſſop, thyme, peppermint, roſemary, and lavender. The depoſition of cryſtalline grains ſimilar to camphor in old eſſential oils had been obſerved by many of the older chemiſts, but no important inveſtigations took place in conſequence of this diſcovery, till Prouſt took the ſubject in hand, and ſhewed, from accurate and large experiments, that camphor may be profitably prepared from the eſſential oils produced in the ſouthern countries of Europe.

This able chemiſt having accidentally obſerved that the eſſential oil of lavender, diſtilled in the province of Murcia in Spain, depoſited a large proportion of camphor, and that the other eſſential oils of this diſtrict were remarkably fragrant, ſelected the eſſential oils of roſemary, marjoram, ſage, and lavender, as the ſubjects of the following experiments. Equal portions of the four oils were placed in ſhallow earthenware veſſels, and expoſed to ſpontaneous evaporation at a temperature not exceeding 57° Fah. and in proportion as the cryſtals of camphor were depoſited, they were taken out and drained, and kept in well-ſtopped vials. By this ſimple proceſs the oil

| of roſemary yielded | 6.25 | *per cent.* of camphor. |
| — marjoram | 10.14 | ———— |
| — ſage - | 21.06 | ———— |
| — lavender - | 25 | ———— |

The oil of lavender appears to be fully ſaturated with camphor, for although when heated it will take up about $\frac{1}{16}$ of its weight more of this ſubſtance, yet it depoſits by cooling a greater quantity even than it was made to diſſolve. When expoſed to ſpontaneous evaporation the filaments of camphor begin to appear in about twelve hours, and continue to be depoſited till almoſt all the oil is evaporated. In the other oils the cryſtals are later in ſhooting, according to their relative proportions of camphor, and when about four-fifths of the oil are evaporated, the reſidue becomes thick, and ceaſes to depoſit any more cryſtals. The camphor produced by each of theſe four experiments, being dried by ſlight preſſure between filtering paper, was in dry almoſt pulverulent cryſtals as brilliant and almoſt as white as ſnow, and ſo little of the peculiar odour of the oil remained, that it was by no means eaſy to aſcertain, from the ſmell alone, from what ſpecies of oil any particular parcel of cryſtals was obtained.

The proportion of camphor procurable from theſe oils depends,

pends, in ſome degree, on the rate at which the evaporation proceeds, the quantity being in an inverſe ratio to the temperature. If oil of lavender is diſtilled from a water-bath in an alembic, at a temperature inferior to boiling water, till one-third is come over, the remaining two-thirds will depoſit flakes of camphor while cooling; theſe being removed, and the diſtillation repeated, a freſh depoſition will take place in the reſidue; and a third diſtillation will yield all the remaining camphor except about $\frac{1}{2}$ *per cent.* This, however, being a much more rapid proceſs than ſpontaneous evaporation, the total produce of camphor from the three diſtillations does not amount to more than 20 *per cent.*, the reſt being held in ſolution by the oil in the receiver. If the *balneum mariæ* is made to boil, the produce of camphor will be conſiderably diminiſhed, and part will ſublime into the capital of the alembic. The camphor from oil of lavender, by either of theſe methods, is not abſolutely pure, for when ſublimed at a gentle temperature, it leaves behind a ſmall portion of browniſh reſin ſtill mixed with camphor. The moſt economical way of refining this camphor is to mix it with half its weight of chalk or lime, or waſhed wood-aſhes, and ſublime it, by which operation it loſes about $\frac{1}{24}$ of its weight. The produce of refined camphor, therefore, by ſpontaneous evaporation of the oil of lavender, amounts to about 24 *per cent.*, and, by diſtillation, is equal to 19 *per cent.*; this latter method is, however, by far the moſt economical, notwithſtanding the additional expence of fuel and apparatus, as it ſaves both time and the oil, which would otherwiſe be entirely loſt.

The production of camphor by the action of muriatic acid on oil of turpentine, is a diſcovery of very late date: it was firſt effected, accidentally, by M. Kind, in preparing the arthritic liquor of Pott; the experiment was then repeated by Trommſdorff with the ſame reſult; and, laſtly, the ſociety of pharmacy at Paris being informed of theſe facts, nominated three of their members to repeat the inveſtigation, and make a report on the ſubject; from which ſources the following facts are derived.

A ſmall quantity of camphor may be obtained from oil of turpentine by ſimple diſtillation, provided the proceſs is carried on ſufficiently ſlowly. Eight ounces of this fluid were diſtilled in a glaſs alembic, at the temperature of about 124° Fah.; four ounces of very highly rectified eſſential oil paſſed into the recipient, and the capital was found lined with ſmall cryſtals of real camphor.

This ſubſtance, however, is procured in much larger proportions by the aſſiſtance of muriatic acid. Four pounds of oil of turpentine were put into a Woulfe's apparatus, and the retort being charged with an equal weight of decrepitated common ſalt, and half as much ſulphuric acid, the whole of the muriatic acid gas that could be obtained by a moderate heat from theſe materials, was tranſmitted into the oil of turpentine, and wholly abſorbed by it. In conſequence of this, the oil became exceedingly hot, and acquired firſt a light lemon-colour, and towards the end of the proceſs, a clear tranſparent brown, a ſmall quantity of a thick oily fluid being gradually diſengaged and ſinking to the bottom. The liquor being allowed to cool for twenty-four hours, was found converted into a thick cryſtalline maſs, from which, when laid on a ſloping ſurface, the brown liquor drained away. Being then wrapped in filtering paper, and ſubjected to moderate preſſure, twenty-four ounces of a perfectly white cryſtalline matter were left behind of a peculiar odour, in ſome degree participating both of oil of turpentine and muriatic acid. The liquor which had drained from the cryſtals was put into a cool cellar, and, in the ſpace of a few days, was found to have depoſited four ounces more of cryſtals, and two ounces additional were obtained by expoſing it to a powerful freezing mixture. Thus four pounds of oil of turpentine yielded thirty ounces of cryſtals, or not far ſhort of half its weight.

The cryſtals thus obtained acquired a dazzling white colour ſimply by waſhing them with water, but ſtill retained a terebinthinate odour; and the waſhings were acidulous to the taſte, having taken up a little muriatic acid, but were alſo highly aromatic. Another portion of cryſtals being waſhed with a weak ſolution of pearlaſh, was found to reſemble common camphor in its odour, that of turpentine having nearly diſappeared. It was thought that ſublimation would be more effectual than waſhing, in purifying this camphor; accordingly, two portions of it were mixed, the one with an equal weight of charcoal, and the other of quicklime, and were heated in glaſs alembics: the capitals ſoon became covered with radiating cryſtals of a brilliant white colour, entirely free from the terebinthinate odour, and reſembling that of camphor, only not quite ſo powerful. In this ſtate it floats on the ſurface of water, and communicates to it a camphoric flavour, is very inflammable, ſoluble in alcohol, and precipitable from it by the action of water. Nitric acid acts upon it in the ſame manner as on Eaſt Indian camphor, but more ſlowly; but it appears to be wholly inſoluble in acetic acid.

The preſence of camphor having been ſhewn in ſuch a variety of ſubſtances, in all of which, when brought to the higheſt degree of purity, it appears to be abſolutely the ſame, that it may be conſidered as one of the ſecondary vegetable principles; hence an inquiry into its chemical properties and compoſition becomes of conſiderable intereſt.

Camphor, on account of its volatility, requires to be kept in well cloſed veſſels; it is not, however, by any means ſo eaſily evaporable as is generally ſuppoſed. According to Kunſemuller, pulverized camphor ſpread thin and expoſed to the air at a temperature not exceeding 52° Fah. does not loſe more than half its weight in 16 weeks; the ratio of volatilization, however, rapidly increaſes with an increaſe of temperature. The moiſture of the air alſo has a conſiderable effect, the loſs of camphor being much greater in a humid atmoſphere than in a dry one. The degree at which camphor melts is fixed by Venturi at 302 Fah. and by dividing a maſs that has been ſlowly cooled in the direction of its laminæ, it appears to cryſtallize in octohedrons.

Water has little or no action on camphor; at a boiling heat it takes up, however, enough to acquire both the odour and flavour of this ſubſtance. By the aſſiſtance of gum-mucilage or ſugar it forms with water a whitiſh emulſion.

Alcohol at the uſual temperature will take up between a ſeventh and an eighth of its weight of camphor, and when boiling it will diſſolve half its weight, the greater part of which is again depoſited by cooling. If equal parts of camphorized alcohol and ſulphuric acid are diſtilled together, the produce is a camphorized ether, and a tenacious black reſinous maſs remains in the retort. Camphor is alſo copiouſly ſoluble in ſulphuric, and probably in all the other ethers. When camphorized alcohol or ether is mixed with water, nearly the whole of the camphor ſeparates in thick curdy flakes, which, when dried, exhibit the camphor unaltered in any of its properties. Oils, both the expreſſed, the eſſential, and the empyreumatic, combine with camphor, as alſo do the reſins and balſams. The hardeſt and dryeſt reſins are converted by it into a ſoft tenacious maſs, remarkably ſoluble in alcohol. The alkalies, whether in their cauſtic or carbonated ſtate, have no action whatever on camphor, nor will they unite even when aſſiſted with oil or ſoap.

Sulphur and camphor will combine together by means of very gentle fuſion; the reſulting maſs is brittle when cold, but ſoft and tenacious when warm. The alkaline ſulphurets will alſo unite by fuſion with camphor, and retain it when diſſolved in water; the addition of an acid to this ſolution throws down the ſulphur and camphor in a ſtate of intimate combination with each other.

When ſet fire to in atmoſpheric air or oxygen gas, camphor burns with a copious white flame and black ſmoak, and is entirely conſumed. A large quantity of carbonic acid and carburetted hydrogen is produced. The ultimate conſtituent parts of camphor appear to be carbon, hydrogen, and oxygen, but in what proportions is not yet aſcertained.

Camphor when diſtilled *per ſe* riſes unaltered; but if mixed with bole in the proportion of four parts of the latter to one of the former, and ſubjected to dry diſtillation, it is converted to a butyraceous conſiſtence; and by a ſecond diſtillation with an equal quantity of freſh bole is entirely reſolved into a fluid colourleſs oil, and a ſmall portion of watery acidulous liquor, ſmelling ſtrong of camphor; the bole at the ſame is reduced to a black ſparkling powder being almoſt entirely deoxygenated. Clay, according to La Grange, produces the ſame effect. This oil of camphor, according to Koſegarten, is nearly colourleſs, has a peculiar odour like that of thyme and roſemary, and bears a cloſe analogy to the eſſential oils. It is ſoluble in alcohol and ſeparable unaltered from its ſolution by agitation with water. It forms ſavonules with the alkalies, and is eaſily volatilizable for the moſt part by a gentle heat. Nitric acid produces no other effect than tinging it of a reddiſh colour, and even a mixture of this acid with the concentrated ſulphuric only deepens the colour of the oil ſtill more, and brings it to a ſomewhat thicker conſiſtence.

Both vinegar and carbonic acid will diſſolve a ſmall proportion of camphor. The muriatic and fluoric acids when in a ſtate of gas take up a conſiderable quantity, but depoſit nearly the whole by the contact of water. Concentrated ſulphuric acid diſſolves camphor largely even in the cold, but by the aſſiſtance of a moderate heat it takes up ſo much as to form a thick homogeneous maſs, of a brown or black colour, and a ſulphureous odour, which when warm is fluid, but coagulates by a moderate heat, and by evaporation is brought to a reſinous conſiſtence. This is ſoluble in alcohol, but is decompoſed by water, the camphor being diſengaged with little or no alteration, and the mixture now no longer exhaling a ſulphureous but a camphoric odour. The action of oxymuriatic acid on camphorized ſulphuric acid is remarkable: if one part of camphor is diſſolved in eight parts of ſulphuric acid, and this mixture is poured in a retort upon four parts of black oxyd of mangeneſe and as much water, the reſult of a ſlow diſtillation of theſe materials will be acetous acid mixed with a ſmall portion of undecompoſed camphor.

Nitric acid, when ſomewhat concentrated, diſſolves camphor in conſiderable quantities at the uſual temperature. The ſolution is of a very dilute yellow colour, and ſeparates by ſtanding into two diſtinct liquids. The lower conſiſts of a mixture of nitric and camphoric acids, the upper fluid is of the conſiſtence of oil, and is called *acid oil of camphor*: it is a combination of camphoric and nitric acid. This oil is ſoluble in alcohol, but is decompoſable with precipitation of the camphor by water or alkalies. The converſion of camphor into a peculiar acid was firſt obſerved by Koſegarten, and was afterwards more fully elucidated by La Grange.

The proceſs of Koſegarten is the following: Put one part of camphor into a retort, with 12 parts of ſtrong nitric acid, and diſtil it ſlowly to dryneſs: a large quantity of carbonic acid and nitrous gas is diſengaged, and the acid in the receiver is covered with a thin ſtratum of acid oil of camphor; a ſmall portion of camphor ſublimes into the upper part of the retort, and the maſs at the bottom of the veſſel is camphor approaching to the ſtate of a vegetable oxyd. It has no longer the peculiar odour of the original ſubſtance, and when laid on a hot coal it evaporates with ſomewhat of a reſinous odour, but without undergoing combuſtion: it is ſoluble in alcohol but not in water. This oxygenated camphor by being twice diſtilled to dryneſs, with ten parts of nitric acid at each proceſs, is converted to a white pulverulent ſalt, ſoluble in hot water, and which has obtained the name of *camphoric acid.*

The method of La Grange differs chiefly in requiring a ſmaller quantity of nitric acid. He takes one part of camphor and four of nitric acid, and diſtils the mixture by a very gentle heat; the acid that paſſes into the receiver being mixed with four parts more of freſh acid, is returned upon the matter in the retort and again diſtilled. This is repeated five ſeveral times with twenty parts of nitric acid in the whole, and the operation is known to be finiſhed when the liquor in the retort cryſtallizes on cooling. The produce of camphoric acid by either of theſe methods does not much exceed one half of the camphor made uſe of.

Camphoric acid, when cryſtallized haſtily, appears as a maſs of white ſilvery filaments; but by ſlow cooling aſſumes the form of parallelipipedal or rhomboidal plates, which effloreſce on expoſure to the air. To the taſte it is ſlightly ſour and bitteriſh. It reddens ſyrup of violets, and tincture of litmus. It diſſolves eaſily in alcohol and in hot water, but requires 200 parts of this latter fluid at the ordinary temperature for its ſolution. When heated it gives out a thick aromatic ſmoak, and is entirely diſſipated; in cloſe veſſels it ſublimes unaltered, if the heat is not too great. The alcoholic ſolution of this ſalt is not decompoſed by water, a circumſtance that diſtinguiſhes it from benzoic acid, to which it bears a conſiderable reſemblance. It is ſoluble in the expreſſed and eſſential oils, and in the mineral acids, and forms a precipitate with the muriat and ſulphat of iron.

Camphoric acid unites with the ſalifiable baſes forming a genus of ſalts, the CAMPHORATS. Of theſe very little is known. The neutral and earthy camphorats, which are the only ones that have as yet been the ſubject of any experiments, are all decompoſable by heat, except the camphorat of ammonia, which ſublimes unaltered. When expoſed to the blow-pipe, the acid burns off with a blue flame. The camphorats are decompoſable with abſtraction of the baſe by the mineral acids, and with abſtraction of the acid by moſt of the metallic, barytic, and calcareous ſalts. The camphorats of lime, barytes, and magneſia, yield their acid to alcohol.

The uſe of camphor in the arts is to aſſiſt the ſolution of the reſins in various menſtrua. It is employed with ſucceſs in cabinets of Natural Hiſtory to prevent the approach of inſects which appear to be ſtupefied and killed by the pungency of its odour. For its medical properties and application ſee the next article.

CAMPHOR, *Medical uſes of, and pharmaceutical preparations.* Camphor has long been conſidered as an article of high importance in the materia medica, and is in daily uſe for a great variety of purpoſes, in which its beneficial operation is unqueſtionable. Yet it is chiefly as an auxiliary that it is reſorted to, and though a valuable medicine, it does not appear quite to deſerve the very high encomiums that have been given to it by many eminent writers.

In a moderate doſe, camphor when taken into the ſtomach, (mixed with ſome vehicle which will allow of its being divided and diſtributed over this organ) increaſes the real heat of the body, though its firſt effect is often a ſenſation of coldneſs. It ſoon produces a ſtrong tendency to perſpiration; but the pulſe is not ſenſibly affected in quickneſs by a doſe capable of producing copious ſweat, and an elevation of ſpirits like the beginning of intoxication. In a febrile irritable ſtate of body, accompanied with ſpaſmodic affections of the muſcles, camphor may be given with ſafety and advantage; and it acts very decidedly as an antiſpaſmodic, and very materially aſſiſts the action of opium. Experience ſhews that the action of camphor is ſudden and very tranſitory, reſembling in this reſpect that of the eſſential oils, only it muſt always be remembered that on account of the extreme ſolubility of this ſubſtance in moſt of the animal fluids, unleſs it be very minutely divided, it will remain long unaltered in the alimentary canal; and thus the ſame effect may in fact be produced by the length of time in which it remains in contact with the organs, as if its operation were highly permanent.

Experiments have been made both on the human body and on other animals with regard to the effects of camphor in exceſſive doſes, which ſhew it to be poſſeſſed of extremely active deleterious powers, and teach ſome caution in the uſe of this remedy. Camphor given internally to ſmall animals, ſuch as birds, cats, dogs, &c. produced ſevere effects in all. The firſt operation appeared to be that of an exceſſive acrid ſtimulus on the ſtomach, producing foaming at the mouth, violent convulſive twitchings over the body, ſometimes with vomitings; acceſſions of fury in dogs and cats; ſymptoms reſembling intoxication; and laſtly, comatoſe ſtupor and death. On opening the body, the ſtomach was found violently inflamed, and the inteſtines dilated with wind and froth. Twenty four grains proved a pretty certain poiſon to cats. The effects of an over doſe of this ſubſtance on the human body were accurately ſhewn by the experiments to this expreſs object, which Dr. Alexander made on himſelf. On taking one ſcruple the pulſe ſoon fell from 68 to 65: two ſcruples more gave a great and at firſt agreeable ſenſe of warmth in the ſtomach, but ſoon followed by exceſſive anxiety and creeping of the fleſh, nauſea, giddineſs, tremors, convulſions, loſs of recollection, and delirium, coma and quickened pulſe. On drinking warm water, much of the camphor came up from the ſtomach three hours after it had been taken, and with very ſpeedy relief, and the whole of the formidable train of ſymptoms brought on by this raſh experiment ſubſided readily and left no permanent inconvenience.

To inſects and very ſmall animals, the effluvium of camphor, even at a common temperature, is obviouſly exceſſively haraſſing, as they quickly avoid it; but if confined in a cloſe veſſel with a piece of camphor, it proves fatal to many ſpecies.

Camphor is a very powerful antiſeptic; and from this and its ſtimulant powers, all the medicinal virtues attributed to it have been uſually derived. Indeed, to the very great antiſeptic power which it poſſeſſes, may be attributed the ſomewhat exaggerated praiſe which it has received as an internal medicine in the cure of typhus, and (ſo called) *putrid* fevers, in the fever attending local gangrene, and ſimilar diſeaſes; for its efficacy in theſe is certainly not comparable to that of other medicines. In the typhoid diſeaſes attended with ſpaſmodic motions of the limbs (at all times a moſt formidable ſymptom) camphor is peculiarly ſerviceable, and much aſſiſts the action of opium. In rheumatic complaints or other diſorders where a copious ſweat is wanted, there are few medicines ſo certain as a mixture of camphor and nitre, about five grains of the former, and from 15 to 20 of the latter, taken at ſhort intervals.

A very common, and generally cordial and grateful drink, (beſides being a good vehicle for other medicines), is the *miſtura camphorata*, or *camphor julep*, made by rubbing one dram of camphor firſt with a little ſpirit of wine to bring it to a powder, then with half an ounce of ſugar, and adding a pint of boiling water. When cold, the water taſtes ſtrongly and pleaſantly of the camphor, though almoſt the whole ſwims at the top unmixed; and ſo little camphor is diſſolved that neither by evaporation nor by any other method can any viſible quantity be extracted from the water. A very elegant preparation of camphor, often of ſingular uſe in ſpaſmodic irritability of the ſtomach, and inceſſant vomiting, is a ſolution of camphor in water ſaturated with carbonic acid. If pulverized camphor is diffuſed in water in a Nooth's machine or any ſimilar contrivance, the water as it takes up carbonic acid diſſolves alſo a very ſmall portion of the camphor, though it is doubtful whether it takes up in this way more than in the common camphor julep.

Almond emulſion with camphor diſſolved in it is a much ſtronger ſolution of this ſubſtance than the former preparations, the almonds much aſſiſting the ſolution of the camphor. One ſcruple of camphor, (rubbed to powder, with a drop or two of alcohol), two drams of almonds, one dram of ſugar and half a pint of water, make the "emulſio camphorata." It is uſed for the ſame intention as the camphor mixture, and it is alſo much employed as a drink in ſtrangury, difficult micturition, the ardor urinæ of gonorrhœa, and other painful affections of the urinary organs. It is ſaid that magneſia much aſſiſts the ſolubility of the camphor in this emulſion, and is beſides often an uſeful addition as a medicine.

Camphor and opium are very frequently joined both in the liquid and ſolid form. The commoneſt liquid preparation of the two is the "tinctura opii camphorata," or "elixir paregoricum," a medicine of undoubted utility in coughs, oppreſſion of breathing, and many other complaints; and perhaps of all others the commoneſt, (and we may add, one of the ſafeſt and the beſt) of the domeſtic medicines. Camphor is thought peculiarly to counteract the heating and unpleaſant effects of opium, and, together, to determine gently to the ſkin, and to allay ſpaſmodic irritation. They may be well combined in the form of pills, but to divide the camphor and increaſe its ſolubility, it ſhould be rubbed down with a drop or two of alcohol, or ſpirit of ammonia. A bolus is, perhaps, a better form, and the ſolubility of camphor in the ſtomach is further increaſed by being triturated with gum arabic.

Camphor is largely employed as an external application, ſometimes as a ſtimulant and antiſeptic conjoined, as where it enters into the compoſition of the fomentations of aromatic herbs uſed in gangrene or ſphacelus; ſometimes as a ſtimulant and ſuppoſed diſcutient to indolent tumors, rigidity of tendons, and the like; ſometimes as a ſimple ſtimulant, as for example, when uſed as a collyrium to chronic complaints of the eyes, &c.

Camphor for external uſe is diſſolved either in oily or in ſpirituous menſtrua. Olive oil diſſolves it largely, eſpecially when pulverized and aſſiſted by a gentle heat. The ſolution is quite limpid, and often greeniſh. It is a very valuable application of itſelf, or when brought into a kind of ſoap by ſpirit of ammonia. Palm oil with camphor, makes a common and very excellent liniment of the ſtimulating and diſcutient kind. It is yellow and of the conſiſtence of butter. Muriated ammonia in very fine powder, rubbed with camphorated palm-oil, makes a moſt active and valuable liniment.

Camphor is often mixed with reſinous ſubſtances in the harder and compound plaſters and unguents. Here the apothecary ſhould be aware of the remarkable power of camphor

phor, in permanently ſoftening moſt reſinous ſubſtances, ſo that the proper conſiſtence of a plaſter will not allow more than a ſmall doſe of this ſubſtance. The ſtrong, diffuſible, and grateful odour of camphor is often of uſe in maſking the unpleaſant ſmell of other applications.

CAMPHORATA, in *Botany*, hirſuta (Bauh. pin.) monſpelienſium (Bauh. hiſt.) See Camphorosma *monſpeliaca*.

Camphorata *glabra*, (Bauh. pin.) See Camphorosma *glabra*.

Camphorata *africana*, umbellata (Comm. hort. 2. p. 79. tab. 40.) See Selago *corymboſa*.

CAMPHORATED, denotes a thing tinctured, or impregnated with camphor.

Spirit of wine camphorated, is a remedy frequently applied externally in caſes of inflammations, &c.

CAMPHOROSMA, in *Botany*, (from camphora and οσμη, *ſmelling of camphor*.) Linn. gen. 164. Schreb. 221. Willd. 257. Lam. Illuſt. 236. Juſſ. p. 84. (Camphorata, Tourn. act. 1705.) Claſs and order, *tetrandria monogynia*. Nat. ord. *Holoraceæ*, Linn. *Atriplices*, Juſſ. *Chenopodeæ*, Vent.

Gen. Ch. *Cal.* perianth pitcher-ſhaped, four or five cleft half way down, compreſſed, permanent; ſegments acute; two oppoſite ones larger than the other, recurved. *Cor.* none. *Stam.* filaments four or five, thread-ſhaped, equal; anthers oval. *Piſt.* germ egg-ſhaped, compreſſed; ſtyle thread-ſhaped, ſemibifid, longer than the calyx; ſtigmas acute. *Peric.* capſule one-celled, covered with the calyx. *Seed* one, oval, compreſſed, ſhining.

Eſſ. Ch. *Calyx* pitcher-ſhaped: two oppoſite ſegments larger. *Corolla* none. *Capſule* one-ſeeded.

Sp. 1. C. *monſpeliaca*, Linn. Sp. Pl. Lam. Ill. Pl. 86. (Camphorata hirſuta, Bauh. pin. 486. Rai hiſ. 210. Tourn. Act. 1705. p. 313. Buxb. Cent. 1. p. 18. tab. 28. fig. 1. Camphorata monſpelienſium, Bauh. hiſt. 3. p. 379. Lob. Adv. 174. and Ic. 403. Selago ſ. Camphorata, Lugd. 1201.) "Leaves linear-awl-ſhaped, hairy; flowers in cloſe axillary cluſters." *Root* perennial. *Stems* about a foot high, ſhrubby, branched; branches numerous, round, long, hairy, whitiſh at their ſummit. *Leaves* alternate or ſcattered, cloſely ſet, ſmall, rather ſtiff. *Flowers* ſmall, green, pubeſcent without, ſometimes five-cleft. The leaves when rubbed between the fingers ſmell ſomething like camphor. The whole plant abounds in a volatile oily ſalt, and is warm and ſtimulating. An infuſion of it in a doſe from half an ounce to an ounce and a half is ſaid to be of ſervice in the aſthma. A native of a ſandy ſoil in Tartary, Spain, and the ſouth of France. 2. C. *acuta*, Linn. Sp. Pl. Pollich. pal. 4. 167. "Leaves awl-ſhaped, rigid, ſmooth." *Root* perennial, ſlender, ſpindle-ſhaped. *Stems* numerous, ſhrubby, decumbent, round, hairy, roughiſh, branched, from two or three inches to a foot in height; branches alternate. *Leaves* alternate, ſeſſile, entire, ciliated at the baſe, ſmall, pubeſcent, ſoft. *Flowers* ſmall, ſeſſile, axillary, growing two together; calyx roundiſh, hairy; ſegments five, ciliated; ſtamens five; longer than the flower; anthers roundiſh, yellow; germ egg-ſhaped, rather acute. Pollich. A native of dry ſandy fields in the Palatinate, Italy, and Tartary. La Marck obſerves that he is unacquainted with this ſpecies, and that as anthyllis altera Italorum, quoted by Linnæus as a ſynonym, appears to him to belong to ſtellera paſſerina, he ſuſpects that the ſame plant has been inſerted twice in the Species Plantarum, under different names. But as ſtellera paſſerina is alſo deſcribed by Pollich, in his hiſtory of plants growing in the Palatinate, the conjecture of La Marck does not ſeem to be well founded. 3. C. *glabra*, Linn. Sp. Pl. Bauh. pin. 486. Dalech. hiſt. 1179. "Leaves ſomewhat three ſided, ſmooth, unarmed." A native of Switzerland. This ſpecies is obſcure. Haller in the firſt edition of his Swiſs plants, keeps it and polycnemum [illegible] ſeparate, both under the name of camphorata; but in the ſecond edition he puts the ſynonym of camph. glabra Bauh. pin. to his polycnemum. Reichard and La Marck complain that they could not find in Haller the ſynonym referred to by Linnæus. 4. C. *paleacea*, Linn. jun. Supp. 128. "Shrubby; branches ſpike-ſhaped, chaffy, hairy." An evergreen ſhrub, ſcarcely a foot high, regularly branched; branches alternate, covered with chaff; hairs, leaves, and flowers imbricated and intermingled, and all ſo ſmall as to be ſcarcely diſcernible by the naked eye. *Chaff* membranous, white. *Leaves* elliptical, ſmooth, ſeſſile. *Calyx* four-leaved. *Petals* four, very ſhort, ciliated, obtuſe. *Stamens* four, ſcarcely longer than the calyx. *Germ* ſuperior. *Style* capillary. *Stigma* ſimple. A native of the Cape of Good Hope. La Marck obſerves in Encyc. that he believes it to belong to a different genus; he has, nevertheleſs, continued it under camphoroſma, in his Illuſtrations; although nothing can be more evident than its inconſiſtence with the generic character. Willdenow juſtly remarks that the flowers of all the ſpecies require a more accurate examination, and that the generic character cannot be conſidered as fixed. 5. C. *Pteranthus*, Linn. Mant. p. 41. Lam. Enc. vol. i. p. 523. Willd. Mart. (Pteranthus dichotomus, Forſk. Ægypt. 36. Lam. Ill. Pl. 764. Juſſ. 404. Vent. vol. iii. 534. Louichea cervina, l'Herit. Stirp. 1. p. 135. tab. 65. Pteranthus echinatus, Deſfontaines flor. atlan. vol. i. p. 145. Poiret. Enc. vol. v. p. 707.) "Much branched; peduncles ſword-ſhaped, dilated; bractes creſted." *Root* annual, fibrous. *Stems* herbaceous, jointed, dichotomous, or trichotomous below, and much branched above; lower branches in whorls, upper ones oppoſite. *Leaves* in whorls, linear, ſmooth, obtuſe, unequal in ſize. *Flowers* in the fork of the ſtem, and at the ſummits of the branches, green, ſmall; peduncles (common receptacle, Vent.) inverſely conical, compreſſed, ſtriated, hollow, trichotomous at their ſummit; pedicels (partial receptacles, Vent.) ſimilar to the peduncles, each bearing ſeven flowers; one fertile in the centre, with three on each ſide, of which two are barren, and that between them fertile; calyx four-cleft; two oppoſite ſegments oblong, concave, terminated by a recurved point; the two others larger, furniſhed on each ſide near the ſummit with a creſt or membranous wing; ſtamens ſhort; filaments awl-ſhaped, a little united at their baſe; ſtyle bifid; ſtigmas ſimple. *Capſule* rather globular, one-celled, one-ſeeded, not opening. A native of Ægypt and of the kingdom of Tunis, where it flowers all the winter and in the beginning of ſpring. The French botaniſts have formed for it a diſtinct genus on account of its capſule, which does not open at the top, as in the other ſpecies. But unwilling to increaſe the number of genera without abſolute neceſſity, eſpecially in ſo lax a genus, we have followed Willdenow and Martyn in keeping it where Linnæus placed it. The deſcription given by the Swediſh naturaliſt is, however, by no means ſatisfactory: in the ſpecific character, he ſeems to have miſtaken the larger ſegments of the calyx for bractes. We have formed our deſcription from thoſe of Juſſieu, Ventenat and Poiret, compared with La Marck's figure.

Camphorosma, (Mor. hiſt. 3. p. 366. tab. ii. fig. ult.) See Dracocephalum *canarienſe*.

CAMPHUYSEN, Dirk Theodore Raphael, in *Biography*, a painter of landſcapes, cattle, and moon-lights, was born at Gorcum, in 1586, and having learned the art of painting from Diederic Govertze, ſoon not only equalled, but far ſurpaſſed his maſter. He ſtudied nature with judgment and diligence; his pencil was remarkably tender and ſoft; his colouring a juſt repreſentation of nature, and very tranſparent; and his perſpective accurate and well contrived. His pictures, as he left off painting at the age of 18 years, are ſcarce, and fetch conſiderable prices. When he relinquiſhed his profeſſion, he became tutor to the ſons of lord Nieuport, and was recompenſed for his diſcharge of the truſt with the office of ſecretary to that nobleman. The deſigns which he executed by drawing with a pen are highly valued. Pilkington.

CAMPI, MICHAEL, and BALTHASAR, two diſtinguiſhed botaniſts of Lucca, flouriſhed in the early part of the 17th century. Well inſtructed in the writings of Dioſcorides, and of the Arabians, they compared the plants deſcribed by them, with thoſe uſed in the ſhops under the ſame name, which in ſome inſtances they found to be erroneous. They alſo in their excurſions over the Alps, diſcovered ſeveral plants not before known. The works publiſhed by them are, "Nuovo Diſcorſo, &c." 1623, 4to. in which they examine ſome of the articles uſed in the compoſition of the Mithridate. "Del Balſamo," Lucca 1639, 4to. "Specilegio Botanico," 1654, 4to. in which they attempt to ſhew, that the cinnamom now uſed, is not the ſame as the plant deſcribed under that name by Dioſcorides. Haller Bib. Bot.

CAMPIAN, EDMUND, a diſtinguiſhed popiſh martyr in the reign of queen Elizabeth, was born at London 1540, and brought up at Chriſt's hoſpital. He was admitted a ſcholar of St. John's college at Oxford, in 1553, and having taken his degree of M. A. in 1564, entered into orders, and became an eloquent Proteſtant preacher. When queen Elizabeth viſited the univerſity in 1566, he delivered an elegant oration and kept an act in her preſence, with great applauſe. In 1568, he went to Ireland, where he became a convert to popery; and upon being diſcovered in making proſelytes, he was apprehended. However, he made his eſcape into England, and from thence into the Low Countries, and entered into the Engliſh college at Douay. At Rome he was admitted into the ſociety of Jeſuits; and having been ſent by the general of the order into Germany, he at length ſettled at Prague, and for ſix years taught rhetoric and philoſophy in the Jeſuits' college. Having eſtabliſhed his reputation for recovering to the church many perſons who had ſeparated from it, he was recalled to Rome, and deputed by Gregory XIII. in 1580, on the dangerous miſſion to England. Here he was zealous in his endeavours by his diſcourſes and writings to make proſelytes; and he procured to be printed at a private preſs, and induſtriouſly circulated at Oxford, a kind of challenge to the clergy, entitled, "Rationes decem oblati certaminis in cauſa fidei, redditæ Academicis Angliæ." After he had for ſome time concealed himſelf, he was at length diſcovered in diſguiſe at the houſe of a gentleman in Berkſhire, and conveyed to the tower in proceſſion, with a paper affixed to his hat, on which was an inſcription, "Edmund Campian, a moſt pernicious Jeſuit." Soon after, he was convicted of a charge of high treaſon, and in December, 1581, he was hanged and quartered at Tyburn. None have queſtioned his abilities, honeſty, and moral character: and it has been alſo allowed, that he was well ſkilled in the learning of his age and profeſſion. Among ſeveral works, written by him, were "An Univerſal Chronology" and a "Narrative of the Divorce of Henry VIII. from his Queen Catharine," both in Latin; and "Various Conferences on Religion held with Proteſtant Divines in the Tower of London." Whilſt he was in Ireland he wrote in 1570, two books of the hiſtory of that kingdom, publiſhed by ſir James Ware, at Dublin, in 1633. Wood's Athen. Oxon. Nicholſon's Hiſtor. Library. Moreri.

CAMPICURSIO, in the *Ancient Military Art*, a march of armed men for ſeveral miles, from and back again to the camp, to inſtruct them in the military pace. This exerciſe was nearly akin to the *decurſio*, from which it only differed, in that the latter was performed by horſemen, the former alſo by foot.

CAMPIDOCTORES, or CAMPIDUCTORES, in the *Roman Army*, were officers who inſtructed the ſoldiery in the diſcipline and exerciſes of war, and the art of handling their weapons to advantage. Theſe are alſo ſometimes called *campigeni* and *armidoctores*.

CAMPIDUCTOR, in *Middle Age Writers*, ſignifies the leader or commander of an army, or party.

CAMPIGLIA, in *Geography*, a town of Italy, in the duchy of Tuſcany; 26 miles S. of Volterra.

CAMPILLO, a town of Spain, in the county of Seville; three leagues W. of Antequera.

CAMPION, FRANÇOIS, in *Biography*, one of the claimants to the invention of *La regle de l'octave*. It is recorded in Walther, that beſides ſeveral uſeful elementary tracts for the Theorbo and Guitar, in 1705, he publiſhed a treatiſe on accompaniment and compoſition, according to the rules of the octaves, a work generally uſeful for tranſpoſition, to all thoſe who ſtudy ſinging and ſtringed (keyed) inſtruments, or even a ſingle baſe part, which it will inform them how to figure.

CAMPION, in *Botany*. See AGROSTEMMA, CUCUBALUS, LYCHNIS, and SILENE.

CAMPION, in *Geography*, a town of Tartary, which was the capital of the kingdom of Tangut, or of the country lying immediately to the N.W. of the Chineſe province of Shenſi, and formerly remarkable for being a place through which the caravans paſſed in the road from Bucharia to China. It is diſtant 60 miles N. from the great wall of China. N. lat. 40° 25′. E. long. 104° 53′.

CAMPIONI, in *Biography*, an agreeable French compoſer of the Italian ſchool, ſtudent in 1770 at Sienna; whence removing to Florence, he was taken into the ſervice of the grand duke, and compoſed a Te Deum for the birth of his imperial highneſs's eldeſt daughter, full of curious canons and other ingenious contrivances, which was performed by a band of 200 voices and inſtruments. But though this compoſition was with propriety written *alla Paleſtrina*, his printed trios were in the modern Italian ſtyle, and in great favour in England, for more than 10 years, during the middle of the laſt century. They were in an eaſy and graceful taſte, and pleaſed univerſally till the ſuperior force and genius of the elder Stamitz and Boccherini, created new wants and expectations.

CAMPISTRON, JOHN GUALBERT, a French dramatic writer, was born at Toulouſe in 1656, and manifeſted an early taſte for poetry. Being diſcouraged from indulging it by his friends, he abruptly left them, and went to Paris, where he put himſelf under the direction of Racine. His firſt compoſitions were two tragedies, entitled "Virginia" and "Arminius," which were followed by two others of ſuperior merit and more permanent reputation and popularity, viz. "Andronicus" and "Alcibiades." He was recommended by Racine to the duke of Vendôme, as a proper perſon for compoſing a new opera for a magnificent feſtival which he was preparing to give to the dauphin. The piece produced on this occaſion was the heroic paſtoral of "Acis and Galatea," which being the means of introducing him to the duke, laid the foundation of his fortune. The duke, engaged by his talents for converſation and conviviality,

ality, took him as a companion in his campaigns, and advanced him to ſeveral offices of honour and emolument. The circumſtance by which he contributed to the advancement of Alberoni, has been mentioned under that article. Campiſtron, tired at length, both of the camp and the court, withdrew to his native city, of which he was appointed, in 1701, “ Capitoul,” or chief magiſtrate, and in the ſame year he was admitted a member of the French academy. In 1710 he married, and paſſed the remainder of his life in the circle of his family and friends. His death was occaſioned by an apoplexy in 1723. Beſides the dramatic pieces already mentioned, he publiſhed ſeveral others, among which are his “ Phocion,” “ Adrian,” “ Tiridates,” “ Phraates,” and “ Jaloux deſabuſé :” and theſe contributed to ſupport the reputation of the French theatre, though in an inferior degree, after it had loſt Corneille and Racine; neither of whom he could rival. His ſtyle, however, was pure, natural, and ſometimes elegant; but his diſtinguiſhing excellence conſiſted in the diſpoſition of his plans, the modelling of his characters, and the knowledge of ſtage-effect. Nine editions of his “ Theatre” were printed at Paris during his life; but the laſt and beſt was publiſhed ſince his death, in 1750, in 3 vols. 12mo. His brother, Louis Campiſtron, was a Jeſuit, and cultivated French poetry. He alſo wrote funeral orations on the death of Louis XIV. and the dauphin. He died in 1733, aged 77. Moreri. Nouv. Dict. Hiſt.

CAMPIPARS. See CHAMPART.

CAMPITÆ, in *Church Hiſtory*, an appellation given to the Donatiſts on account of their aſſembling in the fields for want of churches. For a ſimilar reaſon, they were alſo denominated *Montenſes* and *Rupitani*.

CAMPITELLO, in *Geography*, a town of the iſland of Corſica; 14 miles S. of Baſtia.

CAMPO, a town of Italy, a fief of the empire, in the ſtate of Genoa; 13 miles N.W. of Genoa.

CAMPO *Baſſo*, a city of Naples, and capital of the Moliſe, ſeated in a fertile plain, producing all the neceſſaries of life. The air is ſalubrious, and the inhabitants, eſtimated at about 6000, carry on a conſiderable trade in articles of cutlery.—C. *Foſto*, a town of Naples, in the province of Abruzzo Ultra.—C. *Liatto*, a town of Naples, in the county of Moliſe; 14 miles E. of Moliſe.—C. *Maggiora*, a town of Naples, in the province of Baſilicata; 14 miles S.E. of Acerenza.—Alſo, a town of Italy in the Tortoneſe, belonging to Piedmont.—C. *Marino*, a town of Naples, in the province of Capitanata; 3 miles S.E. of Termoli.—C. *Marone*, a town of Genoa, deriving its name from the quantity of mulberries growing in its vicinity; 11 miles N.N.W. of Genoa.—C. *Mayor*, a fortified town of Portugal, in the province of Alentejo, containing about 5300 inhabitants; 10 miles N.W. of Badajos in Spain. N. lat. 38° 50′. W. long. 7° 24′.—C. *Marto*, a place of Italy, in the duchy of Piacenza, near which Hannibal is ſaid to have defeated the Romans.—C. *St. Pietro*, a town of the ſtate of Venice, in the Paduan; 18 miles N. of Padua.

CAMPOBELLO, a town of Sicily, in the valley of Mazara; 14 miles N.E. of Girgenti.

CAMPO-BELLO, a long and narrow iſland on the eaſt coaſt of Waſhington county, in the diſtrict of Maine, in America, and the north-eaſternmoſt of all the iſlands of the diſtrict. The north end of this iſland lies in about N. lat. 44° 48′. The ſouth end is 5 miles north-weſterly from Grand Manan iſland.

CAMPOCHIARO, a town of Naples, in the county of Moliſe; 11 miles S. of Moliſe.

CAMPOLI, a town of Naples, in the province of Abruzzo Ultra; 3 miles N. of Teramo. N. lat. 42° 38′. E. long. 13° 55′.

CAMPOLONGO, ÆMILIUS, in *Biography*, born at Padua in 1550, and applying early to the ſtudy of medicine, attained ſuch eminence as to be noticed, and employed by the firſt families in the city; and in 1578 to be appointed profeſſor in that ſcience, an office he continued to hold till the time of his death in 1604. The principal of his works are, “ De Variolis, et de Arthritide,” 4to. 1586; taken principally from the works of Galen, in which he was intimately converſant. “ Methodi Medicinales,” conjointly with Alb. Bottono, 8vo. “ Nova cognoſcendi Morbos Methodus,” 1601, 8vo; and after his death, from his papers, “ De Lue Venerea, Libellus,” Patav. 1625, fol.; and “ De Vermibus, de Uxoris Affectibus, et de Morbis cutaneis,” 1636. Aſtruc de Morb. Ven. Haller. Bib. Med.

CAMPOMANESIA, in *Botany*. Boſc Nouveau Dict. Flor. Peruv. Claſs and order, *icoſandria monogynia*. Nat. ord. *Heſperideæ*, Linn. *Myrti*, Juſſ.

Gen. Ch. *Cal.* perianth five-cleft, permanent: ſegments egg-ſhaped. *Cor.* petals five, egg-ſhaped, concave. *Stam.* numerous, inſerted on the calyx. *Piſt.* germ inferior: ſtyle inclined: ſtigma target-ſhaped, umbilicated. *Peric.* berry globular, compreſſed, one-celled, crowned with the calyx. *Seeds* about twelve, kiney-ſhaped, attached to a fleſhy receptacle. A tree found in Peru, of which no farther details are given. Boſc obſerves, that it is an intermediate genus between Myrtus and Piſidium, and that it appears to agree with Decaſpermum, a genus formed by Forſter, for a plant which has ſince been received as a Piſidium. The preſent plant, perhaps, ought to be admitted into the ſame genus. The form of the ſtyle, and the manner in which the ſeeds are attached to the receptacle, ſeem to conſtitute the only difference. To aſcertain what ought to be the preciſe boundaries of a genus, and to determine what particulars, in the ſtructure of the parts of fructification, ſhould be conſidered as ſolid generic diſtinctions, is a problem which has not hitherto been, and probably may not be, reſolved for many ages yet to come.

CAMPORA, in *Geography*, a town of Naples, in the Principato Citra; 15 miles N.W. of Policaſtro.

CAMPRA, ANDREW, in *Biography*, a French muſician, born at Aix, in 1660, ſettled at Paris in 1685, and firſt became known by the compoſition of motets for the churches and private concerts. He afterwards devoted his talents to compoſitions for the opera, and almoſt rivalled the celebrated Lulli. He ſet a number of ballets and ſerious operas, which are ſtill occaſionally performed; and alſo publiſhed various kinds of muſic, which have been held in eſtimation. The king appointed him muſic-maſter of the royal chapel, and gave him a penſion. He died at Verſailles in 1744. Moreri.

CAMPREDON, in *Geography*, a town of Spain, in the province of Catalonia, at the foot of the Pyrenées, taken by the French, who deſtroyed its fortifications in 1691, and again in 1794; 27 miles N.N.W. of Gerona. N. lat. 42° 20′. W. long. 1° 56′.

CAMP-SHEETING, CAMP-*ſhot*, or CAMPSTEAD, in *Inland-Navigation*, denotes a facing of piles and planks in the front of banks or wharfs, to prevent the banks being worn away.

CAMPSIS, in *Botany*, (Loureiro). See INCARVILLEA.

CAMPTON, in *Geography*, a ſmall townſhip of America, in Grafton county, New Hampſhire, ſituate on the eaſt bank of Pemigawaſſet, the north head water of Merrimack river; 67 miles N.W. of Portſmouth. It was incorporated in 1761, and contains 395 inhabitants. N. lat. 43° 51′.

CAMPUGIALI, in *Geography*, a town of the duchy of Tuſcany; 9 miles W.N.W. of Arezzo.

CAMPUS, in *Antiquity*, a field or vacant plain in a city not built on, left vacant either on account of ſhews, combats, exerciſes, or other uſes of the citizens.

Campus *Maii*, in *Ancient Cuſtoms*, an anniverſary aſſembly of our anceſtors, held on May-day; where they confederated together for defence of the kingdom againſt all its enemies.

Campus *Martius*, a large plain field in the ſuburbs of ancient Rome, lying between the Quirinal and Capitoline mounts, and the Tiber; thus called becauſe conſecrated to the god Mars, and ſet apart for military ſports and exerciſes, to which the Roman youth were trained; as the uſe and handling of arms, and all manner of feats of activity. Here the races were run, either with chariots or ſingle horſes; here alſo ſtood the *villa publica*, or palace for the reception of ambaſſadors, who were not permitted to enter the city. Many of the public *comitia* were held in the ſame field, part of which, for that purpoſe, was cantoned out. The place was alſo nobly decorated with ſtatues, arches, columns, porticos, and the like ſtructures.

Campus *Martius* is alſo uſed in a more general ſenſe by *Middle Age Writers*, for any large plain open place near a great city, wherein the inhabitants were trained to the exerciſe of arms. Of ſuch we find mention at Verona, Tries, Dornic, and even Conſtantinople.

Among the French, *campus martius* was an appellation given to the yearly aſſemblies of the people called by the kings, either for enacting new laws, or deliberating on the great affairs of the nation. They were thus denominated, either becauſe uſually held in the month of March, or in imitation of the *campus martius* of the Romans, which was allotted for the like uſe. In aftertimes they were called *campus majus*, and by corruption, *campus madius*, and *magius*, becauſe the time of holding them was altered by Pepin to the month of May. Under the third line of kings, their aſſemblies took the denomination of ſtates-general, *états generaux*.

Campus *Sceleratus*, a place without the walls of ancient Rome, where the veſtals, who had violated their vow of virginity, were buried alive. See Burying *alive*.

CAMPYLUS, in *Botany*. Boſc. Nouv. Dict. Claſs and order, *pentandria monogynia*.

Gen. Ch. *Cal.* perianth tubular, hairy, tubercled: border five-cleft; ſegments unequal. *Cor.* monopetalous, tubular, bilabiate: upper lip awl-ſhaped; lower lip egg-ſhaped. *Stam.* filaments five, unequal. *Piſt.* germ ſuperior: ſtigma five-lobed. *Peric.* capſule nearly globular, five-celled, many-ſeeded.

Eſſ. Ch. Capſule five-celled. Corolla bilabiate. A ſhrub. *Stem* nearly ſimple, climbing. *Leaves* heart-ſhaped, acute, entire, hairy, petioled, ſometimes alternate. *Flowers* reddiſh white, in long, terminal, zig-zag racemes: bractes three-lobed. A native of dry mountains in China.

CAMRUP, in *Geography*, a diſtrict of Aſam, (which ſee) on the ſide of Dacſhincul, ſituate between three high mountains, at the diſtance of four days' journey from Ghergong. It is remarkable for bad water, noxious air, and confined proſpects. It was the part to which the raja baniſhed thoſe of his ſubjects with whom he was angry.

CAMTOOS, a river of ſouthern Africa, on the ſouth coaſt of the colony of the Cape of Good Hope, formed by a collection of waters from the ſame part of the country with thoſe of the Gauritz river (which ſee), but ſomewhat more eaſterly. It falls into a wide bay of the ſame name, in which the only ſecure anchorage is oppoſite to the mouth of a ſmall ſtream called the "Kromme," or crooked river. Though Camtoos river, juſt within the mouth, is a wide baſon, deep enough to float a ſhip of the line, yet the bar of ſand acroſs the mouth is fordable upon the beach at high water, and frequently dry at low water. Barrow's Africa, vol. ii.

CAMUDOLANUM, in *Ancient Geography*. See Camalodunum.

CAMUL, in *Geography*, a town of Tartary, at the extremity of the kingdom of Cialis, and on the borders of that of Tangut. N. lat. 37° 15'. E. long. 98° 5'.

CAMULODUNUM, in *Ancient Geography*. See Camalodunum.

CAMUNIUM, in *Botany*. See Murraya *exotica*.

CAMUNLODUMUM, in *Ancient Geography*, a town of Albion, aſſigned by Ptolemy to the Brigantes, and placed by Horſley at Gretland, near the river Calder, in Yorkſhire; but Camden and Baxter place it near Almondbury, about ſix miles from Halifax, on the ſame river. Roman antiquities have been found at both theſe places, and there are ſtill viſible veſtiges of walls and ramparts. It ſeems to have been the ſame with the Cambodunum of the Itinerary of Antonine in the ſecond rout, between Calcaria or Tadcaſter, and Manucium or Mancheſter.

CAMURI, in *Ichthyology*, one of the ſynonymous names of Diodon Hystrix among old writers.

CAMUS, probably derived from καμπτω, *I bend*, a perſon with a low, flat noſe, hollowed or ſunk in the middle. The Tartars are great admirers of camus beauties. Rubruquis obſerves, that the wife of the great Genghis Kan, a celebrated beauty, had only two holes for a noſe.

Camus, John-Peter, in *Biography*, an eminent French prelate, was born at Paris in 1582, and nominated by Henry IV., on account of his diſtinguiſhed reputation, to the biſhopric of Bellay, before he had attained the canonical age, to which he was conſecrated in 1609, having previouſly obtained a diſpenſation from the pope. His attacks on the Mendicant orders, for their indolence and relaxed diſcipline, both from the pulpit and the preſs, were ſo acrimonious and ſevere, that the monks applied to cardinal Richelieu, in order to obtain a ceſſation of hoſtilities. His mode of attack, and ſtyle of preaching, may be diſcovered in the following paſſages, extracted from his ſermons. "Fathers," ſays he, in a diſcourſe delivered before the Cordeliers on St. Francis's day; "Admire the greatneſs of your ſaint; his miracles ſurpaſs thoſe of the Son of God. Jeſus Chriſt, with five loaves and three fiſhes, only once in his life, fed 5000 perſons: St. Francis, with an ell of cloth, by a perpetual miracle, feeds daily 40,000 ſluggards." "My friends," ſuch was his delicate ſatire on another occaſion, "a young gentleman is recommended to your charity, who is not rich enough to make a vow of poverty." The biſhop, with a view of checking the ardour for reading romances, which prevailed in his time, and of directing it to ſome uſeful purpoſe, compoſed a number of rival works of a pious nature and tendency, which in ſome degree anſwered the purpoſe. After performing his epiſcopal duties with zeal and diligence for 20 years, he reſolved to withdraw from the world; and having obtained leave to reſign his biſhopric, he retired firſt to the abbacy of Aulney, and afterwards to the hoſpital of Incurables at Paris, where he died in 1652, after refuſing two conſiderable biſhoprics. Camus was diſtinguiſhed by a lively and warm imagination; and he compoſed with wonderful facility, in a ſtyle that was partly grave and partly burleſque, abounding with ſingular metaphors and images, often ſtriking and ſometimes ludicrous. He is ſaid to have written 200 volumes, conſiſting of homilies and tracts, moral and devotional, pieces againſt the monks, pious novels, paſtoral directions, &c. His works, that are now read are, "L'Eſprit de S. François de Sales," 6 vols. 8vo. reduced to one by a doctor of the Sorbonne; and "L'Avoiſinement des Proteſtans avec l'Egliſe Romaine," republiſhed in 1703 by Richard Simon, under the title of "Moyens de reunir les Proteſtans avec l'Egliſe Romaine." Simon aſſerted, that Boſſuet's expoſition

poſition of the Cathólic faith was no more than this work in a new dreſs. Moreri. Nouv. Dict. Hiſt.

Camus, Stephen le, a French prelate, diſtinguiſhed by his penitence, mortification, and attention to the duties of his profeſſion, was born at Paris in 1632, and became a doctor of the Sorbonne in 1650. In early life he was borne away by the torrent of court diſſipation; but reſolving on reformation, he was nominated by the king in 1671, after having been his almoner for ſeveral years, to the biſhopric of Grenoble. His general conduct correſponded to the outward tokens of penitence which he manifeſted. "He always wore a rough hair-ſhirt and lay upon ſtraw. He roſe at two in the morning, recited his breviary, read the Scriptures, and at five called up a domeſtic who wakened the others. At half paſt five he read the common prayers, recited prime at ſix, and then ſaid maſs. He then retired to his cloſet till nine, when he gave audience. At eleven he dined with his houſehold. His chaplain ſat next him; and at another table were his ſteward and domeſtics. One of the lacqueys read. To the prelate were ſerved legumes only, with a ſmall meaſure of wine, half of which was reſerved for the deſſert. He went to reſt at eight. Such was the mode of living of this man, who was a prince as well as a biſhop." Some time before his death, when his bodily infirmities increaſed, an order was procured from the pope to add fiſh and fleſh to his diet. In viſiting his dioceſe, for which he devoted three months in every year, he commonly travelled on foot; and viſiting 100 pariſhes in a year, he completed his tour of the whole in three years. He everywhere preached with the ſame zeal, and diſtributed alms to the utmoſt extent of his revenue. He founded a number of charitable eſtabliſhments. In 1686 pope Innocent XI., from a mere regard to his virtues, advanced him to the cardinalate. He died in 1707, and made the poor his heirs. His publications were Paſtoral Letters to his Clergy, a collection of excellent Synodal Ordinances, and a Diſſertation in proof of the perpetual virginity of the virgin Mary. Moreri.

Camus, in *Ancient Geography*, a town of Aſia, placed by Polybius in Cæleſyria.

CAMYROS, in *Ancient Geography*. See Camiro.

CAN, in *Sea-Language.*—A pump's *can*, is a ſort of wooden jug or pitcher, wherewith ſeamen pour water into pumps to make them work.

Can-*buoy*. See Buoy.

Can-*hook*, an inſtrument uſed to ſling a caſk by the ends of the ſtaves: it conſiſts of a broad and flat hook fixed to each end of a ſhort rope, and the tackle which ſerves to hoiſt or lower it is faſtened to the middle of the rope.

CANA, in *Entomology*, an European ſpecies of apis, of a grey colour, with the ſegments of the abdomen edged with whitiſh. Muſ. Leſk.

Cana, in *Ornithology*, a ſpecies of motacilla, of a cinereous colour; with the quill feathers edged with whitiſh; tail feathers black, the exterior ones nearly all white. Gmel. &c.

Obs. This is the grey-throated warbler of the Arctic Zoology. Buffon calls it Figuier cendré à gorge cendrée. It inhabits Louiſiana.

Cana, in *Ancient Geography*, the name of two cities of Galilee in Paleſtine; one called by Jerom *Cana the Greater;* the other, *Cana the Leſſer*, or commonly Cana of Galilee. The former is mentioned by Joſhua (chap. xix. 28.) and was ſituated in the tribe of Aſher; the latter, which is more frequently mentioned in the ſacred writings, (See John II. i. 11. iv. 46. xxi. 2.) was ſeated in the tribe of Zebulun, N.W. of the ſea of Galilee or of Tiberias, or the lake of Genneſareth, on the confines of the upper and lower Galilee. This was the country of the apoſtle Simon, hence called the Canaanite (Matt. x. 4.) and of Nathaniel (John xxi. 2.); here Jeſus wrought his firſt miracle; and as it was ſituated to the north of Capernaum, he is ſaid to have gone down from Cana to this city; and after his return thither, the nobleman whoſe ſon was ſick at Capernaum viſited him there. It is of this Cana that Joſephus ſpeaks in his Life: p. 1005 and 1029.

Cana, or Kanah, a town of Paleſtine in the tribe of Ephraim, according to Euſebius and Jerom; and alſo a river of the ſame name on the weſtern limit of the territory of the Ephraimites. Joſh. xvi. 8. xvii. 9.

Cana, a promontory of Æolia, with a ſmall town and mountain adjoining to it, at the termination of the bay of Adramyttium.

Cana, a town in Cœleſyria. See Canath.

Cana, in *Geography*, one of the ſmaller weſtern iſlands of Scotland, about 8 miles S.W. from the iſland of Skye. N. lat. 57° 49'. W. long. 6° 40'.

Cana, El, a town of Aſiatic Turkey, in the province of Aladulia; 36 miles S. W. of Malatia.

CANAAN, in *Scripture Biography*, the fourth or youngeſt ſon of Ham, according to the order in which his name is introduced in Geneſis, ch. x. 6. The Hebrew word כנען is derived from כנע, to *humble* or *abaſe*, and with the נ *nun* ſervile it denotes a *merchant* or *trader*, as the Canaanites or Phœnicians were. If we join the כ and נ, or *ch* and *n* into one ſyllable, and pronounce it as the Jews do, the word will be Chnaan, and it will more nearly reſemble the Chna of Sanchoniatho and Stephanus Byzantinus. The time of his birth and the length of his life are not known; but ſome have ſuppoſed that he was born in the ark during the period of the deluge, and it has been fancifully ſaid that he was a wicked man, becauſe he was the fruit of an unſeaſonable incontinence. The irreverent action of Ham in diſcovering the nakedneſs of his father Noah was retaliated on Canaan. To this purpoſe Noah, with the ſpirit of prophecy, pronounces his malediction on this branch of his poſterity, "Curſed," ſays he, "be Canaan; a ſervant of ſervants ſhall he be unto his brethren." Gen. ix. 25. As this curſe was denounced, not againſt Ham the immediate trangreſſor, but againſt his ſon, who does not appear, from the words of Moſes, to have been at all concerned in the crime, many conjectures have been employed to ſolve this difficulty in the ſacred hiſtory. Some commentators apply the term קטן, or younger ſon in ch. ix. 24. to Canaan; and imagine that he joined with his father Ham in this mockery and inſult upon Noah; and the Jewiſh rabbins have a tradition, that Canaan was the firſt who ſaw Noah in this poſture, and then went and called his father Ham and concurred with him in his act of irreverence. Origen in Geneſ. p. 33. vol. ii. ed. Benedict. Bocharti Phaleg. l. iv. c. 37. col. 308. But this is a very arbitrary and unfounded method of interpretation; becauſe no previous mention was made of Canaan, and of what he had done, but only of Ham the father of Canaan; and of him, therefore, the phraſe of "little ſon" or "youngeſt ſon" muſt be underſtood. Others have alleged, that this curſe was ſo far from being pronounced upon Canaan for his father Ham's trangreſſion that it was not pronounced for his own, nor was it executed ſeveral hundred years after his death. It is in reality to be underſtood not ſo properly of Canaan, as of his deſcendants, the Canaanites. Accordingly, it is ſaid, that God, foreſeeing the wickedneſs of this people, which began with their father Ham, and greatly increaſed in this branch of his family, commiſſioned Noah to pronounce a curſe upon them, and to devote them to the ſervitude and miſery, which their more common vices and iniquities would deſerve. It is added, that this account was written by Moſes for the encouragement of the Iſraelites, to ſupport and animate them in their expedition againſt a people, who by their ſins had forfeited the divine protection, and were deſtined to ſlavery from the days of Noah.

Some biblical critics have propoſed to correct the text, ſuppoſing that Canaan is here erroneouſly placed for Ham, which is the reading of the Aldine edition of the LXX. and of 7 of Holmes's MSS. Others ſuppoſe that חם אבי, *Ham the father of*, are wanting before Canaan, and ſupply them accordingly; partly from the Arabic verſion כנעאן אבו, and partly from the rules of Hebrew metre, laid down by biſhop Hare; חם אבי being neceſſary to fill up the verſe. But neither of theſe authorities, ſays Dr. Geddes, is ſufficient to juſtify an alteration in the preſent text, in which there is no variety of reading either in the Samaritan or Hebrew copies, and with which all the other ancient verſions perfectly agree. Beſides, if this alteration were allowed, it would not much mend the matter; for if Ham was only to be curſed, why curſe him under the denomination of the father of Canaan. The text, in Dr. Geddes's opinion, is ſufficiently clear as it ſtands; and highly expreſſive of what we may ſuppoſe to have been the feelings of Noah on this occaſion. On awakening, he learns that Ham had uſed him moſt irreverently, while his other ſons had ſhewed him that filial regard which was due to ſuch a venerable father. To expreſs his indignation at ſo infamous a conduct, he curſes Ham in his progeny, and in *him* of his progeny, who was, probably, moſt dear to him, as being his youngeſt ſon, perhaps juſt then born; and whoſe very name, which imports the idea of depreſſive humiliation, might readily offer a paronomaſiacal alluſion, ſo common in the maledictions and benedictions of the patriarchs. Dr. Geddes proceeds with reflections which we can by no means approve, and which, in our opinion, are altogether unneceſſary to vindicate this part of the Scripture hiſtory. "Whether this malediction," he ſays, "were prophetic or imprecatory; whether it were really made by Noah, or whether the whole be not a poſtliminious tale, contrived by the Hebrew hiſtoriographer for the purpoſe of throwing an odium on the Canaanites, and juſtifying the conqueſt of their country; are points which I mean not now to diſcuſs: but it is pretty clear, that the ſtory, true or falſe, is here introduced, to pave the way for a more ſpecial command from heaven to conquer and extirpate the Canaanite nations." See CANAANITES.

The curſe pronounced by Noah on Canaan was peculiar to this ſon of Ham and his poſterity, and does not ſeem to have extended to the reſt of his brethren. And, indeed, conſidered as a prophecy, the declaration that Canaan "ſhould be a ſervant of ſervants to his brethren," ſeems to have been wholly completed in him, though its accompliſhment was diſtant and gradual. It was completed with regard to Shem, not only becauſe a conſiderable part of the ſeven nations of the Canaanites were made ſlaves to the Iſraelites, when they took poſſeſſion of their land, as part of the remainder of them were afterwards enſlaved by Solomon; but alſo by the ſubſequent expeditions of the Aſſyrians and Perſians, who were both deſcended from Shem; and under whom the Canaanites ſuffered ſubjection, as well as the Iſraelites; not to mention the conqueſt of part of Canaan by the Elamites, or Perſians, under Chedorlaomer, prior to them all. With regard to Japheth, we find a completion of the prophecy, in the ſucceſſive conqueſts of the Greeks and Romans in Paleſtine and Phœnicia, where the Canaanites were ſettled; but eſpecially in the total ſubverſion of the Carthaginian power by the Romans; beſides ſome invaſions of the northern nations, as the poſterity of Thogarmah and Magog: wherein many of them were, probably, carried away captive. "Egypt," ſays biſhop Newton, "was the *land of Ham*, as it is often called in Scripture; and for many years it was a great and flouriſhing kingdom; but it was ſubdued by the Perſians and afterwards by the Grecians, and it has ever ſince been in ſubjection to ſome or others of the poſterity of Shem or Japheth. The whole continent of Africa was peopled principally by the children of Ham; and for how many ages have the better parts of that country lain under the dominion of the Romans, and then of the Saracens, and now of the Turks? In what wickedneſs, ignorance, barbarity, ſlavery, miſery, live moſt of the inhabitants? And of the poor negroes how many hundreds every year are ſold and bought like beaſts in the market, and are conveyed from one quarter of the world to do the work of beaſts in another?" "Nothing," ſays this prelate in the cloſe of his account of this prophecy, "can be more complete than the execution of the ſentence upon Ham as well as upon Canaan."

Canaan is ſuppoſed to have lived and died in a country called after his name. His poſterity was very numerous. His eldeſt ſon Sidon founded the city of Sidon, and was the father of the Sidonians and Phœnicians. His ten other ſons were the fathers of as many tribes, dwelling in Paleſtine and Syria: viz. the Hittites, Jebuſites, Amorites, Girgaſites, Hivites, Arkites, Sinites, Arvadites, Zemarites, and Humathites.

Canaan ſeems to have been known to the ancient heathens. Sanchoniatho occaſionally mentions Cnaa, who is known to be Canaan, as the firſt Phœnician. There is reaſon to think, ſays the learned Bryant, that by the Egyptians and other neighbouring nations, Canaan was expreſſed Cnaan. This by the Greeks was rendered χναας, and χνας; and in later times χνα, Cna. Bryant adds, that, by prefixing the term Υκ, uc, which is to be found in the compoſition of many words, particularly ſuch as are of Amonian original, Cnas or Canaan, was ſtyled Uc-nas, and the Gentile name or poſſeſſive was Uc-cnaos, Υκ κναος, which was changed by the Greeks into Κυκνειος, or Cucneus; and from Υκ Κνας they formed Κυκνος. Hence he derives the Cycnus of Lucian and the ancient poets, who was repreſented as the brother of Phaethon and transformed into a ſwan. With reſpect to Cycnus and his brotherhood, the vocal miniſters of Apollo, the ſtory, as he conceives, which is told of them undoubtedly alludes to Canaan, the ſon of Ham, and to the Canaanites, his poſterity. Accordingly he obſerves, that the ſwan was the enſign of Canaan, as the eagle and vulture were of Egypt, and the dove of Babylonia: and that, wherever we may imagine any colonies from Canaan to have ſettled and founded temples, there is ſome ſtory about ſwans. The Canaanites, it is ſaid, wherever they came, introduced their national worſhip; part of which conſiſted in chanting hymns to the honour of their country god, who was the ſame as Apollo of Greece; and on this account Lucian, in compliance with the current notion, ſays, that the Cycni were formerly the aſſeſſors and miniſters of that deity. By this, ſays Bryant, we are to underſtand, that people of this denomination were in ancient times his prieſts. Mede's works, vol. i. p. 378. Anc. Un. Hiſt. vol. i. p. 88. Geddes's Crit. Rom. vol. i. p. 76. Biſhop Newton on the Prophecies in his works, vol. vii. p. 11—23. 8vo. Leland's Deiſtical Writers, vol. iii. p. 254, &c. Bryant's Anal. Anc. Mythol. vol. i. p. 369, &c.

**CANAAN**, *land of*, in *Scripture Geography*, ſo named from

Canaan, the ſon of Ham, whoſe poſterity poſſeſſed this country as well as Egypt, or Mizraim, lies in the weſtern part of Aſia, and extends from about 31° to 33° 20′ N. lat. and from 34° 50′ to 37° 15′ E. long. It was bounded, to the north, by Cæle-Syria, or the mountains of Libanus and Anti-Libanus; to the weſt, by the Mediterranean ſea; to the eaſt, by Arabia Deſerta; and to the ſouth and ſouth-weſt, by Arabia Petræa and Egypt. Its extent has been variouſly aſcertained; but from the lateſt and moſt accurate computation, it was about 200 miles from north to ſouth, that is, from Dan or Cæſarea-Philippi to Beer-ſheba, and about 100 miles in breadth. According to this reduced extent, if we conſider its extraordinary fertility, the number of its inhabitants, and the many cities and villages which it contained, it was ſo far from being an inconſiderable ſpot of ground, as ſome have miſrepreſented it, that, excluſive of what it was in the reigns of David and Solomon, (Ezra, iv. 20.) and many ages after, it muſt have been always regarded as one of the moſt opulent and conſiderable kingdoms of the Eaſt; and it muſt be allowed, that the Iſraelites, according to the acknowledgment of the king of Tyre, (1 Kings, v. 7.) were a "great people." Indeed, the deſcription of its wealth, power, and population, ſeems very extraordinary; even allowing it to have been cultivated with the utmoſt diligence, by men well acquainted with every branch of agriculture.

Before the Iſraelites obtained the poſſeſſion of it, Moſes deſcribes it as a country ſingularly fertile and productive. See Deut. viii. 7, &c. Its wonderful fecundity was owing to ſeveral circumſtances; ſuch as the excellent temperature of the air, which was never ſubject to exceſſive heats or colds, the regularity of its ſeaſons, eſpecially the former and latter rain, and the natural fatneſs and fertility of its ſoil, which required neither dunging nor manuring. It was famous for its large and delicious grapes, for its palm-trees, and its dates, for its balſam ſhrub which produced the celebrated balm of Gilead, for the conſtant verdure of its fruit trees, and for its citrons and its oranges. Its vines yielded grapes twice, and ſometimes thrice, in a year; its honey was abundant; its inhabitants cultivated ſugar-canes with great aſſiduity; and their cotton, hemp, and flax, were moſtly of their own growth and manufacture. Its vicinity to Libanus afforded them an ample ſupply of cedars, cypreſſes, and other ſtately and fragrant trees. They fed large herds of cattle, both great and ſmall, and their hilly country afforded them not only variety and plenty of paſture, but alſo of water, that deſcended thence into the vallies and low lands, which it fertilized. But the moſt fertile paſture-grounds were on each ſide of the river Jordan, beſides thoſe of Sharon, or Sarona, the plains of Lydda, Jamnia, and ſome others, which were then juſtly famed for their fecundity. As for fiſh, their rivers, the lake of Tiberias, and the Mediterranean ſea, afforded great plenty and variety. The lake Aſphaltites yielded abundance of ſalt, with which they ſeaſoned and preſerved their fiſh, and which Galen affirms to have been preferable to any other. It ought further to be conſidered, that the country was then inhabited by an induſtrious people, who knew how to improve every inch of this land, and had made even the moſt deſert and barren places to yield ſome kind of produce, by proper care and manure, ſo that the very rocks, which now appear quite naked, produced corn, pulſe, or paſture; for every little hillock was formed into a terrace covered with mould, which, through the lazineſs of ſucceeding proprietors, has been ſince waſhed off by rains and ſtorms. The fecundity of Paleſtine hath been extolled even by Julian the apoſtate, a ſworn enemy to Jews and Chriſtians, who frequently, in his Epiſtles, mentions the perpetuity, as well as excellence and great abundance of its fruits and produce. The viſible effects of divine diſpleaſure, which this country has felt, not only under Titus Veſpaſian, but much more ſince that emperor's time, in the inundations of the northern barbarians, of the Saracens, and of the more cruel and deſtructive Chriſtians, during the holy war, and in the oppreſſion it now feels under the Turkiſh yoke, are cauſes more than ſufficient to have reduced the far greater part of the country into a mere deſert. If we were to judge by its preſent appearance, nature itſelf has rendered it incapable of cultivation.

The land of Canaan was divided into two unequal parts, of which the weſtern was conſiderably the greater, by the river Jordan, which riſes in the mountains of Hermon (a branch of the mountains of Libanus), and running ſouth through the lake of Genneſareth, or the ſea of Tiberias and Galilee, after a courſe of 150 miles, loſes itſelf in the Aſphaltite Lake, or the Dead Sea. See ASPHALTITE *Lake*.

The country to the eaſt of Jordan was given to the tribes of Reuben, Gad, and the half tribe of Manaſſeh; the kingdom of Moab lay to the ſouth; the kingdom of Ammon to the eaſt of Gad; and the mountains of Hermon bounded Manaſſeh to the north-eaſt, beyond which lay Trachonitis and Ituræa. Weſt of the Jordan, to the north, were placed Naphtali on the river, and Aſher, which bordered on Phœnicia and the Mediterranean. Zebulun and Iſſachar had inland diſtricts; but the other half tribe of Manaſſeh and Ephraim reached from the ſea to the river. Dan (upon the coaſt) and Benjamin, were ſouth of Ephraim, and north of Simeon and Judah. The country allotted to Simeon bordered upon the Mediterranean, and extended to Egypt; but the Philiſtines, who inhabited the coaſt, were never entirely driven out of their poſſeſſions. The country of Judah bordered upon the Dead Sea, which ſeparated it from the kingdom of Moab (for both Simeon and Judah lay conſiderably more ſouth than the tribe of Reuben), and adjoined the mountainous country of Idumæa, or Edom, and Arabia Petræa, to the ſouth. The next remarkable diviſion, next to the diſtribution, by lot, among the twelve tribes, was made by king Solomon, who divided his kingdom into 12 provinces, or diſtricts, each under a peculiar officer; but the moſt fatal diviſion of all was that which obtained under his imprudent ſon Rehoboam, when ten of the twelve tribes revolted, under the conduct of Jeroboam, who became head of this new monarchy, ſtyled the kingdom of Iſrael, in oppoſition to that of Judah, the title which diſtinguiſhed the maimed kingdom of Rehoboam, from that time downwards. Under the ſecond temple the diſtinction laſted a conſiderable time, and the ſame ſanguinary hatred and hoſtilities continued between theſe two kingdoms; that of Iſrael taking the name of Samaria, from its capital. See SAMARIA.

After the return from the Babylonian captivity, the eaſtern diviſion of the land of Canaan was called Peræa (more properly the country which had belonged to Reuben and Gad, for the northern part, ſometimes called Gaulonitis, was included in the diſtrict of Trachonitis), and the weſtern part was divided into Galilee to the north, Judæa to the ſouth, and Samaria in the middle. See each of theſe articles. Judæa Proper extended from the Dead Sea and the Mediterranean to Egypt, and included the countries of Benjamin, Dan, and Simeon, beſide that of Judah. Under the Romans the land began to be divided into tetrarchies and toparchies: the larger were thoſe of Judæa, Samaria, and Galilee, upper and lower; the leſſer, thoſe of Geraritica, Sarona, and others of leſs note; all which lay on this ſide of the Jordan. The reſt, on the other ſide, were thoſe of Gilead, Peræa, Gaulonitis, Auranitis, Batanea, and Decapolis. Joſephus (Antiq. l. xiv. c. 10.) mentions another diviſion, made in the time of Gabinius, into five diſtricts, or, as he ſtyles them, συνέδρια, or councils, agreeably to the Roman manner; theſe were Jeruſalem, Jericho, and Sephoris, on this ſide of Jordan; and Gadaris and Amathus on the other. The whole country was alſo called Palestine (which ſee), from the Paleſtines or Philiſtines, who inhabited the weſtern coaſts, and were firſt known to the Romans; but it was more commonly called Judæa (which ſee), or Judæa Paleſtina, from Judah, whoſe tribe was the moſt conſiderable of the twelve, and poſſeſſed the fineſt and moſt fertile part of the whole. Chriſtians, as well as Jews, have dignified it with the title of "Holy Land;" partly on account of its metropolis, ſuppoſed to have been the centre of God's worſhip, and his peculiar habitation; but chiefly for its being the native country of Jeſus Chriſt, and the ſcene on which he accompliſhed the great work of our redemption. It has alſo been diſtinguiſhed by other appellations: ſuch as the "Land of Promiſe," the "Land of God," the "Land of Iſrael," and ſometimes, by way of pre-eminence, "the Land." In modern writers, all diſtinction is frequently loſt in the general name of Syria, which is given to the whole country eaſt of the Mediterranean, between the ſea and the deſert. As many of the old inhabitants of the north-weſt of the land of Canaan, particularly on the coaſts of Tyre and Sidon, were not driven out by the children of Iſrael, this tract ſeems to have retained the name of Canaan a long while after thoſe other parts of the country, which were better inhabited by the Iſraelites, had loſt the ſaid name. The Greeks called this tract, inhabited by the old Canaanites, along the Mediterranean ſea, Phœnicia (which ſee); the more inland parts, as being inhabited partly by Canaanites, and partly by Syrians, Syro-Phœnicia; and hence the woman ſaid by St. Matthew (ch. xv. 22.) to be a woman of Canaan, whoſe daughter Jeſus cured, is ſaid by St. Mark (ch. vii. 26.) to be a Syro-Phœnician by nation, as ſhe was a Greek by nation and language. The principal mountains of the land of Canaan or Paleſtine are Libanus or Lebanon, Anti-Libanus, Hermon, Tabor, Carmel, Olivet, Calvary, Moriah, and Gihon, which ſee reſpectively. The moſt noted vallies were the valley of Bleſſing, or Berakhah, in the tribe of Judah, on the weſt ſide of the lake of Sodom, and in the wilderneſs of Tekoah; the vale of Siddim, famed for the overthrow of Chedorlaomer and his confederate kings (Gen. xiv. 2, &c.), and for the cities of Sodom and Gomorrah, now forming the Aſphaltite lake; the valley of Shaveh, or royal valley, where the king of Sodom met victorious Abraham, after the defeat of the confederate kings; the vale of Salt, in which the Edomites were ſubdued by David and Amaziah (2 Sam. viii. 13. 2 Kings, xiv. 7.); the valley of Jezreel, famed for the death of Jezebel, the idolatrous wife of Ahab; the valley of Mamre, famous for the oak under which Abraham dwelt, about 15 miles from Hebron, and 25 from Jeruſalem; the vale of Rephaim, or of the Titans and Giants, near the city of Jeruſalem; the vale of Jehoſhaphat, in or near Jeruſalem; the valley of Hinnom, near the walls of Jeruſalem, notorious for the ſuperſtitious and bloody rites performed there in ancient times; the valley of Zeboim, near the Dead Sea; the valley of Achor, near Jericho; the valley of Bochim, or of the mourners (Judg. ii. 1, &c.), at a ſmall diſtance from Jeruſalem; and the valley of Elah, famous for the defeat and death of Goliath by David, and for the victory which the Iſraelites obtained againſt the Philiſtines (1 Sam. xvii. 2, &c.). The country had alſo ſeveral noted plains, the moſt remarkable of which is that through the midſt of which lay the courſe of the river Jordan, computed to be about 150 miles in length, from the city of Scythopolis northward to the Aſphaltite lake. In this country were alſo ſeveral foreſts, ſuch as thoſe of Hareth, of Ephraim, of Lebanon, in which Solomon had a ſumptuous palace, and of Bethel. The ſeas of Canaan are commonly reckoned five; viz. the Mediterranean, called by the ſacred writers the Great Sea; the Dead Sea or lake of Sodom; the Sea of Tiberias; the Samachonite Sea or lake; and the Sea of Jazer. The moſt conſiderable river is Jordan, which ſee. For a further account of this country and its inhabitants, ſee Canaanites and Palestine.

Canaan, in *Geography*, a thriving townſhip of America, in Lincoln county, and diſtrict of Maine, ſeated on Keanebeck river, about ſeven miles north of Hancock, incorporated in 1788, and containing 454 inhabitants.—Alſo, a townſhip of Grafton county, in New Hampſhire, 10 miles E. of Dartmouth college; incorporated in 1761, and containing, in 1790, 483 inhabitants.—Alſo, a townſhip of Litchfield county, in Connecticut, E. of Houſatonick river, with Maſſachuſetts on the north. It has a forge and ſlitting mill, and furniſhes excellent iron. The mountains a[illegible]ble minerals, particularly lead and iron. It is diſtant 60 miles from New Haven, and 40 N.W. from Hartford.—Alſo, a townſhip of Eſſex county, in Vermont, being the north-eaſtermoſt town in the ſtate.—Alſo, a townſhip of Columbia county, in New York, between Kinderhook on the weſt, and Maſſachuſetts on the eaſt. It has 6692 inhabitants, including 35 ſlaves.

CANAANITES, in *Scripture Hiſtory*, the poſterity of Canaan by his eleven ſons, who are ſuppoſed to have ſettled in the land of Canaan, ſoon after the diſperſion of Babel. Five of theſe are known to have dwelt in the land of Canaan; viz. Heth, Jebus, Hemor, or Amor, Girgaſhi, and Hevi or Hivi; and theſe, together with their father Canaan, became the heads of ſo many nations. Sina or Sini was another ſon of Canaan, whoſe ſettlement is not ſo preciſely aſcertained; but ſome authors infer, from the affinity of the names, that the deſert of Sin, and mount Sinai, were the place of his abode, and that they were ſo called from him. The Hittites inhabited the country about Hebron, as far as Beer-ſheba, and the brook Beſor, reckoned by Moſes the ſouthern limits of Canaan. The Jebuſites dwelt near them on the north, as far as the city of Jebus, ſince called Jeruſalem. The Amorites poſſeſſed the country on the eaſt ſide of Jordan, between the river Arnon on the ſouth-eaſt, and mount Gilead on the north, afterwards the lot of Reuben and Gad. The Girgaſhites lay next above the Amorites, on the eaſt ſide of the ſea of Tiberias, and their land was afterwards poſſeſſed by the half tribe of Manaſſeh. The Hivites dwelt northward, under mount Libanus. The Perizzites, who make one of the ſeven nations of the Canaanites, are ſuppoſed, by Heylin and others, to be the deſcendants of Sina or Sini; and it is probable, ſince we do not read of their abode in cities, that they lived diſperſed, and in tents, like the Scythians, roving on both ſides of the Jordan, on the hills and plains; and that they were called by that name from the Hebrew, *pharatz*, which ſignifies to *diſperſe*. The Canaanites dwelt in the midſt of all, and were ſurrounded by the reſt. This appears from the ſacred writings to have been the reſpective ſituation of thoſe ſeven nations, which are ſaid to have been doomed to deſtruction for their idolatry and wickedneſs, when the Iſraelites firſt invaded their country. The learned have not abſolutely determined whether the nations proceeding from

Canaan's other ſix ſons ſhould be reckoned among the inhabitants of the land of Canaan. The prevalent opinion is, that they were not included. As to the cuſtoms, manners, arts, ſciences, and language of the ſeven nations, that inhabited the land of Canaan, they muſt, from the ſituation they ſeverally occupied, have been very different. Thoſe who inhabited the ſea-coaſt were merchants, and by reaſon of their commerce and wealth ſcattered colonies over almoſt all the iſlands and maritime provinces of the Mediterranean. See Phœnicia. The colonies which Cadmus carried to Thebes in Bœotia, and his brother Cilix into Cilicia, are ſaid to have proceeded from the ſtock of Canaan. Sicily, Sardinia, Malta, Cyprus, Corfu, Majorca, Minorca, Gades, and Ebutris, are ſuppoſed to have been peopled by the Canaanites. (See Bochart's Canaan.) The other Canaanites, whoſe ſituation was inland, were employed partly in paſturage, and partly in tillage, and they were alſo well ſkilled in the exerciſe of arms. Thoſe who dwelt in the walled cities, and who had fixed abodes, cultivated the land; and thoſe who wandered about, as the Perizzites ſeem to have done, grazed cattle, or carried arms: ſo that among the Canaanites, we diſcover the various claſſes of merchants, and, conſequently, mariners; of artificers, ſoldiers, ſhepherds, and huſbandmen. We learn, alſo, from their hiſtory, that they were all ready, however diverſified by their occupations or local intereſts, to join in the common cauſe: that they were well appointed for war, both offenſive and defenſive; that their towns were well fortified; that they were ſufficiently furniſhed with military weapons and warlike chariots; that they were daring, obſtinate, and almoſt invincible; and that they were not deſtitute of craft and policy. Their language, we find, was well underſtood by Abraham, who was an Hebrew, for he converſed readily with them on all occaſions; but as to their mode of writing, whether it was originally their own, or borrowed from the Iſraelites, it is not ſo eaſy to determine. Their religion ſeems to have been preſerved pure till the days of Abraham, who acknowledged Melchiſedek to be prieſt of the moſt high God; and Melchiſedek was, without doubt, a Canaanite, or, at leaſt, dwelt at that time in Canaan, in high eſteem and veneration.

But we learn from the ſcripture hiſtory, that the Hittites in particular were become degenerate in the time of Iſaac and Rebekah; for they could not endure the thoughts of Jacob's marrying one of the daughters of Heth, as Eſau had done. About this time, then, we may date the origin of thoſe abominations which ſubjected them to the divine diſpleaſure, and made them unworthy of the land which they poſſeſſed. In the days of Moſes, they were become incorrigible idolaters; for he commands the Iſraelites "to deſtroy their altars, and break down their images (ſtatues or pillars), and cut down their groves, and burn their graven images with fire." And leſt they ſhould pervert the Iſraelites, the latter were ſtrictly enjoined not to intermarry with them; but "to ſmite them, and utterly deſtroy them, nor ſhew mercy upon them." Deut. vii. 1—5. They are accuſed of the cruel cuſtom of ſacrificing men, and are ſaid to have paſſed their ſeed through fire to Moloch. Levit. xviii. 21. Their morals were as corrupt as their doctrine; adultery, beſtiality of all ſorts, profanation, inceſt, and all manner of uncleanneſs, are the ſins laid to their charge. The Canaanites, ſays Mr. Bryant, (Anal. Anc. Mythol. vol. i. p. 371.) as they were a ſiſter tribe of the Mizraim, reſembled them in their rites and religion. They held a heifer, or cow, in high veneration, agreeably to the cuſtoms of Egypt. Their chief deity was the ſun, whom they worſhipped, together with the Baalim, under the titles of Ourchol, Adonis, or Thamuz. The Canaanites, at Byblus, Berytus, Sidon, and afterwards at Tyre, uſed, in imitation of the Egyptians, mournful dirges for the loſs of Adonis or Thamuz, who was the ſame as Thamas and Oſiris in Egypt; and their meaſures and harmony ſeem to have been very affecting, and to have made a wonderful impreſſion on the minds of their audience. This infectious mode of worſhip prevailed to ſuch a degree, that the children of Iſrael were forbidden to weep, and make lamentation upon a feſtival. See Nehem. viii. 9. 11. Joſeph. Antiq. l. xi. c. 5. p. 563. Among the Canaanites, this manifeſtation of ſorrow was encouraged, and made part of their rites.

As to the government of the Canaanites, they ſeem to have been comprehended in a great number of ſtates, under ſubjection to limited chiefs, or kings, as they are called; and tranſacted all their buſineſs in popular aſſemblies.

When the meaſure of the idolatries and abominations of the Canaanites was compleated, God delivered their country into the hands of the Iſraelites, who conquered it under Joſhua. However, they reſiſted with obſtinate valour, and kept Joſhua employed ſix years, from the time of his paſſing the river Jordan, and entering Canaan, in the year B. C. 1451, to the year B.C. 1445, the ſabbatical year beginning from the autumnal equinox; when he made a diviſion of the land among the tribes of Iſrael, and reſted from his conqueſts. As God had commanded this people, long before, to be treated with rigour (See Deut. vii. 2.), Joſhua extirpated great numbers, and obliged the reſt to fly, ſome into Africa, and others into Greece. Procopius ſays, they firſt retreated into Egypt, but advanced into Africa, where they built many cities, and ſpread themſelves over thoſe vaſt regions, which reach to the ſtraits, preſerving their old language, with little alteration. In the time of Athanaſius, the Africans ſtill ſaid they were deſcended from the Canaanites; and when aſked their origin, they anſwered, "Canani." It is agreed, that the Punic tongue was nearly the ſame as the Canaanitiſh or Hebrew.

After the Canaanites had been ſucceſſively defeated, and, at length, diſperſed and reduced, the Anakims, a fierce and barbarous race, who inhabited ſome of the mountains of the land, of a diſtinct origin from the Canaanites, were invaded and cut off; and thus, by degrees, the Iſraelites became maſters of the greateſt part of the land of Canaan. However, the Canaanites of ſeveral denominations were ſtrong and powerful, and retained no mean ſhare of the country; and, for 19 or 20 years, the remainder of Joſhua's days, they were very little moleſted. At length, when the diviſion was completely ſettled, the Canaanites were, on all ſides, invaded again by the tribes of Iſrael, who wiſhed to drive them out of their reſpective lots. However, in the conflicts thus occaſioned, the contending parties ſeem to have been pretty equally matched; ſo that although multitudes of the Canaanites were ſlain in the wars with Joſhua, and many of them fled in queſt of more quiet habitations, yet, after all their calamities, they appear to have been little inferior to the Iſraelites; nor do we find that any one tribe of them was miſſing, except the Girgaſhites, who, it is ſaid, fled into Africa, and ſettled in that country. Thus it appears, that ſome of the more immediately devoted nations, viz. the Canaanites, Hittites, Amorites, Hivites, and Jebuſites, were allowed to dwell in common with the children of Iſrael in their promiſed land. See Judges, ch. i. ii. For this exerciſe of mercy and toleration reaſons of a political and religious nature have been aſſigned. Thus the Iſraelites were prevented from ſinking into a ſluggiſh and inactive ſtate, as they had enemies to excite and exerciſe their courage, and to to keep up among them martial diſcipline; they were thus preſerved in a condition of immediate dependance on God, and directed to look conſtantly to him for ſuccour; and it was thus provided, that no part of the country, which was too extenſive to be every where inhabited by the Iſraelites at their firſt ſettlement, ſhould be left deſolate, ſo as to become a refuge for wild beaſts, which, by their increaſe, might prove a more dreadful and pernicious enemy than the Canaanites. Beſides, it has been very juſtly alleged, that though the order for extermination was poſitive and abſolute, the promiſe of power to fulfil it was limited and conditional. It was not till after the Iſraelites had forſaken the Lord, and worſhipped other gods, that the Lord would no more enable them to expel the Canaanites. The Canaanites ſeem to have been able to have maintained their ground in ſeveral parts of the country, and particularly in Jeruſalem, till the reign of David; when that city, which had been held by the Jebuſites, was taken by ſtorm. They were alſo invaded in Gezer by Pharaoh; their city was burnt, and they were all put to the ſword. Thus oppreſſed by the Iſraelites on one hand, and by the mighty power of Egypt on the other, the remaining Amorites, Hittites, Perizzites, Hivites, and Jebuſites, were reduced, in the reign of Solomon, to a ſtate of ſlavery, and employed in the labour of carrying on his vaſt and ſumptuous works; and this ſeverity was entailed on their poſterity. 1 Kings, ix. 20, 21. Ezra, ii. 55. 58. Nehem. xi. 3. Although upon their firſt reduction, they became proſelytes to the Jewiſh religion, yet it has been thought, that they were diſtinguiſhed from the Jews, and reckoned of a more ignoble blood, born to drudgery. Among the tribes of the Canaanites above enumerated, who became ſubject to the yoke of Solomon, the Canaanites, peculiarly ſo called, are omitted. Theſe, we may therefore conclude, bore no part of the burden impoſed upon the others; but remained free and independent in their poſſeſſions on the ſea-coaſt, roſe afterwards to great celebrity, and, continually improving themſelves in navigation, commerce, and the uſeful arts, were compriſed under the appellation of Phœnicians. Anc. Un. Hiſt. vol. i.

The deſtruction of the Canaanites, and the expulſion of them from their country by a divine order, whilſt ſome of them were allowed to remain in oppoſition to this order, have afforded a theme, on which ſceptics and infidels have vehemently declaimed; and which they have urged as an unanſwerable objection either to the truth of the ſcripture hiſtory, or, admitting the fact, to the moral providence of God. This objection has been lately ſtated in its full force by a learned commentator and critic (Dr. Geddes) in the preface to the 2d volume of his "Tranſlation," and alſo in the 1ſt volume of his "Critical Remarks," p. 422, &c.; and inſtead of obviating it by argument, or admitting the ſufficiency of the ſolution of the difficulty, propoſed by other ingenious and learned writers, he boldly cuts the Gordian knot, reſpecting the order ſuppoſed to be given by God for the extermination of the Canaanites; deeming this method preferable to the unſucceſsful endeavours of other ſcriptural writers to untie it. Inſtead of acceding to any of the arguments which have been employed in defence, or even in extenuation, of this ſuppoſed cruel and ſanguinary meaſure, he denies that any ſuch order proceeded from God, or even from the mouth of Moſes. He ſuſpects it to be "the fabrication of ſome poſterior Jew, to juſtify the cruelties of his nation." Of courſe, he diſputes the abſolute and univerſal inſpiration of the Hebrew writers. It is beſide our purpoſe to enter at large into the diſcuſſion of this ſubject. But when we conſider, that the extermination of the Canaanites forms a leading and prominent part of the ſcripture hiſtory, and that it is, more directly or indirectly, referred to as the conſequence of a divine order, in a great variety of paſſages, the idea of the fabrication of ſuch an order by a poſterior Jew, ſeems to us to be altogether inadmiſſible. The account of this event, and of the circumſtances ſucceeding and attending it, pervades the whole Jewiſh hiſtory; and if we ſuppoſe that the providence of God had no concern in the conduct and execution of it, we muſt be led to admit a great number of fabrications and interpolations in the detailed account which the ſcripture has given us of it, and we ſhall ultimately undermine the truth of the hiſtory itſelf, and find it difficult to determine what part of it is authentic and true and what is forged and falſe. But we are of opinion, that the objection itſelf, which has been repeated by Tindal, Morgan, and Bolingbroke, and laſt of all by the author of the "Age of Reaſon," has been as often ſatisfactorily refuted. To this purpoſe it has been argued, that the Canaanites were guilty not only of the groſſeſt idolatries, but of the moſt execrable vices, ſome of which have been thought to deſerve death, and have been ſo puniſhed in all civilized countries. God expreſsly declares, after warning the Iſraelites againſt theſe abominable crimes, that becauſe of theſe things "he abhorred thoſe nations and caſt them out." Lev. xx. 23. It is plain then, that the wickedneſs of the Canaanites was the true cauſe of the puniſhment that was inflicted upon them; and accordingly it is given as a reaſon why they were not long before expelled and deſtroyed, that the "iniquities of the Amorites was not yet full." Gen. xv. 16. It was not, therefore, till the meaſure of their ſins was compleated, and their wickedneſs became univerſal and incorrigible, that the threatened judgment was inflicted. Now can it be denied, that God, who is the ſovereign arbiter of life, and who may, and actually does, whenever he pleaſes, take away men's lives without injuſtice, may in juſt judgment cut ſhort the lives of perſons for their crimes, and bring general deſtruction even upon communities of people or nations? Why, it may be aſked, ſhould the deſtruction of a ſmall part of the inhabitants of the earth be pronounced to be incompatible with the divine attributes, while the deſtruction of the whole world by the deluge is paſſed by without any comment? The general deſtruction of the human race in the latter caſe, and the partial extermination of the Canaanties, are to be accounted for upon preciſely the ſame principle. In both caſes it was the enormous wickedneſs of the people which drew upon them ſuch ſignal puniſhment. This kind of puniſhment of individual or national wickedneſs may ſerve the purpoſe of inſtructive example and warning to the world in general; and in the caſe before us it was highly expedient, and even neceſſary for the inſtruction of that age of mankind, that the Supreme Ruler ſhould make a ſignal and ſtriking example of a nation ſo far ſunk in idolatry and corruptions of all kinds, as all the inhabitants of Canaan are ſaid to have been. With reſpect to the mode of the puniſhment of the Canaanites, it may be obſerved, that if God had deſtroyed them by famine or by peſtilence, if he had cauſed fire from heaven to conſume them, or exterminated them by an inundation or an earthquake, none could have preſumed to arraign the wiſdom and juſtice of his proceedings; although in calamities of this public nature infants muſt have ſuffered as well as the parents; and among the adults ſome innocent individuals muſt have been involved in the common ruin. In ſuch a caſe it could not have been ſaid, that this was contrary to the law of nature, or that it was not conformable to the uſual conduct of Providence. But then it would not have been ſo apparent, that this calamity of their extermination was inflicted by way of puniſhment for their idolatry and deteſtable wickedneſs. It might poſſibly have been attributed to ſome natural cauſe, or have been regarded as an unaccountable and fortuitous event. But when they were ordered to be exterminated for their abominable crimes by an expreſs command of God, atteſted by a ſeries of the moſt amazing miracles and divine interpoſitions; and this was appointed to be executed by another nation, peculiarly ſet apart by their original conſtitution to the acknowledgment and worſhip of the one true God, and of him only, and to whom God had given the moſt excellent and holy laws, threatening them at the ſame time with ſimilar puniſhments if they committed the like crimes:—in this caſe, the reaſon of the judgment was as apparent as when a malefactor is put to death by an officer of juſtice for a crime, in execution of the ſentence of a juſt magiſtrate. Nor in ſuch a procedure is there any thing, that can be proved to be inconſiſtent with the wiſdom and righteouſneſs of the Supreme Being, or contradictory to his own laws; ſince there is no law of nature that debars God from executing judgments on particular perſons, or guilty nations, for their crimes and vices, even to extermination; or from employing, if he thinks fit, one or more nations to execute his judgments upon others. In this inſtance the word of God is in perfect harmony with his works and thoſe manifeſtations of the divine attributes that are diſcernible in the book of nature.

Although God cannot diſpenſe with the abſolute and immutable obligations of doing whatever is juſt and right; yet a command from God may either make or imply ſome change in the circumſtances and relations of things, on which the moral fitneſs of the human conduct depends, and conſequently it may be fit and right to do that in virtue of a divine command, which it would not have been fit to do without it.

Lord Bolingbroke, indeed, (vol. iii. p. 305. vol. v. p. 148.) has compared the invaſion of Canaan by the Iſraelites, and what they did there, to the cruelties exerciſed by the Spaniards in America, and to the ravages of the Huns under Attila, who, he ſays, were much more merciful than they; but he ſeems to forget the difference between theſe caſes; viz. that the latter had no motive or pretence, but their own ambition, avarice, and cruelty; whereas the former acted in execution of the expreſs command of God, and by a commiſſion from him, the truth of which was confirmed by a ſeries of the moſt extraordinary divine atteſtations that the world ever ſaw. This can, therefore, furniſh no precedent for any other nation to do the like, except they can produce the ſame or equal proofs of a divine commiſſion. The ſame general anſwer will ſuffice for obviating ſeveral of the inferences deduced from this event by Dr. Geddes, *ubi ſupra*. It would be a ſufficient reaſon for the extermination of the Canaanites by the ſword of the children of Iſrael, if, as is very poſſible, this was the beſt method of impreſſing the minds of the Iſraelites themſelves with a juſt idea of the heinous nature of idolatry, and to make ſufficient proviſion againſt their being ſeduced into the ſame abominable practices. If their living only in the neighbourhood of idolatrous nations was ſo unſafe for this people, as their hiſtory ſhews it to have been, what danger would they not have been in, if they had ſpared the old inhabitants of Canaan, and ſuffered them to live unmoleſted among them? It ought alſo to be conſidered, that in all the other wars in which the Iſraelites might happen to be engaged, with their neighbouring nations, they were expreſsly enjoined to purſue different and more humane maxims, ſparing all except ſuch as were found bearing arms. In this particular caſe only they were expreſsly commanded to "exterminate utterly." That the Iſraelites were not influenced by the uſual paſſions of conquerors, but acted under an authority which controuled their natural deſires, is manifeſt from their ſparing even the cattle, and even refraining to appropriate to themſelves the treaſure which they found in Jericho, which was the firſt fruits of their conqueſts, and to be devoted to God. The Iſraelites have often been compared to barbarous conquerors and cruel murderers; but let other conquerors and aſſaſſins be produced, who refrained from plunder as they did. That they were not actuated by mere rage and revenge is evident from their having received no particular provocation, not indeed having had any perſonal intercourſe with the inhabitants of Canaan. Their motives muſt, therefore, have been very different from thoſe of common robbers and murderers; and in the judgment of reaſon, it is the motive that determines the nature of the action. It is alſo remarkable, that notwithſtanding the paſſion which the Iſraelites may be ſuppoſed to have had for war, which would have been inflamed by the rapidity of their conqueſts, they were forbidden to extend them beyond the boundaries of the land of Canaan; and the conſtitution of their government was altogether unſuited to extenſive empire.

The learned Mr. Bryant in his Treatiſe on the authenticity of the Scriptures, (p. 245, &c.) argues againſt the objection which we have been conſidering, that the Canaanites were uſurpers, and had acted in direct defiance of an ordinance of God, by ſeizing upon the land appropriated from the beginning to the children of Iſrael. Moſes, accordingly, intimates, that the land of Canaan was their peculiar inheritance, Deut. xxxii. 7, 8. In the Euſebian Chronicle of Scaliger it is mentioned, that Canaan the ſon of Ham, firſt made an innovation in the world. "He treſpaſſed upon the rights of his brethren, and ſeized upon the land, which had been appropriated to God's future people." When the Iſraelites, therefore, were brought to Canaan, they came to their own inheritance, and thoſe who uſurped their property knew it, and knew by whom it had been appointed.

After all, we may obſerve, that the order to exterminate utterly in the caſe of the Canaanites, though expreſſed in *abſolute* terms, is ſuppoſed by ſome to have been *conditional* in fact; and that their lives were to have been ſpared upon their ſubmiſſion, and eſpecially upon their forſaking idolatry. Accordingly, it is plain in fact, that the Iſraelites either did not underſtand the command to be abſolute, or they knowingly tranſgreſſed it, even in the beſt and moſt flouriſhing ſtate of their affairs. To this purpoſe we have already remarked, that many of the Canaanites lived in ſubjection to the Iſraelites even to the times of their kings (1 Kings ix. 20, 21.); nor do we ever read that they were blamed for the favour they ſhewed them. Moreover, the reaſon and end for which the order for the extermination of the Canaanites was given, viz. leſt the children of Iſrael ſhould be enticed by them into idolatry, entirely ceaſed upon their ſubmiſſion, and abandoning their idol worſhip, which was generally the caſe. Beſides, it is pretty clearly inferred, that this order was conditional, from the circumſtance, that if the hearts of the Canaanites had not been hardened to oppoſe the Iſraelites, they would not have been cut off. Joſh. xi. 19, 20. Accordingly it has been alleged, that the ſeverity of the judgments inflicted upon the Canaanites for their extreme wickedneſs, of which the Iſraelites were the inſtruments, was not executed in the degree or to the extent which has been ſuppoſed. This has been maintained with great ſtrength of argument by learned and impartial judges; by Maimonides and others of the firſt account among the Jews, and alſo by many Chriſtians of our own and other countries. Grotius, in particular, on Deut. xx. 10. maintains, that the law, Exod. xxiii. 31, 32. and Deut. vii. 1, 2, was to be extended only to ſuch of theſe people as did not ſurrender themſelves on being ſummoned; as is evident from Joſhua xi. 19, 20. We ſhall further add, that idolatry, under the Jewiſh theocracy, was a crime of peculiar malignity: and therefore, although God has not thought fit to enact a general law obligatory on all mankind for puniſhing idolaters with death, and without his appointment it might not be executed; yet when it pleaſed him for wiſe ends to ſelect a particular nation, and among them to erect a peculiar ſacred polity, and to appoint that the worſhip of the one true God and of him only ſhould be the very baſis of their conſtitution, on which all their privileges, their national property, and their right to their country depended, it is evident, that under ſuch a conſtitution to revolt to idolatry and polytheiſm was in the moſt criminal ſenſe to be traitors to the community: and of courſe to arraign a law for inflicting a capital puniſhment upon idolaters under that particular conſtitution is highly abſurd. Nor ſhould it be forgotten, that the idolatry of the ancient Gentile world, and eſpecially that of the inhabitants of Canaan, was by no means a ſyſtem of merely ſpeculative *opinions;* but a courſe of the moſt atrocious and abominable *practices*, enjoining the cruel murder of numberleſs innocent children, as well as other human victims, and the moſt ſhocking lewdneſs, together with other vices of the moſt deteſtable nature. And ſurely it becomes a wiſe legiſlator and the moral Sovereign of the univerſe to reſtrain, by the moſt authoritative and awful ſanctions annexed to his laws, the commiſſion of ſuch deſtructive vices as theſe.

Mr. Wakefield, in his "Reply to the Second Part of the Age of Reaſon," by Thomas Paine, ſuggeſts, that ſome qualifications and ſoftenings in the caſe of many relations and occurrences in the ſcripture hiſtory, may be properly admitted, without any danger to the main fabric of revelation, upon the ground of exaggeration from national vanity, and the pride of individuals. Hence, he ſays, we may preſume upon enlargement in the part of the narrative on the ſplendour of their victories, the number of the ſlain, and the extent of their deſolations. He further intimates, that the Jewiſh hiſtorians had been accuſtomed to ſpeak of every tranſaction as preſcribed by the expreſs injunctions of Jehovah, when we are under no neceſſity, as he conceives, of ſuppoſing a ſpecific and actual interference in the caſe, but may very rationally, and in conformity to the rules of accepted interpretation, have recourſe for a ſolution to that predominant and univerſal perſuaſion, from their infancy, of the peculiar ſuperintendance of Jehovah, not only over the political welfare of their ſtate, but the private concerns of individuals. He adds, that it is a point worthy of inveſtigation how far Joſhua, and his fellow ſoldiers, in conformity to the ferocious character of the times, and the ſanguinary propenſities of military men, may actually have exceeded their commiſſion, and indulged themſelves in unauthorized acts of murder, rapine, and devaſtation. Having collected a variety of opinions on this intereſting ſubject, we muſt refer for a further diſcuſſion of it to the authors already cited, and to the following publications: Leland's Anſwer to Chriſtianity as old as the Creation, vol. ii. p. 429, &c. Leland's Deiſtical Writers, vol. ii. p. 446, &c. Prieſtley's Inſtitutes, vol. ii. p. 22, and Prieſtley's Notes on all the Books of Scripture, vol. i. Preface, Sermons, &c. by Joſeph Nicol Scot. vol. i. Lindſey's Converſations on the Divine Government, p. 80—85. Biſhop of Lincoln's Elements of Chriſtian Theology, vol. i. p. 70, &c.

CANACA, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the country of the Turdetani.

CANACE, in *Entomology*, an Indian ſpecies of PAPILIO, deſcribed by Linnæus, the wings of which are angulated and blue, with a pale band; beneath yellow, and green marbled. Amœn. Acad.

CANADA, ſometimes called the *Province of Quebec*, in *Geography*, a country of North America belonging to Great Britain, bounded on the north by Hudſon's bay, Eaſt Main and Labrador, on the eaſt by Labrador, the bay of St. Lawrence, and New Brunſwick, on the ſouth by the United States, and on the weſt by Lake Winnipeg and parts of America hitherto imperfectly deſcribed. It is computed to extend from the gulf of St. Lawrence and iſle of Anticoſti in the eaſt, to the lake of Winnipeg in the weſt, or from 64° to 97° W. long. 33 degrees, or about 2000 geographical miles, the breadth from the lake of Erie in the ſouth, or N. lat. 43°, may extend at leaſt to N. lat. 49°, comprehending 6 degrees, or 360 geographical miles. Others make its extent much more conſiderable towards the north, and eſtimate it at 500 miles. Its mean breadth is not above 200. It is now divided into two provinces, called Upper and Lower Canada; the former, which has been commonly denominated the Upper country, lies north of the Great Lakes, and is ſeparated from New York by the river St. Lawrence, here called the Cataraqui, and the lakes Ontario, and Erie. Its capital is Newark, or Niagara, on the Britiſh ſide of the Niagara; beſide which it has Kingſton, inhabited by emigrants from the United States, and reckoned by ſome the chief town. The latter lies on both ſides of the river St. Lawrence, and has for its capital Quebec, the chief city of the whole country. Upper and Lower Canada are ſeparated by the river Utawas, or more preciſely by a line, which commences at a ſtone boundary on the north bank of lake St. Francis in the river St. Lawrence at the cove, W. of Point-au-Boudet, and runs thence northerly to Utawas river, and to its ſource in lake Tomiſcaning, and thence due north till it ſtrikes the boundary of Hudſon bay, or New Britain. Upper Canada includes all the territory to the weſtward and ſouthward of the ſaid line, to the utmoſt extent of the country known by the name of Canada. The original population of this country conſiſted of ſeveral ſavage tribes, and it is ſaid to have been firſt diſcovered in 1497 by John and Sebaſtian Cabot. The French were the firſt Europeans who took poſſeſſion of it, and made their ſettlement at Quebec in 1608. In the year 1759 Quebec was captured by General Wolfe; and Canada was ceded to Great Britain by the treaty of Paris in 1763. From this period till the year 1774 the internal affairs of the province were regulated by the ordinance of the governor alone. In purſuance of the Quebec bill, which was then paſſed, a legiſlative council was appointed by his majeſty, and the number of its members was limited to twenty-three. But by an act paſſed by the Britiſh parliament in 1791, the executive power in each province was veſted in the governor; and a legiſlative council, and an aſſembly, were appointed for each of the provinces of Upper and Lower Canada, having power to make laws with the conſent of the governor; but the king may declare his diſſent at any time within two years after the bills are received, in which caſe they become void. The legiſlative council of Lower Canada conſiſts of 15 members; that of Upper Canada of ſeven. They are ſummoned by the governor under the king's authority, and appointed for life, unleſs they forfeit their office by an abſence of four years, or by ſwearing allegiance to any foreign power. The aſſembly of Lower Canada conſiſts of 50 members, and that of Upper Canada of 16; and they are choſen by the freeholders in the towns and diſtricts. The aſſembly is not to continue longer than four years, but it may be diſſolved ſooner; and the governor is bound to convene it at leaſt once in each year. The governor, together with ſuch of the executive council, as ſhall be appointed by the king for the affairs of each province, are to be a court of civil juriſdiction for hearing and determining appeals; ſubject, however, to ſuch appeals from their ſentence as heretofore exiſted. All lands in Upper Canada are to be granted hereafter in free and common ſocage; and alſo in Lower Canada, when the grantee ſhall deſire it, ſubject, nevertheleſs, to alterations by an act of the legiſlature; and the preſent ſyſtem of judicature in each province was eſtabliſhed by the Quebec bill of 1774. But whilſt the French laws were ſuffered by the Quebec bill to exiſt, in order to conciliate the affections of the French inhabitants, who were attached to them, although the abolition of theſe laws would be favourable to the intereſts of civil liberty; the criminal law of England was happily eſtabliſhed through every party of the country. The whole of Britiſh America, Canada included, is ſuperintended by an officer ſtyled governor-general of the four Britiſh provinces in North America, who, beſides other powers which he poſſeſſes, is commander in chief of all the Britiſh troops in the four provinces, and the governments attached to them, and Newfoundland. Each of the provinces has a lieutenant-governor, who, in the abſence of the governor-general, is inveſted with all the powers requiſite to a chief magiſtrate.

By an act paſſed in the 18th year of his preſent majeſty's reign, the Britiſh parliament has the power of making any regulations, that may be found expedient, reſpecting the commerce and navigation of the province, and alſo of impoſing import and export duties, reſtricted to the uſe of the province, and applied in ſuch a manner as the laws made in the council and aſſembly direct.

Every form of religion is completely tolerated in both provinces; but the Roman catholic religion is that of a great majority of the inhabitants; and by the Quebec bill of 1774, eccleſiaſtics of that perſuaſion are legally empowered to recover all the dues, which, before that period, they were accuſtomed to receive, as well as tithes, from the Roman catholic inhabitants; nevertheleſs, they cannot exact any dues or tithes from Proteſtants, or from lands held by Proteſtants; although ſuch lands might formerly have been ſubjected to dues and tithes for the ſupport of the Roman catholic church. Theſe dues and tithes are, however, ſtill to be paid to perſons appointed by the governor and reſerved in the hands of his majeſty's receiver-general, for the ſupport of the Proteſtant clergy actually reſiding in the province. By the act of the year 1791 it was alſo ordained, that the governor ſhould allot out of all lands belonging to the crown, granted after that period, one-ſeventh for the benefit of the Proteſtant clergy, to be ſolely applicable to their uſe; and it is required that all ſuch allotments ſhould be particularly ſpecified in every grant of waſte-lands; otherwiſe the grant is void. The governor, with the advice of the executive council, is authoriſed to conſtitute parſonages or rectories, and to endow them out of theſe appropriations, and to preſent incumbents to them, ordained according to the rites of the church of England. The clergy of this church, in both provinces, conſiſt at preſent only of 12 perſons, including the biſhop of Quebec; whereas thoſe of the church of Rome amount to 120, viz. a biſhop, three vicars-general, and 116 curates and miſſionaries, all of whom are reſident in the lower province, except five curates and miſſionaries. The number of the diſſenting clergy, in both provinces, is conſiderably ſmaller than that of the clergy of the church of England. The population of Upper Canada has been ſtated by ſome to amount to 40,000, by others to 20,000 Britiſh and French inhabitants, excluſive of 10,000 loyaliſts, who are ſettled in the upper parts of the province. Lower Canada, according to a cenſus, ordered to be taken by general Haldimand in 1784, contained 113,012 inhabitants. Both provinces may probably now contain more than 150,000 perſons; and their number is multiplying both by a natural increaſe and by emigrants from other countries. The number of ſavages has been eſtimated at 50,000. About nine-tenths of the inhabitants of theſe provinces are Roman catholics; and about five-ſixths of thoſe of Lower Canada are ſuppoſed to be of French extraction. Some of the lower claſſes of the French Canadians poſſeſs all the gaiety and vivacity of the people of France; but others have, to appearance, a great deal of that ſullenneſs and bluntneſs in their manners which is characteriſtic of the people of the United States: vanity, however, is the predominant feature in the character of all of them. Few of the men can read or write, and in this reſpect are much inferior to the women; but both men and women are ſunk in ignorance and ſuperſtition, and blindly devoted to their prieſts. The French language is univerſally uſed; Engliſh being reſtricted to the few Britiſh ſettlers. The houſes in Lower Canada are in general well furniſhed with beds, in the French ſtyle, very large, and raiſed four or five feet high. The houſes are for the moſt part built of logs; but they are much more compact and better conſtructed than thoſe of the United States; the logs being fitted more cloſely together, planed and white-waſhed externally, and generally lined with deal boards within. However, the inattention of the inhabitants to the admiſſion of air, by occaſionally opening their windows, renders them very diſagreeable and even unwholeſome. The expences of the civil liſt in this province are eſtimated at 20,000l. *per annum*, one-half of which is defrayed by Great Britain, and the other moiety by the province, out of the duties paid on the importation of certain articles, ſuch as ſpirits, wine, ſugar, molaſſes, coffee, tobacco, ſalt, and playing cards. The expence of the civil-liſt in Upper Canada is eſtimated at about a fourth of that of the lower province. The military eſtabliſhment in both provinces, together with the repairs of fortifications, &c. is computed to coſt Great Britain 100,000l. annually; and the like ſum is chargeable for preſents to the Indians, and ſalaries to officers employed among them in trade, &c. in Upper Canada. Theſe expences, however, are thought to be counterbalanced by the advantages of the commerce with this country, which is ſaid to employ about 7000 tons of ſhipping annually. The imports into Canada conſiſt of earthen-ware, hard-ware, and houſehold furniture, various articles of woollen, linen, and cotton, haberdaſhery, hoſiery, &c. ſtationary, leather, and its manufactures, grocery, wines, ſpirits, Weſt Indian produce, &c. &c. cordage of every deſcription, and the coarſe manufactures of iron. Some domeſtic manufactures of linen and of coarſe woollen cloths are carried on in moſt parts of Canada; but the greater part of theſe articles is ſupplied by Great Britain. The exports from Canada conſiſt of wheat, flour, biſcuit, timber, ſtaves, and lumber of various kinds, dried fiſh, oil, ginſeng, and various medicinal drugs, but principally of furs and peltries. The eaſtern part of Lower Canada, between Quebec and the gulf of St. Lawrence, is mountainous; and a few ſcattered mountains alſo occur between Quebec and the mouth of the river Utawas; but higher up the river St. Lawrence the face of the country is flat. The ſoil conſiſts principally of a looſe dark-coloured earth, 10 or 12 inches deep, lying on a bed of cold clay. This thin mould, however, is very fertile, and yields plentiful crops, although it is worked every year by the French Canadians, without being ever manured. The manure chiefly uſed, ſince the practice of manuring has been introduced, by thoſe who are the beſt farmers, is marle, which is found in great quantities in many places along the ſhores of the river St. Lawrence. The ſoil of Lower Canada is peculiarly adapted to the growth of ſmall grain. Tobacco alſo thrives well in it, but the culture is neglected, except for private uſe; and more than half of what is uſed is imported. The ſnuff produced from the Canadian tobacco is held in great eſtimation. Culinary vegetables arrive at great perfection in Canada, which is alſo the caſe with moſt of the European fruits. The currants, gooſeberries, and raſpberries are very fine: the latter are indigenous, and are found very abundantly in the woods. A kind of vine is alſo indigenous; but the grapes produced by it in its uncultivated ſtate are very poor and ſour, and not much larger than fine currants. In the foreſt there is a great variety of trees; ſuch as beech, oak, elm, aſh, pine, ſycamore, cheſnut, and walnut; and the ſugar maple-tree is found in almoſt every part of the country. Of this tree there are two kinds; the one called the ſwamp maple, being generally found on low lands, and the other, the mountain or curled maple, from its growing upon high dry ground, and from the grain of its wood being beautifully variegated with little ſtripes and curls. The former yields more ſap than the latter, but its ſap affords leſs ſugar. A pound of ſugar is frequently procured from two or three gallons of the ſap of the curled maple, whereas no more than the ſame quantity can be had from ſix or ſeven gallons of that of the ſwamp tree. The maple ſugar is the only ſort of raw ſugar uſed in the country parts of Canada, and it is alſo very generally uſed in the towns. See SUGAR.

The air of Lower Canada is very pure, and the climate uncommonly ſalubrious, except in the weſtern parts of the province, high up the river St. Lawrence. From Montreal downwards the climate very much reſembles that of the ſtates of New England. This difference of ſalubrity in the two parts of the province is aſcribed by Mr. Weld to the different aſpects of the country; to the eaſt, Lower Canada, like New England, is mountainous, but to the weſt it is an extended flat. According to his account, the extremes of heat and cold are amazing; Fahrenheit's thermometer, in the months of July and Auguſt, riſing to 96°, and yet in winter the mercury generally freezes. The tranſitions from heat to cold are leſs ſudden, and of courſe leſs injurious to the conſtitution in Canada than in the United States; and the ſeaſons are much more regular. The ſnow begins to fall in November; which is the moſt unpleaſant, cold, and gloomy part of the year: but in December the clouds are generally diſſolved, the froſt ſets in, and the ſky aſſumes a bright hue, continuing for weeks without a ſingle cloud. The greateſt degree of cold occurs in January, and it is ſometimes ſo intenſe, as to endanger a perſon, who is expoſed to it, being froſt-bitten; but the coldeſt days have intervals of warm weather. The winter in Canada is the ſeaſon of general amuſement; and the Canadians tranſport themſelves over the ſnow by means of their carioles and ſledges, each of which holds two perſons and a driver, and is uſually drawn by one horſe, with aſtoniſhing ſpeed as well as great pleaſure. With the ſame horſe, ſays Mr. Weld, it is poſſible to travel 80 miles in a day. The Canadians contrive to guard againſt the cold by ſeveral ſtoves placed in their halls, from which flues paſs to their different apartments, and by double windows and double doors to their houſes. When they go abroad, they cover the whole body with furs, except the eyes and noſe. In May the thaw comes on very ſuddenly, and in its progreſs, the ice in the river St. Lawrence burſts with the noiſe of a cannon, and paſſes towards the ſea with a tremendous rapidity and violence. As ſoon as the winter terminates, the rapid progreſs of vegetation is aſtoniſhing. Spring has ſcarcely appeared before it is ſucceeded by ſummer. In a few days the fields are clothed with the richeſt verdure, and the trees regain their foliage. The grain ſown in grain time in May affords a rich harveſt by the latter end of July. At this ſeaſon of the year, however, Fahrenheit's thermometer ſeldom riſes above 84°; in July and Auguſt it ſometimes riſes to 96°. The fall of the year is a moſt agreeable ſeaſon in Canada, as well as the ſummer. It is obſerved, that there is in general a difference of about three weeks in the length of the winter at Montreal and at Quebec; and of courſe in the other ſeaſons. When green peas, ſtrawberries, &c. were entirely gone at Montreal, they were in full ſeaſon at Quebec.

Mr. Weld, to whom we are indebted for a great part of this article, (ſee his Travels, vol. i.) has pointed out ſome inconveniences attending the tenures of land in Canada, which ought to be removed; more eſpecially as in ſuch a climate there is no occaſion for a barrier againſt colonization. The botany of Canada differs little from that of the United States; and the chief ſingularities in the zoology are the mooſe, the beaver, and ſome other animals deſcribed by Mr. Pennant in his arctic zoology. The reindeer appears in the northern parts, and the puma and lynx are not unknown. Both the Canadas are much infeſted with rattle-ſnakes. The humming bird is not uncommon at Quebec. The mineralogy is of little importance; and though iron ores have been diſcovered in various parts of the country, works for the ſmelting and manufacturing of it have been erected only at one place, in the neighbourhood of Trois Rivieres. The works are now the property of the Britiſh government. The bank of ore that ſupplies them is nearly exhauſted. We learn from Kalm (vol. ii. 349.) that there are lead mines which yield ſome ſilver; and it is probable that copper may be found, as it appears in the ſouth-weſt of Lake Superior. Coal has not yet been diſcovered in Canada. The country ſtill remains to be examined, and it is highly probable that important diſcoveries might be made. Its chief natural curioſities ſeem to be its rivers, lakes, and cataracts.

One of the moſt remarkable accidents which hiſtory records of this country, provided that it were ſatisfactorily aſcertained, is the earthquake of the year 1663, which is ſaid to have overwhelmed a chain of mountains of free-ſtone more than 300 miles long, and changed the immenſe tract into a plain. We ſhall enumerate and deſcribe the principal towns, lakes, rivers, and cataracts of this country in their proper places.

CANADA, *bay of*, lies on the eaſt ſide of the iſland of Newfoundland, between White and Hare bays, which laſt lies north of it.

CANADA *creeks* are three creeks of North America: one a water of Wood creek, which it meets four or five miles N. N.W. of Fort Stanwix, or New Fort Schuyler. The other two are northern branches of Mohawk river; the upper of which mingles its waters with the Mohawk in the townſhip of Herkemer, on the German flats, 16 miles below Old Fort Schuyler, and is croſſed by an ingeniouſly conſtructed bridge; the other empties into the Mohawk 13 miles below. Both theſe creeks are long, rapid, and unnavigable ſtreams, and ſupply the Mohawk with a conſiderable acceſſion of water. The lands adjoining them are rich and valuable, and furniſh inviting ſettlements.

CANADA, *ſea of*, or ſea of Huron, a name which might be given to the large inland ſea, that is formed by the lakes

Superior, Michigan, and Huron, and which is about 350 miles in length, and more than 100 at its greateſt breadth. See each of theſe articles.

Canada *Saga lake.* See Seneka *lake.*

CANADENSIS, in *Ornithology*, a ſpecies of Tetrao, that inhabits Hudſon's bay. The tail feathers are black, and at the tip tawny, and near the eyes are two white ſtripes. Gmel. This is ſuppoſed by late authors to be the male bird of the Linnæan Tetrao Canace, which is deſcribed as having the tail entire, with a white ſpot behind the ears and noſtrils. Syſt. Nat. edit. 12.

Canadensis, a ſpecies of Ardea, or Heron of the bald kind, diſtinguiſhed by the name of the brown crane of Canada among Engliſh authors. The forehead is naked and papillous; body cinereous; wings teſtaceous on the outſide. Gmel. Obſ. This is the brown and aſh-coloured crane of Edwards, *La Grue brune* of Buffon, and *La Grue de la Baye d'Hudſon* of Briſſon.

The length of this bird is three feet three inches. Bill three inches and three quarters long, of a duſky colour, with the tip of the upper mandible pale fleſh colour. The top of the head is covered with a red ſkin thinly beſet with hairs; cheeks and throat whitiſh; head and neck cinereous; upper part of the back, ſcapulars, and wing-coverts pale rufous margined with brown; breaſt, belly, thighs, and ſides aſh-coloured; tail deep aſh; legs and bare part of the thighs black. This bird is peculiar to America. It ſubſiſts on corn, and Indian maize occaſionally. Among the natives of North America it is known by the title of Samak-uchechauk.

CANAJOHARY, in *Geography*, a poſt-town of North America in Montgomery county, New York, ſeated on the ſouth ſide of Mohawk river, and comprehending a large diſtrict of fine country; 40 miles W. of Schenectady, and 56 miles from Albany. In the ſtate cenſus of 1796, 730 of the inhabitants appear to be electors. A creek of the ſame name enters the Mohawk in this town. This was the principal ſeat of the Mohawk Indians, and abounds with apple-trees of their planting, from which is made excellent cyder.

CANAKAMPALEAM, a town of Hindooſtan, in the Myſore country; 12 miles E. of Sattiemungulum.

CANAL, *Canalis*, in general, denotes a long, round, hollow inſtrument, through which a fluid matter may be conveyed.

In which ſenſe, it amounts to the ſame with what we otherwiſe call a pipe, tube, channel, &c. Thus the *canal* of an aqueduct, is the part through which the water paſſes; which, in the ancient edifices of this kind, is lined with a coat of maſtic of a peculiar compoſition.

Canal, a duct or pipe (as its derivation from the Latin *Canæ*, a cane, or reed, ſeems to imply), in which ſenſe it is uſed by anatomiſts in deſcribing the paſſage through which ſome of the animal fluids paſs: the term Canal has alſo been applied to denote any piece of water, eſpecially if of a conſiderable length in proportion to its width, and eſpecially ſuch as are ſtagnant, or have not the fall and natural motion which rivers have. Canals may be either for pleaſure or ornament, ſuch as are common in the vicinity of palaces and great houſes; or applied to the purpoſes of inland navigation. The artificial carriages for conveying ſtreams of water for the ſupply of cities or other purpoſes, as was done by the famous aqueducts of antiquity, and in modern times by the new rivers near London, and others, have ſometimes alſo been called Canals.

The importance and utility of canals have been ſo long and ſo generally acknowledged, that it is hardly neceſſary to introduce the ſubject with any obſervations to this purpoſe. Few perſons have more attentively conſidered or better underſtood the political and commercial intereſts of nations than the late Dr. Smith; and no one could be a more zealous advocate for the extenſion of inland navigation, as an effectual means of improving the country, in which it is encouraged. To this purpoſe he obſerves, in his "Wealth of Nations" (vol. i. p. 229.), that good roads, canals, and navigable rivers, by diminiſhing the expence of carriage, put the remote parts of the country more nearly upon a level with thoſe in the neighbourhood of large towns; and on that account they are the greateſt of all improvements. They encourage the cultivation of the remote parts, which muſt always be the moſt extenſive circle of the country. They are advantageous to towns, by breaking down the monopoly of the country in its neighbourhood; and they are advantageous to all parts of the country; for though they introduce ſome rival commodities into the old markets, they open many new markets to its produce. "It is not more than 50 years ago," ſays he in 1776, when the firſt edition of his work was printed, "that ſome of the countries in the neighbourhood of London, petitioned the parliament againſt the extenſion of the turnpike roads into the remoter counties. Thoſe remoter counties, they pretended, from the cheapneſs of labour, would be able to ſell their graſs and corn cheaper in the London market than themſelves, and would thereby reduce their rents, and ruin their cultivation. Their rents, however, have riſen, and their cultivation has been improved ſince that time." "All canals," ſays an intelligent writer on this ſubject (See Phillips's General Hiſtory of Inland Navigation, Introd.), "may be conſidered as ſo many roads of a certain kind, on which one horſe will draw as much as 30 horſes on ordinary turnpike roads, or on which one man alone will tranſport as many goods as three men; and 18 horſes uſually do on common roads. The public would be great gainers were they to lay out upon the making of every mile of a canal twenty times as much as they expend upon a mile of turnpike road; but a mile of canal is often made at a leſs expence than the mile of turnpike: conſequently there is a great inducement to multiply the number of canals."

The advantages reſulting from canals, as they open an eaſy and cheap communication between diſtant parts of a country, will be ultimately experienced by perſons of various deſcriptions: and more eſpecially by the manufacturer, the occupier or owner of land, and the merchant. The manufacturer will thus be enabled to collect his materials, his fuel, and the means of ſubſiſtence, from remote diſtricts, with leſs labour and expence; and to convey his goods to a profitable market. As canals multiply, old manufactures revive and flouriſh, new ones are eſtabliſhed, and the adjoining country is rendered populous and productive. To the occupier of land, canals are uſeful in a variety of ways. In ſome caſes, they ſerve the purpoſes of draining and of irrigation; in others, they furniſh manure at a cheap rate; and they facilitate the conveyance of the produce to places where it may be diſpoſed of to the greateſt advantage. The landowner muſt of courſe be benefited, by the increaſing value and advanced rent of his eſtate, in conſequence of the improvement it receives from the induſtry of the occupier, excited and encouraged by an immediate recompence. The wholeſale trader and merchant are likewiſe enabled to extend their commerce by means of canals; as they can thus export greater quantities and varieties of goods from places remote from the ſea, and eaſily ſupply a wider extent of inland country with the commodities that are imported from foreign nations. Nor are they merely the means of extending and increaſing foreign commerce, but they ſerve alſo to create and augment an internal trade, which, with all the advantages attendant on foreign commerce, may probably far exceed it in extent, value, and importance. We might add, that an inland communication between parts of a country, at a great diſtance from one another, contribute to the ſecurity, as well as to the extenſion of commerce, in the boiſterous months of winter, and in times of war, when the navigation of the ſeas would be attended with danger. "Were we to make the ſuppoſition of two ſtates," ſays Mr. Phillips (ubi ſuprà), "the one having all its cities, towns, and villages upon navigable rivers and canals that have an eaſy communication with each other; the other poſſeſſing the common conveyance of land-carriage; and ſuppoſing, at the ſame time, both ſtates to be equal as to ſoil, climate, and induſtry; commodities and manufactures, in the former ſtate, might be exported 30 *per cent.* cheaper than in the latter; or, in other words, the firſt ſtate would be a third richer and more affluent than the ſecond." Should it be objected, that navigable canals waſte or occupy too great a portion of land in the countries through which they paſs, the objection may be obviated by the conſideration, that one mile of a canal, 14 yards wide, takes up little more than five acres of land.

If we advert to fact, and conſult the records of hiſtory with regard to the ſtate of different nations, we ſhall find, that civilization and commerce have very much depended on the facility with which the inhabitants of remote diſtricts have maintained intercourſe with one another, as well as with diſtant countries. As the ocean ſerves to connect diſtant countries, navigable rivers and canals unite the different provinces and diſtricts of the ſame country; and as navigation, by means of the ocean, produces an intercourſe and mutual exchange of productions between different kingdoms, inland navigation, in like manner, facilitates a communication between different parts of the ſame kingdom, and conſequently promotes trade and induſtry. In North America, the plantations have conſtantly followed either the ſea-coaſt or the banks of the navigable rivers, and have ſcarcely any where extended themſelves to any conſiderable diſtance from the one or the other. The nations that appear to have been firſt civilized, were thoſe that dwelt round the coaſt of the Mediterranean ſea, which, from a variety of circumſtances, was extremely favourable to the early navigation of the world. Of all the countries on the coaſt of the Mediterranean, Egypt ſeems to have been the firſt, in which either agriculture or manufactures were cultivated and improved to any conſiderable degree. Upper Egypt extends itſelf nowhere above a few miles from the Nile, and in Lower Egypt that great river breaks itſelf into many different canals, which, aided by a ſmall degree of art, ſeem to have afforded a communication by water-carriage, not only between all the large towns, but between all the conſiderable villages, and even to many farm-houſes in the country; nearly in the ſame manner as the Rhine and the Maeſe do in Holland at preſent. The extent or facility of this inland navigation was probably one of the principal cauſes of the early improvement of Egypt. The improvement in agriculture and manufactures ſeems likewiſe to have been of very great antiquity in the provinces of Bengal in the Eaſt Indies, and in ſome of the eaſtern provinces of China. In Bengal, the Ganges and ſeveral other large rivers form a great number of navigable canals, in the ſame manner as the Nile does in Egypt. The caſe is the ſame in the eaſtern provinces of China, where ſeveral large rivers form, by their different branches, a multitude of canals, and by communicating with one another afford an inland navigation much more extenſive than that either of the Nile or the Ganges, or perhaps of both of them united. It is remarkable, however, that neither the ancient Egyptians, nor the Indians, nor the Chineſe, encouraged foreign commerce; but they all ſeem to have derived their extraordinary opulence from this inland navigation. On the other hand, thoſe nations that have been deſtitute of the means of inland navigation, either by rivers or canals, have remained from one age to the other in the ſame barbarous and uncivilized ſtate. This obſervation is exemplified in the ſtate of all the inland parts of Africa, and of that part of Aſia which lies at any conſiderable diſtance north of the Euxine and Caſpian ſea, the ancient Scythia, and the modern Tartary and Siberia. The commerce that may be carried on by means of a river, which does not break itſelf into any great number of branches or canals, and which runs into another territory before it reaches the ſea, can never be very conſiderable; becauſe it is always in the power of the nation who poſſeſſes that other territory to obſtruct the communication between the upper country and the ſea. Thus the navigation of the Danube is of very little uſe to the different ſtates of Bavaria, Auſtria, and Hungary, in compariſon of what it would be if any of them poſſeſſed the whole of its courſe till it falls into the Black Sea. To theſe general obſervations, we ſhall ſubjoin a brief account of the principal canals that have been formed among the nations of antiquity, and among foreign nations in later times; reſerving the principal part of this article for an enumeration of the canals of our own country, and for an illuſtration of the principles on which they are conſtructed, the regulations to which they are ſubject, and the various uſes to which they are applied.

In the hiſtory of ancient nations we diſcover various traces of canals, formed for military, agricultural, commercial, or other purpoſes. The "foſſiones Philiſtinæ" of Pliny (l. iii. c. 16.), which were large canals at the mouth of the Eridanus in Liguria, are aſcribed by Mr. Bryant to the Canaanites, and particularly to the Caphtorim, who at a remote period migrated from Philiſtim; and hence theſe outlets of the river were named "Philiſtinæ." We learn from Herodotus (l. i. c. 174.) that the Cnidians, a people of Caria in Aſia Minor, formed a deſign of digging a channel through the iſthmus which joined their territory to the continent; but they relinquiſhed the undertaking, becauſe they were interdicted by an oracle. Strabo informs us (l. ix. p. 406, &c.). that canals and pits were dug in Bœotia, at a very remote period of antiquity, for drawing off the water of the lake Copais, which would otherwiſe have overflowed the whole country. This lake near the ſea terminates in three bays, which advance to the foot of mount Ptous, ſituate between the ſea and the lake. From the bottom of each of theſe bays numerous canals were made to diverge and traverſe the mountain through its whole breadth, ſome of which were more than a league in length, and others of a much greater extent. For the purpoſe of excavating or of cleanſing them, very deep wells had been ſunk at ſtated diſtances on the mountain. The labour of forming and the expence of maintaining theſe canals muſt have been immenſe. They have ſince been almoſt wholly neglected, ſo that moſt of them are choaked up, and the lake ſeems to be gaining on the plain. The inhabitants of Babylonia or Chaldæa guarded againſt the detrimental inundations of the Tigris and Euphrates by a great number of artificial rivers and canals, which ſerved to diſtribute the waters, to benefit the country in general, and to effect an eaſy communication and intercourſe between the occupiers of different parts of the country. The Euphrates, according to Ptolemy (l. v. c. 17.), above Babylon, near a town in Meſopotamia, called Sipphara, divides itſelf into two branches, one running to Babylon, and the other to Seleucia, where it falls into the Tigris. The latter, ſays Pliny (l. vi. c. 26.), was partly artificial; and he places Seleucia at the confluence of the Tigris and Euphrates, adding that the Euphrates was conveyed to it by a canal. Prideaux, (Conn. b. ii. part i. p. 103.) on his authority, ſuppoſes that branch to have been artificial, and aſcribes it to Nebuchadnezzar. Between theſe two branches an artificial canal was cut from the Euphrates, above Babylon, to the Tigris at Apamea, 60 miles below Seleucia. This canal, which was large and navigable, was called *Naarmalcha*, which ſee. From the Naarmalcha the emperors Trajan and Severus, in their wars with the Parthians, dug a new canal to the Tigris, near Coche on the weſt, and Cteſiphon on the eaſt ſide of that river. At the diſtance of 800 furlongs from Babylon, to the ſouth was another canal, called by Arrian (Exped. Alex. l. vii.) Pallacopas, and by Appian (Bell. Civil. l. ii.) Pallacotta, derived from the branch of the Euphrates that paſſed through Babylon and conveyed water to certain lakes or marſhes in Chaldæa. On this canal, or river, as Arrian calls it, Alexander ſailed from the Euphrates to theſe lakes. Strabo (l. xvi.) deſcribes the courſe of this canal, without naming it. But it is impoſſible to trace out, with accuracy, theſe and the other numerous branches and canals which watered the ancient country of *Babylon*, which ſee. Many of thoſe that were formerly conſiderable are now loſt; and others have been formed ſince, that did not exiſt in ancient times; for a country ſo much watered, ſo low in ſituation, and ſo ſubject to the violence of extraordinary inundations from the two large rivers, the Tigris and Euphrates, and ſo neglected as it has been for ſeveral ages, muſt have often and very conſiderably changed its face ſince the time of Ptolemy; and it is almoſt impoſſible to deſcribe it ſuch as it was while it continued to be the ſeat of empire, when the inhabitants were rich enough to take care of its numerous banks, and to keep them in repair. See BABYLONIA.

Both the Greeks and Romans propoſed to make a canal acroſs the iſthmus of Corinth, which joins the Morea and Achaia, and thus to make a navigable paſſage by the Ionian ſea into the Archipelago. Demetrius Poliorcetes, Julius Cæſar, Nero, and Caligula renewed the attempt, but without ſucceſs. Plin. l. iv. c. 4. After the death of Alexander the Great, Seleucus Nicanor attempted to make a canal between the Euxine and Caſpian ſeas, but his undertaking proved abortive. Travellers, however, aſſert that traces of very deep vallies are to be ſeen, through which the canal is ſaid to have paſſed. Selim II. and Peter the Great, renewed the attempt, but they were prevented from ſucceeding, not ſo much by the impracticability of the ſcheme as by other collateral circumſtances. The Romans, more intent on conqueſts than on commerce and the arts, afford us few inſtances of canals for internal navigation. We find, however, that Druſus, under the emperor Auguſtus, having conceived the deſign of marching into Germany without haraſſing his troops by a long and difficult march, facilitated the execution of it by making a canal that communicates from the Rhine with the Iſſel, extending from the village of Iſeloort to Doeſbourg. This canal received a great part of the waters of the right branch of the Rhine, which became by that means much leſs conſiderable. At the ſame time he opened a third mouth from that river into the ſea, mentioned by Pliny under the name of "Flevum Oſtium." But the face of the country has been much altered from that time. Lucius Verus who commanded the Roman army in Gaul under Nero, attempted to make a canal between the Moſelle and the Rhine. Corbulo under Claudius employed his ſoldiers in digging a canal between the Rhine and the Maeſe, through an interval of about 23 miles, in order to preſerve the country from inundations, and to ſerve as a drain, in caſe of any extraordinary overflowings of the ſea. Cluverius and Cellarius ſuppoſe this to be the canal that begins at Leyden, paſſes by Delft, continues on to Maeſland, and joins the Maeſe at the village of Sluys. Claudius alſo employed 30,000 men for about 11 years in digging a canal through a mountain for draining the lake Fucinus (now Celano) into the river Liris; and in 1789 this canal was begun to be cleanſed to the great relief of the neighbouring country, which was inundated by its obſtruction. The Romans, during their reſidence in this country, made a canal between the Nyne, a little below Peterborough, and the Witham, 3 miles below Lincoln, called by the modern inhabitants "Caerdike," which is now almoſt wholly filled up. It was almoſt 40 miles long, and, as far as we may judge from the ruins, very broad and deep. Some have ſuppoſed it to be a Daniſh work. J. Morton ſuppoſes it to have been made under the emperor Domitian. Urns and medals have been diſcovered on the banks of this canal, which ſeem to confirm that opinion. Morton's Hiſt. Northamptonſhire, ch. 10. Charlemagne, at a later period, formed a deſign of joining the Rhine and the Danube, and of thus making a communication between the ocean and the Black ſea, by a canal extending from the river Almutz, which diſcharges itſelf into the Danube, to the Reditz, which falls into the Maine; and the Maine joins the Rhine near Mayence. In the execution of this deſign he employed a great number of workmen, but he was prevented from completing it by a variety of obſtructions which occurred. Of all the countries to which ancient hiſtory directs our attention, Egypt was the moſt diſtinguiſhed by its numerous canals, which, according to Savary, amounted to 80, ſeveral of which are 20, 30, and 40 leagues in length. Theſe ſerved to receive and diſtribute the waters of the Nile, at the time of its inundation. Moſt of theſe are neglected, and, conſequently, one-half of Egypt deprived of the means of its cultivation. The canals which convey the water to Cairo, to the province of Faioum, and to Alexandria, ſeemed to have engaged the chief attention of government. "An officer," ſays baron De Tott (Memoirs, vol. ii. p. 21, &c. Eng. ed.) "is appointed to watch this laſt, and hinder the Arabs of Bachria, who receive the ſuperfluous waters of this canal, from turning them off before Alexandria be provided, or opening it before the time fixed, which would hinder the increaſe of the Nile. That which conveys the waters into Faioum is watched in like manner, and cannot be opened before that of Cairo, which is called the canal of Trajan." But the principal of theſe works was the Grand Canal, by which a communication was made between the Nile and the Red ſea. This was begun, according to Herodotus (lib. ii. p. 181, &c. ed. Weſſelingii.) by Necos, the ſon of Pſammitichus, who deſiſted from the attempt on an anſwer from the oracle, after having loſt 120,000 men in the enterpriſe. Strabo (lib. xvii. p. 1157. ed. Caſaubon.) aſcribes the commencement of it to Seſoſtris, before the Trojan war. It was reſumed and carried on by Darius, ſon of Hyſtaſpes, who relinquiſhed the work on the repreſentation made to him by unſkilful engineers, that the Red ſea being higher than the land of Egypt, would overwhelm and drown the whole country. Diodorus Siculus (lib. i. p. 39. ed. Weſſelingii.) gives the following account of this canal, "A canal of communication has been cut, which paſſes from the gulf of Peluſium to the Red Sea. It was begun by

Necos, the ſon of Pſammitichus, and continued by Darius king of Perſia; but left imperfect in conſequence of the advice of ſome perſons who aſſerted that it would lay Egypt under water, becauſe the land was below the level of the Red ſea. Ptolemy II., however, finiſhed the undertaking, and conſtructed, in the moſt convenient part of the canal, a dam, or ſluice, ingeniouſly contrived, which opened to give paſſage, and immediately cloſed again. Hence the river which diſcharges itſelf into the ſea, near the city of Arſinoe, has received the name of Ptolemy." From this paſſage, ſays baron De Tott, it is plain, that the ſluices ſtill exiſted in the time of Diodorus. The entrance of the canal near Suez yet remains, and might eaſily be rendered navigable, without employing ſluices or locks, as the difference of the level is very ſmall, and without endangering Egypt with inundations. This part of the iſthmus, ſays the baron, affords land very favourable for ſuch an excavation, through the ſmall interval of 12 leagues, which ſeparates the Arabian gulf from the arm of the Nile which approaches it, and afterwards falls into the Mediterranean at Tineh. Strabo adds (ubi ſupra) that this canal was afterwards cleanſed by Trajan. Its width, being 100 cubits, of 22 inches to a cubit, was ſufficient for admitting the paſſage of two galleys abreaſt; and its depth was ſuch as to bear the largeſt veſſels. Pliny, in his account of this canal, (lib. vi. cap. 29.), ſtates its breadth at 100 feet, its depth at 40, and its length to the bitter fountains (near Arſinoe) at 37 miles. By means of this canal, the valuable commodities of India, Perſia, Arabia, and the kingdoms on the coaſt of Africa, which were brought by ſhipping to the Red ſea, were conveyed to the Nile; and thence diſtributed by the Mediterranean not only to Greece and Rome, but to all the ſurrounding nations, until the Portugueſe diſcovered a paſſage to India by the Cape of Good Hope. It did not, however, long ſerve the uſeful purpoſes of commerce, which were at firſt expected. Merchants were diſſatisfied with the delay occaſioned by going to the very bottom of the gulf, and afterwards with the inland navigation of the canal, and that of the Nile, to Alexandria. They found it much more expeditious to unload at Berenice, near the coaſt of the Red ſea (ſee BERENICE): and after three days' journey, to ſend their merchandiſe directly down to Alexandria. Accordingly, this canal was diſuſed, and goods were conveyed from Berenice to the Nile by land; a mode of conveyance occaſionally uſed at this day. Strabo and others have aſſerted, that this canal was again opened about the year 635, by Amru, governor or prefect of Egypt, under the caliph Omar, for the conveyance of the corn of Egypt to Arabia, which was then grievouſly diſtreſſed by a famine. Elmacin, or Al Makin, ſays, that a new canal was opened for this purpoſe, and called by Amru the river of the emperor of the faithful; but it has been more generally ſuppoſed, that he only renewed the ancient canal, the navigation of which, towards the decline of the Roman empire, had been much neglected. The authors of the Modern Univerſal Hiſtory (vol. i. p. 333.), diſcredit the relation of Elmacin and Eutychius; and allege that there never was any paſſage for veſſels dug between the towns of Al Foſtat, on the eaſtern bank of the Nile, and Al Kolzom or Colzum on the Red ſea. The river, or rivulet, denominated by them the river of the emperor of the faithful, ſay theſe authors, was undoubtedly no other than the Amnis Trajanus of Ptolemy, or the Khalig, which annually ſupplies the city of Cairo, as well as the neighbouring country with water. For the preſent ſtate of this canal, ſee CAIRO. They ſuppoſe, therefore, that, on the occaſion now referred to, the caliph Omar ordered Amru to make the Khalig more navigable, by clearing it of the gravel or ſand with which it was then choaked up; and that, for this reaſon, it received the name of the river of the emperor of the faithful. Elmacin farther informs us, that the Alexandrian canal was ſtopped again, at the end next the Red ſea, by the caliph Abu Jaafar, or Almanſor, in the year of the Hegira 150, A.D. 767. Some traces of this canal are ſtill ſubſiſting; and M. Boutier, in 1703, diſcovered that end of it, which riſes out of the moſt eaſterly branch of the Nile. Hiſt. Acad. Sc. for 1703, p. 110, &c.

The canal of Alexandria, cut from the Nile to this city by Ptolemy, during the inundation of the Nile, receives its water at Latf, oppoſite to Fouah, and has three bridges over it, of modern conſtruction. Near the former, by the ſea-ſide, is the entrance of the ſubterraneous aqueduct, that carries a ſupply of water for the Alexandrians into the ciſterns, the arches of which ſupported the whole extent of the ancient city, but they are now incapable of being traced out. The mouth of this aqueduct is now blocked up; but when the water of the canal had arrived to a certain height, in conſequence of the riſe of the river, the principal magiſtrates of the city went in great ceremony to break down the dam. When the ciſterns were full, it was again built up, and the water of the canal continued to fall into the ſea at the old port. It was by this eaſy communication that merchandiſe was formerly conveyed through Egypt. The dangerous paſſage of the mouth of the Nile was thus avoided, as well as the perils of the ſea. But beſide furniſhing the city with water, and facilitating its commerce, this canal, which paſſed along the upper part of the cultivated lands, on the left hand of the Nile, contributed very much to their fertility. In proceſs of time it was ſhamefully neglected. However, it was cleanſed by order of Bonaparte, in his irruption into Egypt, as far as Rhamania. See ALEXANDRIA.

Egypt is interſected in various directions by many other canals. Several of them iſſue from that arm of the Nile which runs to Damietta, and contribute to fertilize the province of Sharkia, which, making part of the iſthmus of Suez, is the moſt conſiderable of Egypt, and the moſt capable of a great increaſe of cultivation. Others run through the Delta, and of theſe, ſays baron De Tott, many are navigable. The canal of Menouf communicates with the two branches of the Nile, 10 leagues below the angular point, called the "Belly of the cow." See MENOUF. The canal of Bahira proceeded from the lake Mareotis, near Alexandria, and having ſent off branches which joined the weſtern branch of the Nile at Eſhlim, Shabur, and Nadir, paſſed on to Upper Egypt. The other principal canals of Egypt will be mentioned in connection with the towns or diſtricts to which they belong.

There is no country on the face of the globe that abounds more with canals and navigable rivers than CHINA: to which article we ſhall refer an account of its inland navigation. Hindooſtan likewiſe furniſhes inſtances at a remote period of the acknowledged importance and utility of canals. As the country between Delhi and the Panjab was ſcantily ſupplied with water, the emperor Feroſe III., who died in 1388, undertook, ſays major Rennell (Memoir, p. 71.), the noble, as well as uſeful, taſk of ſupplying it better, and at the ſame time of applying the water, ſo furniſhed, to the purpoſes of navigation.

The immediate object of the canals, projected and executed by Feroſe, for an account of which we refer to Rennell (ubi ſupra) ſeems to have been the junction of the Setlege and Jumnah rivers, through an interval of 240 geographical miles, and remotely that of the Indus and Ganges. If this grand deſign of Feroſe had been completed, it muſt have ranked with the greateſt works of this kind; "for we ſhould then have ſeen two capital rivers, which traverſe a large part of Southern Aſia, which enter the ſea at the diſtance of 1500 Britiſh miles aſunder, and which ſtretch out their arms, as it were, to meet each other, united by art: and thoſe by nature to a third; ſo as to form an uninterrupted inland navigation from the frontiers of China to thoſe of Perſia." The country of Bengal is ſo interſected in various directions by the natural canals of the Ganges and Burrampooter rivers, together with their numerous branches, as to form the moſt complete and eaſy navigation that can be conceived: and it is ſuppoſed, that this inland navigation furniſhes conſtant employment for 30,000 boatmen, who are employed in conveying by water through the kingdom of Bengal and its dependencies, all the ſalt and a large proportion of the food conſumed by 10,000,000 people, and in tranſporting commercial exports and imports, probably to the amount of 2,000,000*l.* ſterling per annum.

The improvement of inland navigation engaged but little attention in Ruſſia before the reign of Peter the Great. With him, after his return from Holland, where he had obſerved its uſeful effects, the conſtruction of canals became a principal object. Of thoſe projected and haſtily executed by him, we may mention that of Cronſtadt, that of Ladoga, that of Viſhnei-Voloſhok, and that for forming a communication between Moſcow and the Don. For an account of the canal of Cronſtadt, which was left unfiniſhed by czar Peter, ſee Cronstadt. The Ladoga canal was begun in 1718 by his order, and finiſhed during the reign of the empreſs Anne. It was carried out firſt only as far as the Kabona, a rivulet which enters the lake to the eaſt of Schluſſelburgh; but now reaches, without interruption, from the Volkof to the Neva. The length is 67½ miles, and its breadth 70 feet; the mean depth of water in ſummer is ſeven, and in ſpring ten feet; it is ſupplied by the Volkof and eight rivulets. The barks enter through the ſluices of the Volkof, and go out through thoſe of Schluſſelburg. In 1778, four thouſand nine hundred and twenty ſeven veſſels paſſed through this canal. A ſcheme has been projected, and in part executed, for uniting the White Sea and the Baltic, and thus improving the commerce between Archangel and Peterſburgh, by forming a communication between the Ladoga and Beilo-Ozero to the Duna. The canal of Viſhnei-Voloſhok, forms a communication by water between Aſtracan and Peterſburgh, or between the Caſpian and the Baltic. This canal was begun and completed under Peter the Great; but it has been conſiderably improved by the empreſs Catharine, ſo that veſſels reach Peterſburgh in half the time which they formerly employed. In order to form an idea of the courſe of this inland navigation, a map of Ruſſia ſhould be conſulted; and it will be ſeen, that the river Shlina forms the lake Maſtino, which gives riſe to the Maſta; this, after a courſe of 234 miles falls into the lake Ilmen, from which iſſues the Volkof; and this, running 130 miles to the lake Ladoga, ſupplies the Neva; ſo that, in effect, the Shlina, the Maſta, the Volkof, and the Neva, may be conſidered as the ſame river flowing into and through different lakes. By uniting, therefore, the Shlina, which communicates with the Baltic, with the Tvertza, which flows by the Volga into the Caſpian, the canal of Viſhnei-Voloſhok completes the communication between theſe two ſeas. In autumn the navigation from Viſhnei-Voloſhok to Peterſburgh is performed in little more than a month; in ſummer in three weeks. In one year 3485 barks have paſſed through this canal.

The grand project of uniting the Caſpian and the Baltic with the Black Sea, by the junction of the Don and Volga, was planned by Peter the Great. Theſe two rivers approach each other within the diſtance of 40 miles in the province of Aſtracan; and two rivulets, the Hoſla which falls into the Don, and the Camaſhinſka falling into the Volga, are ſeparated only by an interval of five miles. If theſe rivulets could be made navigable, and united by a canal, the Black Sea would be joined with the Caſpian and Baltic. Repeated attempts have been made for this purpoſe, but they have hitherto failed. However, as the Volga and the Don are but 40 miles diſtant, and land carriage in this country is very cheap and eaſy, the advantages reſulting from the projected canal would be ſcarcely equivalent to the expence of forming it. In 1802, a beautiful chart was publiſhed, exhibiting a view of all the canals in Ruſſia, that have been formed between the White and Black Sea, and between the Baltic and the Caſpian. The inland navigation is already carried through ſuch an extent in Ruſſia, that it is poſſible to convey goods by water 4472 miles from the frontiers of China to Peterſburgh, with an interruption only of about 60 miles; and from Aſtracan through a tract of 1434 miles. Cox's Travels in Poland, Ruſſia, &c. vol. iii. Tooke's view of the Ruſſian Empire, vol. i.

The firſt ſovereign of Sweden, who duly appreciated the utility of inland navigation, was Guſtavus Vaſa. Having made Lodeſe (now Gotheborg) a ſtaple-town of trade, he conceived hopes, that in order to prevent the merchant-ſhips bound to Sweden from being obliged to ſail through the Sound, the merchandize might, at ſome future period, be tranſported from thence to Stockholm, by means of the Wenner, Hielmar, and Mæler, when the rivers and lakes uniting with them ſhould be rendered navigable. Eric XIV. deſirous of executing his father's plans, directed a ſurvey to be made of the waters communicating with thoſe lakes, and plans to be formed for joining them by artificial canals. But the turbulence and misfortunes of his reign fruſtrated the accompliſhment of his deſigns. The ſame object was kept in view by ſucceeding ſovereigns. Charles IX. promoted it by the Carlſgraf canal, and Charles XI. by that of Arboga. Guſtavus Adolphus wiſhed to encourage the deſign, but could not find perſons competently qualified to execute it: and Charles XI. was diſcouraged by the report of Dutch engineers, who declared it impracticable. Charles XII. however, approved the propoſal of the celebrated engineer, Polhem, for rendering the cataracts of Trolhætta navigable, and for opening a communication, not only between Gotheborg and Stockholm, but alſo with the Wenner, the Vetter, and Nordkioping, ſufficient for the paſſage of large veſſels. The execution of this plan was immediately begun by his order, and, after his death, revived by Adolphus Frederic. It comprehended three principal parts; viz. the junction of the Mæler and the Hielmar, of the Hielmar and Wenner, and of the Wenner with the German Ocean. The two lakes of the Mæler and Hielmar are united by the Ulviſon, and the canal of Arboga. This canal (ſee Arboga) is, for the moſt part, of ſufficient breadth to receive two barks a-breaſt, and its loweſt depth is eight Swediſh feet. It is chiefly ſupplied with water from the lake Hielmar, which is 80 feet higher than its level; and this fall is broken by eight ſluices. With a view of joining the Hielmar and Wenner, many ſchemes were propoſed, but difficulties occurred which prevented the completion of them. The junction of the Wenner with the German Ocean has been attempted by the Carlſgraf canal, the canal of Trolhætta, and the ſluices of Akerſtræm and Edet. The Carlſgraf canal, ſo called from Charles IX. who commenced it, connects the Wenner with that part of the Gotha, where it is firſt navigable. In 1768 a new ſluice to ſupply the place of that of Polhem, carried away by the water, and of that called Teſſin, found inſufficient, was completed ; and denominated the ſluice of Guſtavus. This ſuperb work is a cut of 400 feet, partly perforated through the ſolid rocks, and conſiſting of two locks, each 200 feet long, and 36 broad ; the ſides being ſtrongly faced with brick and ſtone. The greateſt depth of water is 13, and the loweſt ſix feet. This canal is commonly navigated by veſſels of 80 tons burden. From the end of this canal to the village of Trolhætta, including an interval of five miles, the navigation of the Gotha is uninterrupted ; but when it burſts at once into the cataracts of Trolhætta, called the "gulfs of hell," all farther navigation becomes impracticable through a ſpace of about two miles. Here it is divided into four principal cataracts, ſeparated by whirlpools and eddies, and deſcending through a perpendicular height of 100 feet. Nevertheleſs, an attempt has been made to form a canal through theſe cataracts. The firſt attempt, after much labour and expence, failed ; and another plan was adopted. The length of the canal was to be 4700 feet, its breadth 36, and its depth in ſome parts above 50 ; and it was to conſiſt of nine ſluices ; but the whole of the cut was to be excavated through a bed of red granite ; and though it ſhould not be condemned as impracticable, the difficulties attending it appear to be almoſt inſuperable. After all, it has been doubted, whether the enormous expence attending the execution of it will be compenſated by the advantages reſulting from its completion. Guſtavus III., ſoon after his acceſſion, viſited the works, and ordered all of them to be ſuſpended, except the ſluices of Guſtavus and Aker. But, in order to facilitate the conveyance of merchandiſe from the diſtricts bordering on the Wenner to Gotheborg, a wooden road has been conſtructed on the ſide of the river, from the beginning to the end of the cataracts. About a mile below the cataracts, the courſe of the Gotha is again interrupted by a fall, called Akerſtræm ; and here a canal has been made through a rock, 182 feet long, including the ſluice, 26 deep, and 36 broad. From Akerſtræm the river is clear to Gotheborg, excepting at Edet, where it is intercepted by a bed of rocks. On one ſide of theſe rocks another cut has been made, 600 feet long, 20 deep, and 18 broad. The iron and other merchandiſe are now tranſported acroſs the lake to Wennerſborg, through the Carlſgraf canal, and down the river Gotha to Trolhætta. At the cataracts they are unloaded, carried over the wooden road two miles to the end of the falls, again embarked, and paſſing through the Akerſtræm and Edet ſluices, arrive without further impediment at Gotheborg. Coxe's Travels, vol. iv.

The principal canal of Denmark is that of Kiel. This canal was deſigned to complete the inland navigation, which, for the purpoſe of facilitating the communication between the Baltic and the German Ocean, is formed acroſs the duchy of Holſtein, and it unites with the river Eyder, which paſſes by Rendſburgh, and falls into the German Ocean at Tonningen. It begins about three miles N. of Kiel, at the mouth of the river Lewenſawe, which heretofore ſeparated Holſtein from Sleſwic, and will become a new boundary between theſe two duchies. The diſtance from its beginning to the eaſt ſluice at Rendſburgh is 27 Engliſh miles ; but as the Eyder is navigable about 6¾ miles above Rendſburgh, the cut neceſſary for completing the communication between the two ſeas is only 20½ miles. It was begun in 1777, and was opened in 1785. The perpendicular fall towards the Baltic is 25 feet ſix inches ; that towards the ocean 23 ; and the veſſels will be raiſed or let down by means of ſix ſluices. The breadth of the cut is 100 feet at the top, and 54 at the bottom ; the ſluices are 27 feet broad and 100 feet long, and the loweſt depth of water is 10 feet. Merchantmen of about 120 tons burden will be able to navigate this canal. The utility of this important undertaking is indiſputable. At preſent, even the ſmalleſt veſſels, trading from any part of the Daniſh dominions in the Baltic to the Northern Sea, muſt make a circuit round the extremity of Jutland, and are liable to be detained by contrary winds. This navigation is ſo tedious, that goods ſhipped at Copenhagen for Hamburgh are not unuſually ſent by ſea only to Lubec, and from thence by land. The object, ſays Mr. Coxe, of thoſe who planned this canal, was to draw by Kiel into the Baltic, the commerce of Bremen, Hanover, and Weſtphalia, which is now carried down the Weſer, and by Gluckſtadt upon the Elbe, to Hamburgh and Lubec ; and to facilitate the tranſport of merchandiſe from Holland and the North Sea to the ports of the Baltic. But the difficult navigation of the Eyder between Rendſburgh and Tonningen, occaſioned by numerous ſhoals of ſhifting ſands, will prevent the complete ſucceſs of this canal. Ships ſailing from the Baltic to Engliſh or French ports, will without doubt prefer the navigation round the Cattegate, with all its dangers and difficulties. The trade of Kiel, however, will at all events be greatly increaſed by this canal ; but the principal depoſitory of the merchandiſe will be at Rendſburgh. Coxe's Travels, vol. v.

The canals of Holland and Flanders are innumerable ; and they ſerve the purpoſe of our public roads, ſo that the inhabitants may travel by means of them in their trehſchuyts and barges, and convey commodities for conſumption or exportation, from one part of the country to another, as occaſion requires. An inhabitant of Rotterdam, it is ſaid, may, by means of theſe canals, breakfaſt at Delft or the Hague, dine at Leyden, and ſup at Amſterdam, or return home again before night. By them alſo a prodigious inland trade is carried on between Holland, France, Flanders, and Germany. When the canals are frozen over, they travel on them with ſkaits, and perform long journies in a very ſhort time, while heavy burdens are conveyed in carts and ſledges, which are then as much uſed on the canals as in our ſtreets. The profits which have accrued from theſe canals have been immenſe ; and their amount almoſt exceeds belief. It is ſaid, that they have yielded more than 250,000l. for about 40 miles of inland navigation. The canals of Holland are generally 60 feet wide, and ſix deep, and are kept cleanſed ; the mud, as manure, being very profitable. They are generally level, and need no locks ; and they are commonly elevated above the country for the purpoſe of carrying off the waters, which in winter inundates the land. In the province of Delftland, not more than 60 miles long, 200 wind-mills are employed in ſpring to raiſe the water into the canals. On the dams or banks by which they are bordered, and which are kept in repair at a very conſiderable expence, depends the ſecurity of the country from inundation. The canals of Flanders, ever ſince their trade has declined, and the cities erected on their banks have decayed, have been very much neglected. They indicate, however, the former flouriſhing and proſperous ſtate of the country. So early as the 12th century, large canals were cut ; and they anſwered the purpoſe of inland commerce as well as of draining the land. The ſpacious canal of Bruſſels, begun in 1531, and completed in 1560, extends from this city to the Scheldt, which opens a communication with Holland, and by the canals of Flanders with the ocean. The canals of the other Dutch and Flemiſh towns will be mentioned under their reſpective articles.

France has from a very diſtant period exerciſed its ingenuity and activity in the conſtruction of canals for inland navigation. We muſt content ourſelves with a curſory mention of ſome of the principal. The canal of Briare, called alſo the canal of Burgundy, was begun under Henry IV. and finiſhed in the reign of Louis XIII. It opens a communication between the Loire and the Seine, and then between Paris and the weſtern provinces. Commencing at the Loire near Briare, it paſſes to Montargis, joins the canal of Orleans, which was begun in 1675, and has 20 ſluices, and falls into the Seine near Fontainbleau. It has 42 locks and ſluices; and is of great uſe in inland commerce. The canal of Picardy connects the river Somme with the Oiſe; and beginning at St. Quintin, joins the Oiſe, and affords a ready conveyance to Paris for the grain of Picardy, the ſea-coal, wood, butter, copper, and ſpices from the northern provinces of the kingdom, and from Holland. The moſt conſiderable work of this kind is the canal of Languedoc, called the canal of the two ſeas, which forms a junction between the Ocean and the Mediterranean. It was firſt projected under Francis I., but begun in 1666, and finiſhed in 1681, under Louis XIV., during the miniſtry of Colbert, and by the ſkill of Riquet, the engineer. It eſtabliſhed a ready communication between the two fertile provinces of Guienne and Languedoc, and extends from Cattee in the bay of Languedoc, to the Garonne below Thouloſe, being provided at proper intervals with 114 locks and ſluices. In ſome places it is conveyed by aqueducts over bridges, under which other rivers purſue their courſe. Near the town of Beziers, it was conveyed under a mountain by a tunnel, then thought ſingular and extraordinary, but now common, 720 feet in length and lined with free ſtone. At St. Ferriol it derives a ſupply of water from a reſervoir containing 595 acres. Its breadth is 144 feet, including towing-paths; it is ſix feet deep, and its length 64 French leagues, or about 180 miles. The expence of its conſtruction was about 540,000l., defrayed partly by the king, and partly by the province of Languedoc. On the reduction of the army and navy in 1782, after the concluſion of the American war, the diſbanded ſoldiers and ſeamen were employed in the conſtruction of three navigable canals; viz. one, called the canal of Dehune, extending from Chalon-ſur-Saone to the town of Dijoin on the Loire, through an interval of 21 leagues, and forming a junction with the Saone and the Rhone: a ſecond, called the canal of Burgundy, reaching from St. Jeane-de-l'Aune to the village of Roch, between St. Florentine and Joiſny, through a ſpace of 52 leagues, and opening a communication between the Saone, the Rhine, the Yonne, and the Seine; and a third, called the canal of Neuf-Briſſac, which commences at the village of St. Symphorin, on the Saone, and paſſing the city of Beſançon, is continued below Straſburgh, forming a junction of the Saone with the Rhone, and of the Ill with the Rhine. By theſe canals goods may be conveyed at a cheap rate from Marſeilles, the Mediterranean, Italy, and Switzerland, to the bay of Biſcay and the Ocean, and alſo to Holland and Germany, as well as to Flanders and the Auſtrian Netherlands; and during any future war with England, France will be able to ſupply, by theſe canals, her dock-yards at Marſeilles and Toulon, and alſo her grand arſenal and dock-yards at Breſt and Rochfort, with all ſorts of commodities from the Baltic, without hazarding a voyage by ſea. It would be endleſs to enumerate all the canals, projected or actually executed in France, and forming an eaſy intercourſe between the different diſtricts of this extenſive country. A ſurvey has lately, in 1802, been made of the little river Buzeg or Bureg, with a view of its being brought to Paris in the ſame manner as the New River is brought to London, and of being laid into the ſtreets and houſes by pipes, fire-plugs, and engines, for the purpoſe of cleanſing the ſtreets, as well as accommodating the houſes. Phillips's Inland Navigation, p. 75. 8vo.

Spain has not been altogether inattentive to the improvements likely to reſult from inland navigation. At former periods it has been often propoſed to dig a canal through the iſthmus of Darien, from Panama to Nombre de Dios, and thus to make a ready communication between the Atlantic and the South Seas, and to open a ſtraight paſſage to China and the Eaſt Indies. The project, however, has been conſidered as chimerical, and treated with ridicule. The improvements meditated at home are of much greater importance: but though the inland navigations of Spain have been commenced upon principles both of grandeur and utility, they have been ſuffered to languiſh through the want of reſources, and the tardy meaſures of the court. The great canal of Arragon afforded, in 1785, ſome hopes; but it ſeems to remain in an imperfect ſtate. Two branches, however, are completed: thoſe of Tauſtre, and the imperial canal, both of which begin at Navarre and terminate in the river Ebro, and they have already proved ſources of induſtry to all the diſtricts through which they flow, and rendered the fields fertile. One of theſe canals is conducted over the valley of Riojalon, by an aqueduct 710 fathoms in length, and 17 feet thick at the baſon. Another canal called the canal of Caſtile was projected to begin at Segovia, about 40 miles N. of Madrid, and to extend to the bay of Biſcay, through a diſtance of 140 leagues. This canal is 56 feet wide at the top, 20 feet at the bottom, and nine feet deep, but the completion of it will require many years. The canal of Guadarama was planned in 1784, and being conducted with ſpirit, is probably now completed. It was to commence at the foot of the mountains of Guadarama, near the Eſcurial, and to proceed to join the Tagus, afterwards the Guadiana, and terminate at the Guadalquivir, above Anduxar. Another canal was alſo begun to join the river Manzanares to the Tagus; but the work was ſuſpended. The canal of Murcia was found, after its commencement, to be impracticable. Phillips's Inland Navigation, p. 75, &c.

The Americans poſſeſs a country capable of great and eaſy improvement by internal navigation. To this object they are not inattentive. For an account of their projects and actual progreſs in this buſineſs, we muſt refer to Phillips's Inland Navigation, p. 571, &c., or to the Journals of Mr. Elkanah Watſon.

CANALS, *the Britiſh*; from the great influence which they appear to have had, among other cauſes, during the laſt half century, in promoting the rapid increaſe of our commercial greatneſs as a nation, have induced us to lay before our readers a very full account, not only of the preſent exiſting canals, but of the principles and practice of canal making, in the united kingdoms. As very few of the Engliſh, Welch, Scotch, and Iriſh rivers, are of ſufficient magnitude, and free from ſhoals, to anſwer the purpoſes of navigation far into the country from the ſea, without the aid of art, conducted upon ſimilar principles to thoſe uſed in canal-making; and as nearly all our canals connect with the navigable rivers, and act in ſome meaſure, as extenſions of them further into the country, we have found it expedient to include under this article, whatever we have been able to collect on the ſubject of the *Inland Navigation of the United Kingdom.*

That the navigation of our rivers, by ſhips or ſmaller veſſels has long been an object of conſiderable importance, will appear from *magna charta*, which has made a ſpecial proviſion in the 23d chapter, for the putting down of weirs and other obſtructions in the rivers of England; and from ſtat. 25 Edw. III. c. 4. which ſets forth, that "whereas the common

mon paſſages of boats and ſhips in the great rivers of England, be oftentimes annoyed by inhanſing gores, weres, ſtakes, &c. in great damage of the people: it is eſtabliſhed, the ſame ſhall be cut and utterly pulled down, without being renewed, and that writs be ſent to the ſheriffs to do execution." After two other unſucceſsful attempts by ſtatutes in the ſucceeding reigns, to prevent the free navigation of the rivers from being obſtructed by individuals, intent upon fiſhing, embanking land, or building mills, bridges, or making fords, the ſtatute of the 4th of Henry I. chap. 12, appointed ſpecial commiſſioners for carrying the above ſtatutes into effect; whoſe powers were continued and enforced by two other acts, prior to the 23d of Henry VIII. chap. 5. which being entitled, "The Bill of Sewers with a proviſo," appointed a general commiſſion of ſewers, with large powers that are ſtill in force and acted upon, for making laws and ordinances, and compelling obedience thereto, for the "removing and preventing of impediments and annoyances on rivers, ſtreams, and floods, whereby the paſſage of ſhips and boats might be letted or interrupted." And by the ſtatute of Edward VI. chap. 8, the laſt mentioned and former ſtatutes were confirmed and made perpetual. During the above period, ſeveral other ſtatutes were alſo made, for removing obſtructions in particular rivers, of ſome of which we ſhall have occaſion to ſpeak when we come to mention thoſe rivers.

The general laws of the land proving ſo very ineffectual for protecting internal navigation from the encroachments of individuals and the effects of neglect, this probably ſuggeſted the propriety of thoſe particular grants or ſtatutes which we find enabling corporations, and in ſome inſtances individuals, to take particular rivers under their charge, and to receive tolls or dues from the veſſels navigating within their particular diſtrict. In proceſs of time, as population increaſed, and the advantages of water carriage became more apparent, further grants and acts of parliament were made, authoriſing companies or individuals to extend the navigation on certain rivers further into the country, generally to reach ſome city or great town; theſe acts, ſome of which we ſhall particularize hereafter, generally enabled the parties to deepen, and in ſome inſtances to ſtraiten the courſe of their rivers, to embank them where too wide, to erect jetties and ſluices, to make flaſhes for ſurmounting the ſhallows or rapids, and in later times to erect pound-locks for gaining the aſcent to the different mill-dams upon the river. But the conſtant tendency of rivers, eſpecially rapid ones, to caſt up banks of ſand or gravel in particular places, their deficiency of water in times of drought, and ſuperabundance in times of flood, the ravaging effects of theſe laſt in deſtroying the works erected for the uſe of the navigation; as happened on the river *Avon* between Chriſtchurch and Saliſbury; on the river *Stour*, between the Severn and Stourbridge; on the river *Calder*, between Wakefield and Eſland, and on ſeveral others which might be mentioned; the great labour and difficulty of towing or dragging veſſels againſt the ſtream, eſpecially where there was not a towing-path for horſes, near to the channel of the river, and yet not ſubject to be overflowed and rendered uſeleſs in time of floods; the very lengthened courſe of moſt rivers, ariſing from their ſerpentine, and, in ſome inſtances, varying channel, was not alſo among the ſmalleſt of the difficulties attending them: theſe, at length, ſuggeſted the propriety of leaving the bed of the rivers in ſome inſtances for a new cut for the navigation acroſs a neck of land, with a pound-lock at its lower extremity. As theſe ſide cuts and pound-locks were increaſed in number, to ſhorten the courſe of the rivers, their ſuperior advantages became ſo apparent, that a company of gentlemen and merchants, who had in 1755 obtained an act of parliament authoriſing them to make *Sankey Brook* navigable from the Merſey river to near St. Hellins, in Lancaſhire, with the powers at that time uſual in navigation acts, for the purchaſing of land and other things neceſſary for the intended navigation, at a fair eſtimate to be made by commiſſioners named in the acts; they determined, after mature deliberation, to avoid the bed or channel of the brook altogether, and to make one entire new cut or canal, as near as convenient to the bed of the river, with locks thereon, in ſuch places as the falls of the ground ſhould render neceſſary; and this canal they accordingly effected about the year 1760, ſupplying its higheſt pound or level with water, by a cut or fender from the Brook. Thus navigable canals had their riſe in England; but, a leſs fortunate ſet of gentlemen, who under the power of an act obtained in the year 1730, for making the river *Stroudwater* navigable, from the river Severn to near the town of Stroud, although the act empowered them "to make as many new cuts as they may judge proper, and of what length and breadth they ſhall think convenient;" yet when they had, about the year 1774, determined upon following the example of the *Sankey* proprietors, and in imitation of the duke of *Bridgewater's*, and ſeveral other canals, which had then been executed or were begun; by cutting a canal on the ſide of the Stroudwater river, they were ſtopped by an expenſive law-ſuit, carried on by certain mill and land-owners in the neighbourhood: whereby the diſtinction between the river navigation acts, and canal acts was eſtabliſhed by the Court of Exchequer, before which the caſe came to be argued.

About the year 1757, the *Duke of Bridgewater*, acquainted fully, no doubt, with what had been near 80 years before effected, on the canal of Languedoc, in the South of France, and ſince in different parts of the Continent, conceived the idea of a canal for the purpoſe of conveying coals from his eſtate at Worſley in Lancaſhire, to Salford near Mancheſter. His grace, profiting as no doubt he did, by the works of that great French engineer, *Francis Riquet*, and by the advice of that great natural and ſelf-taught genius *James Brindley*, whom his grace called off, about the year 1758, from his employment as a mill-wright and engine-maker in this country, to perfect, and carry into execution, the great and important ſchemes which he had projected, and for which he propoſed and brought into parliament the firſt act, with powers adequate to the great and extraordinary undertaking, of cutting a canal of ſeveral miles in length, not in the direction of any river or ſtream of water, but croſſing the courſe of ſeveral brooks, roads, &c. and through the lands of a vaſt number of different perſons, all of whom were to be fully compenſated, though deprived of the power of withholding their lands or waters, or in any way obſtructing the deſign. In theſe reſpects, the *Duke of Bridgewater* has not improperly been called the father of canals in England, while his engineer, the late *Mr. Brindley*, by his maſterly performances on the Duke of *Bridgewater's* canal, altered and extended as the ſcheme thereof was, by three ſubſequent acts of parliament, has ſecured to himſelf, and well it ſhould ſeem, from a compariſon of the great features, and minutiæ of execution in this the firſt canal, with moſt others in this country, even of the lateſt conſtruction, long continue to hold, that rank among the Engliſh engineers, to which *M. Riquet* ſeems entitled among foreigners.

The courſe, thus happily opened by the Duke of Bridgewater, was quickly followed by new ſets of adventurers, who were ſeen applying to parliament in almoſt every ſeſſion, for powers to raiſe a joint ſtock on transferrable ſhares, and to make and maintain canals in moſt parts of the kingdom, many of which have been long completed, as our ſubſequent account of them will ſhew, and have contributed in a moſt eminent degree to the improvement of the country, as well as to the enriching of the individuals concerned in a great number of inſtances; in the laudable zeal of adventurers to extend, and of the people of great towns and proprietors of mines and great manufactories to receive, the benefits of inland navigation; numerous ſchemes have been adopted, where from the actual ſcarcity of water, or its previous appropriation to mills, a canal with locks was impracticable. One of the firſt of theſe ſchemes for diſpenſing with locks, was that of *Mr. Bridge*, about the year 1759, upon the *Stroudwater* river before mentioned, where the cargoes of the boats were diſpoſed in a number of boxes or frames, juſt adapted to the ſize of the boats; which boxes of goods were drawn up by cranes to be lodged in other boats on the higher level, and the reverſe in deſcending; which method was afterwards more ſucceſsfully practiſed on *Bridgewater's* canal at Worſley, at Brieley Hill on the *Shropſhire* canal, and other places. The next mode ſeems to have been adopted by *Mr. Davis Drekart*, near the Tyrone collieries on the intended connection with *Blackwater* navigation in Ireland, about the year 1776; and afterwards by *Mr. William Reynolds* on the *Ketley* canal, where the boats were dragged up or let down inclined planes, not very different from the rolling bridges, long before in uſe in Holland and Flanders.

The neceſſity of an expeditious and cheap mode of conveying coals from the pits to the keels or ſhips, had, as early as the year 1680, introduced the uſe of wooden railways, for the waggons to move upon, between the *Tyne* river and ſome of the principal pits, and theſe by degrees became extended to a great number of other coal-works. Since the more general introduction of caſt iron, and its cheaper conveyance by means of canals, iron rails have been ſubſtituted in the place of the wooden ones before mentioned; and the uſe of inclined planes, or parts of the rail-way having a much greater declivity or ſlope than it is practicable to drag carriages up by means of horſes, has become very frequent in parts where the riſe of the ground required it, machinery being on theſe inclined planes adopted to ſupply the place of horſes.

Several years ago, an act of parliament was obtained by *Homfray, Hill, and Co.* for an iron rail-way, or tram-road from *Cardiff* to *Merthyr*, by the ſide of, and as a rival ſcheme of the *Glamorganſhire* canal, for 9 miles or more in length; ſince which, ſeveral other acts have been paſſed for rail-ways, and ſeveral of them executed, to the great benefit of the country, and the companies who conſtructed them; it has alſo become common within the ſame period, to authoriſe canal companies to conſtruct rail-ways, as collateral branches from their canal, to mines or other great works or to large towns within certain diſtances of ſuch canals; by which their benefits have been amazingly extended: moſt of the latter acts have alſo authoriſed the adoption of rail-ways, of inclined planes, or of any of the expedients above-mentioned, or others as ſubſtitutes for locks, in ſuch parts thereof, as are not readily to be ſupplied with water, adequate to the waſte which locks occaſion. So many of theſe compound ſchemes for leſſening the expence of carriage have been already executed, or are in hand, that we have found ourſelves compelled, in order to preſent our readers with a connected and uſeful view of the ſubject, to include what we have to ſay on the ſubject of *rail-ways*, in the preſent article, as well as treat therein of *navigable rivers*, for the reaſons before ſtated.

Great Britain as well as every other iſland, and even a continent taken as a whole, has a range of high land paſſing nearly its whole length, which divides the ſprings and rain waters that fall to the oppoſite coaſts: we ſhall call this range dividing the eaſtern and weſtern rivers of Britain the *grand ridge*, and ſhall in our accounts diſtinguiſh on which ſide, or how each canal is ſituate, in reſpect thereof: and here it will be proper to remark, that no leſs than 22 of our canals now do or are intended to paſs this grand ridge, forming as many navigable connections between the rivers of the eaſt and weſt ſeas! theſe are the *Inverneſs and Fort-William*, *Forth and Clyde*, in Scotland; the *Leeds and Liverpool*, *Rochdale*, *Huddersfield*, *Trent and Merſey*, *Staffordſhire and Worceſterſhire*, *Wyrley and Eſſington*, *Birmingham*, *Dudley*, *Worceſter and Birmingham*, *Stratford*, *Warwick and Birmingham*, *Coventry*, *Grand Junction*, *Oxford*, *Thames and Severn*, *Wilts and Berks*, *Kennet and Avon*, *Dorſet and Somerſet*, *Grand Weſtern*, and *Bude and Launceſton*, in England: and what is not a little remarkable is, that the *Dudley* canal croſſes this grand ridge *twice*, the two ends being on the eaſtern ſide, and the middle part on the weſtern ſide thereof; the Kennet and Avon croſſes the eaſtern and weſtern branches, into which it divides on the Chalk Hills, weſt of Marlborough, by which parts of this canal are in the drainage of the weſt, the ſouth, and the eaſt ſeas! the *Coventry* canal alſo, by means of its Bedworth branch, croſſes the grand ridge twice. The populous and remarkable town of *Birmingham* is ſituate on high ground, near to the grand ridge, and has ſix canals branching off in different directions, either immediately therefrom or at no great diſtance, and what is ſingular, owing to a loop, or ſudden bend of the ridge at this place, no leſs than five of them traverſe the grand ridge, either by means of tunnels or deep-cutting.

When we propoſe to lay before our readers a more full and methodical account than has been given of the Britiſh canals, on which large ſums of money have been expended by individuals, and from which important and laſting benefits have been derived by the inhabitants in their immediate vicinity and by the kingdom at large; it is needleſs to ſtate any formal arguments, in anſwer to the miſtaken objections, which were 40 years ago commonly circulated, whenever a new canal was in contemplation; ſuch as their waſting of land, producing noxious and humid vapours, deſtroying the breed of our draught horſes, leſſening the coaſting trade and the nurſery of ſeamen, injuring old mines and eſtabliſhed works by enabling new ones to be opened, introducing pilfering workmen and boatmen into the country, &c. &c. To the more ſerious objections, ariſing from the cutting of eſtates and fields in two; the taking of water from mills, &c.; interfering with former navigations by canals or rivers, and even with roads, on which, in ſome inſtances, large ſums have been expended, and remain not reimburſed; to theſe and many others, we ſhall have the beſt opportunity of replying, when we come to mention the equitable proviſions which individuals have propoſed, and the legiſlature have in ſo many inſtances enforced, for ſecuring to every one an adequate compenſation for what he is called upon to give up.

General arguments in favour of canals are ſuperſeded by the rapidly improving and thriving ſtate of the ſeveral cities, towns, and villages, and of the agriculture alſo near to moſt of the canals of the kingdom, the immenſe number of mines of coal, iron, limeſtone, &c. and great works of every kind to which they have been conducted, and to which a large portion of them owe their riſe, are their beſt recommendation.

Juſtice requires our acknowledging the aſſiſtance we have received in compiling this account, from the *General Hiſtory of Inland Navigation by John Phillips*, from the three numbers which are publiſhed of *John Cary's Navigable Canals of Great Britain*, from *C. Smith's*, *George Allen's*, and *Laurie and Whittle's* maps of the canals, &c.; from *J. Cary's large map of England, Wales, and part of Scotland*; from *Robert Fulton's Treatiſe on Canal Navigation*, from *William Chapman's Obſervations on Canal Navigation*, from *Joſeph Plymley's Agricultural Report of Shropſhire*, from *Zach. Allnutt's Conſiderations on the Navigation of the Thames*; from *Thomas Badeſlade's*, and from *Nathl. Kinderley's Accounts of the Navigation of Lynn and Wiſbech*, &c. from the *Agricultural* and *Monthly Magazines*, from *Dr. Anderſon's Recreations*, from the *Annual Regiſter*, from *Thomas Telford's Reports on the Caledonian Canal, &c.*; and from the writings of others, to whom we particularly refer.

To *Mr. William Smith*, engineer, of Buckingham-ſtreet, London, we are indebted for many valuable hints and information given on many points, as we are alſo to *Mr. Benjamin Bevan*, engineer, of Leighton Buzard, Beds.

When it is propoſed to form any canal, the choice of a ſkilful and experienced engineer is an object of primary conſideration. Without due attention to this object, many impracticable projects may be adopted, and large ſums of money may be expended without accompliſhing any important and uſeful purpoſe. In ſuggeſting the principal qualifications that are neceſſary for rendering perſons competent to be conſulted or employed in undertakings of this kind, we ſhall merely ſpecify ſome of thoſe that have in an eminent degree diſtinguiſhed, or that ſtill no leſs conſpicuouſly diſtinguiſh ſeveral of our own countrymen. A ſkilful engineer ſhould undoubtedly poſſeſs a conſiderable degree of mathematical knowledge. Calculations, of which ſome are of the moſt abſtruſe and laborious kind, will frequently occur; and he ſhould, therefore, be well acquainted with the principles on which all calculations are founded, and by which they are to be rightly applied in practice. An engineer ſhould alſo have ſtudied the elements of moſt or all of the ſciences, immediately connected with his profeſſion; and he ſhould particularly excel in an acquaintance with the various branches of mechanics, both theoretical and practical. His knowledge ſhould comprehend whatever has been written or done by other engineers, and he ſhould have information in every department of his office from an accurate examination of the moſt conſiderable works that have been executed in all the various circumſtances that are likely to occur. It is neceſſary, that he ſhould be a ready and correct, if not a finiſhed, draughtſman. He ſhould alſo be converſant with the general principles of trade and commerce; with the various operations and improvements in agriculture; with the intereſts and connection of the different owners and occupiers of land, houſes, mills, &c.; and with all the general laws and deciſions of courts, pertaining to the objects connected with his profeſſion. By an extenſive acquaintance with the diſpoſition, inclination, and thickneſs of the various ſtrata of matter, which compoſe the ſoil or land of the Britiſh iſlands, he will be able to avoid many errors incident to thoſe who are deſtitute of this knowledge, and to have the courſe and cauſes of ſprings, to which it leads. As the laſt, though not the leaſt, of theſe qualifications of an engineer, which we ſhall enumerate, we ſhall add, that he ſhould be a man of ſtrict integrity. If, at this day, the affairs of any canal company ſhould be entruſted to perſons deficient in all or the greater part of the qualifications above enumerated, the managers of ſuch a company will thus incur a ſerious reſponſibility to the proprietors and to the public. In this connection we think it right to mention an inſtitution that had its riſe in the year 1771, viz. "the Society of Civil Engineers," as admirably calculated to extend the influence of our preſent and more experienced engineers, and to bring forward to public notice others, who, in the courſe of events, are deſtined to ſecond them. For further particulars relating to this ſociety, we refer to the preface of the firſt volume of Smeaton's Reports, Nicholſon's Journal 4to. vol. ii. and the article SOCIETY of *Civil Engineers*.

A proper engineer being fixed upon, the adventurers ſhould not tie him down too cloſely, by reſtrictions as to time, but allow him leiſure to conſider, digeſt, and reviſe again and again, the different projects and ways, which will naturally in moſt inſtances preſent themſelves to him in an extenſive and thorough inveſtigation. The engineer ſhould be allowed to chuſe and employ the moſt competent aſſiſtants, and to call in and occaſionally to conſult the opinions of eminent or practical men, as land-ſurveyors, agents of the neighbouring landed property, the principal and moſt expert commercial men of the diſtrict, and who are beſt acquainted with its trade and wants, any eminent miners, &c. &c.; and ſuch men the engineer ſhould be authorized liberally, and at once to remunerate for their ſervices and intelligence.

Previous to the beginning of any minute ſurvey or ſyſtem of levelling, the engineer ought to viſit perſonally, and endeavour to make a juſt eſtimate, and preſerve memorandums of all the objects within the diſtrict under conſideration; as of the trade and importance of all the towns likely to be affected by the undertaking, of all mines of coal, iron, &c. quarries of lime-ſtone, free-ſtone, ſlate, &c. or the ſituation where ſuch can be found, of all manufactories of heavy and cumbrous goods, and other extenſive works; and generally of every thing likely to furniſh tonnage for a canal. By this time, if the diſtrict under conſideration be of very conſiderable length, more than one, and perhaps ſeveral, different routes for the propoſed canal have preſented themſelves: and it will be proper, while the engineer's aſſiſtants are carrying levels (uſing good ſpirit levels with teleſcopic ſights) along each, and making rough ſections of the ground, or brook or river along each line, himſelf to viſit and paſs along each of theſe, noting and weighing more particularly the principal difficulties which preſent themſelves in each route, as ſummits or hills to be paſſed, or tunnelled through, vallies to be embanked acroſs, with aqueducts over rivers or brooks, the greater or leſs plentiful ſupply of water, particularly at the ſummit levels, and how far the ſprings and ſtreams of water are at preſent appropriated or eſſential to mills or gentlemen's pleaſurable purpoſes, or to irrigation, or the land occupied by parks, turnpike roads, &c. The advantages of each route ſhould alſo be as carefully noted; as the ſhortneſs of diſtance, connection with great towns, mines and works either on the line or by ſhort and practicable ſide cuts or branches, the ſmalleſt number of locks, bridges, culverts, &c. In weighing all theſe circumſtances, in order to determine on the moſt adviſable line, it ſhould never be loſt ſight of, that a canal is altogether a mercantile ſpeculation, and cheapneſs of conveyance is the grand deſideratum thereof: where, therefore, but few, if any, great towns, works, or mines are found upon a propoſed line, and the principal object is to form a connection between the canals of a diſtrict more fortunately circumſtanced in theſe reſpects, and the metropolis, or a great town, as in the caſe of the *Grand-Junction* canal lately completed, it is evident, that much ought to be done to obtain the ſhorteſt route that is practicable: if, on the contrary, the diſtrict under conſideration has great towns, mines of coal, or great works diſtributed about it, ſome miles in the total diſtance may be properly allowed, and a more circuitous route adopted, to embrace as many as poſſible of theſe objects, particularly coal-works; for it has been remarked, that the carriage of coals gives riſe to the principal revenues of moſt canals; and ſome have even contended, that no canal can anſwer to the proprietors unleſs the carriage of coals be its principal object: there are, doubtleſs, ſome exceptions to this rule. It may be concluded, upon the whole, that no canal can be completed and brought into uſe, but the inhabitants and the agriculture of the diſtrict will ſhortly feel great benefit from it, whatever may be the reſult to the proprietors; yet in the ſtage of the buſineſs of which we are treating, it is the peculiar duty of the engineer to ſtudy the intereſt, and bring forward the probable advantages of the proprietors, fairly and without exaggeration, in order that the ſubſcription may fill, and the work be enabled to proceed. Before determining upon the route of a canal, its connection with the neighbouring canals or river-navigations ſhould be well conſidered, and the engineer ſhould inform himſelf accurately of the quantum of benefit or injury likely to reſult to each of ſuch exiſting navigations by the effecting of the new one, or how far their rivalſhip, or that of any other ſcheme which may at the time be in agitation, is likely to effect the one he is employed upon; in all the practicable routes, which preſent themſelves for the new canal.

The moſt eligible route for the canal being ſettled in the engineer's mind, he will then proceed to make a rough calculation of the quantity of goods of each different kind, which may be expected to paſs upon the line in a given time; he will alſo examine all the canals and rivers which the propoſed canal is to connect with, and aſcertain the widths and depths thereof, the ſizes of their locks, and of the veſſels uſually navigating them. The engineer will now be able, well conſidering the nature of the ground the canal is to paſs over, to determine on the moſt proper dimenſions for the intended canal, and whether the probable ſupply of water renders it practicable to effect the riſes and falls by the ordinary mode of locks; or whether inclined planes, or any other of the expedients which we ſhall more particularly enumerate hereafter, ſhould be adopted: or even, whether a rail-way, in whole or in part, may not be preferable to a canal. The mind of the engineer will properly be exerciſed upon theſe queſtions, before a more minute and expenſive ſurvey and planning of any particular line are entered upon; becauſe, the line, though paſſing through the ſame tract of country, will generally require to be conducted in a very different place for great lengths together, according to the ſize of the propoſed canal; and inclined planes, or a rail-way in whole or in part, will introduce a ſtill greater diverſity in the routes that ought, under the different circumſtances, to be purſued.

*Robert Fulton*, in his 4to. Treatiſe on Canal Navigation, publiſhed at London in 1796; *William Chapman*, in his 4to. Obſervations on the various Syſtems of Canal Navigation, London, 1797; *Thomas Telford*, in J. Plymley's 8vo. General View of the Agriculture of Shropſhire, London, 1803; *Edmund Leach*, *Dr. James Anderſon*, and others in different works, have recommended and enforced, upon principles more or leſs general and true in their application, a variety of ſchemes and methods of conveyance, by ſmall canals, inclined planes, rail-ways, &c. of which we ſhall take notice under their proper heads, and of which the engineer will of courſe avail himſelf, as far as they appear applicable; as well as of any other inventions, which his own ingenuity or that of others may ſupply. Long levels may, in ſome inſtances, be obtained, without inordinate expence; and will often prove of great utility, in the ſaving of the time and trouble of paſſing locks in the neighbourhood of great towns, as in the caſes of Coventry, which has the benefit of more than 73 miles of level navigation on the *Coventry*, *Aſhby de la Zouch*, and *Oxford* canals; and of Mancheſter, which has [illegible] miles of level water by *Bridgewater's*, and *Merſey and I*[illegible] canals, including 12 miles in the tunnel to the *duke of Bridgewater's* coal-works in Worſley Hill: Birmingham has 4[illegible] miles of ſtill water, by means of the old *Birmingham*, the *Worceſter and Birmingham*, the *Dudley* and the *Stratford* canals; and this upon ſo high a level, that the three laſt canals croſs the grand ridge in that ſpace: Lancaſter and Preſton have 42½ miles of level on the *Lancaſter* canal; Wolverhampton enjoys the benefit of a level 40 miles in length, on the old *Birmingham*, and *Wyrley and Eſſington* canals; Liverpool has 28 miles of level on the *Leeds and Liverpool*, and Blackburn, 24 miles upon the ſame canal; Baſingſtoke has 22 miles upon the *Baſingſtoke* canal; Whitchurch 21 miles on the *Elleſmere*; Devizes 20 miles upon the *Kennet and Avon*; Bottesford 20 miles upon the *Grantham*; London enjoys the benefit of about 19 miles of level to Paddington, upon the *Grand Junction* canal; Glaſgow 18 miles on the *Forth and Clyde*; Glouceſter is to have 1[illegible] miles upon the *Glouceſter and Berkley*; Shrewſbury has 15½ miles on the *Elleſmere*; Stainsforth 15 miles on the *Stainſforth and Keadby*; Abergavenny 14 miles on the *Brecknock and Abergavenny*; Market Harborough 13½ miles on the *Leiceſterſhire and Northamptonſhire Union*; Shrewſbury 11½ miles on the *Shrewſbury*; and Cromford 11 miles of level on the *Cromford* canal. Another benefit will ſometimes occur from long levels, by the bringing of all, or of a conſiderable number of the locks near together, as at Runcorn on *Bridgewater's* canal, by which they are more effectually looked after and kept in repair. Should it be neceſſary to return the water let down by the lockage, again into the higher pound by the power of engines, as is done on the old *Birmingham*, the *Barnſley*, and many other canals, the having of conſiderable falls in one place will be of material conſequence; but ſtill more ſo if inclined planes are to be uſed inſtead of locks, as on the *Shropſhire*, *Shrewſbury*, and *Ketley* canals. In conducting the line of a canal, it will always be adviſable, if other circumſtances will permit, to bring two or more locks near together, and to erect a lock-houſe for the reſidence of a careful and proper perſon upon the ſpot, to look after and aſſiſt the bargemen in working the locks; where this had not been attended to upon ſome canals, but ſingle locks were placed at great diſtances from each other, the company have, from experience of the damage ſuch locks ſuſtain, found it neceſſary to employ great numbers of lock-keepers, and often to build houſes for the ſuperintendance of ſingle locks. Mr. *Chapman*, who appears to have well weighed the queſtion, whether large or ſmall canals ought to be adopted under different circumſtances, obſerves, "that the ſyſtem of ſmall canals is particularly eligible in all countries where lime-ſtone, coal, iron-ore, lead, and other ponderous articles, not liable to damage from being wet, or likely to be ſtolen, are the objects chiefly to be attended to; and where the declivity of the country runs tranſverſely to the courſe of the canal, which will generally be the caſe along the ſides of mountains, at an elevation above the irregular ground at their feet. In thoſe ſituations, the great falls or inclined planes may be made at the forks of rivers, ſo that the upper levels may branch up both the vales, and thus give the moſt extended communication. A ſituation ſuited for thoſe canals will often be found in countries that are not abſolutely mountainous, but where the ground regularly declines towards the vales of large rivers." The principles for which Mr. *Leach* has ſo ſtrenuouſly contended, of reverſing the uſual order of beginning navigations at the loweſt points or the ſea, and extending them up the vallies towards the ſummits, and, inſtead thereof, beginning near the ſummit or ſource of the water, and continuing the level till the greateſt practicable falls are obtained for inclined planes, would, unleſs the moſt enormous expences were incurred for tunnels, deep-cutting, and embankments, prove too crooked and circuitous for a ready conveyance, as happened on the *Bude and Launceſton* canal, which was propoſed to purſue a ſerpentine courſe of 81 miles, between two places whoſe direct diſtance is no more than 28 miles! The long level of the *Oxford* canal, at its northern end, of which we have ſpoken above, appears among the moſt crooked of thoſe canals which have been executed, and is particularly ill adapted, to the great throroughfare or communication which it forms with other canals. Canals which are to form an immediate connection between the ſea or tide-way at different places, as the *Inverneſs and Fort William, Crinan, Forth and Clyde,* the *Iſle of Dogs,* and the *Glouceſter and Berkley,* muſt be of large dimenſions, or the principal advantages of ſuch a communication would be unattainable; in like manner, the communications between the ſea, and docks or harbours, will ſome of them require to be of ſtill larger dimenſions, as the *Grimſby, Ulverſtone, Dee* new channel, &c. A ſyſtem compounded of *water-levels,* or lengths of canal on different levels without communication by locks, may ſometimes be found adviſable, as on the *Shropſhire, Shrewſbury, Ketley, Leiceſter,* &c. The advantages of being able to conduct a canal, in many inſtances, upon water-tight ſtrata, inſtead of rocky or porous ſoils, and perhaps without loſing ſight of any of the other important conſiderations mentioned, are ſufficiently great to induce engineers to become acquainted with the arrangement and particulars of the *ſtrata* within their diſtrict, by a minute and careful examination, or to call in the aſſiſtance of thoſe beſt informed on ſuch points. We have purpoſely omitted, till now, to mention the conſideration of the value or quality of land to be purchaſed for the uſe of the propoſed canal by different routes; convinced that ſome late canals have been materially injured by the narrowmindedneſs of thoſe who would avail themſelves of cutting through common or low-prized land: even the general conſideration of expence, in the works of a propoſed canal, ſhould hold but a ſubordinate place in the mind of an engineer in the preſent ſtage of the buſineſs, becauſe contracted views in this reſpect may fruſtrate the attainment of a great portion of the benefits to be expected; and it cannot be doubted that any ſcheme of conveyance will beſt anſwer to the adventurers and the public, when conducted upon the principles moſt adapted to the caſe, let the expence be what it may; and fortunately, the commercial and public ſpirit, aided by the means of individuals collectively in this country, has long ſhewn itſelf equal to any enterprize however bold, where advantages can be ſhewn materially to preponderate.

In the particular ſurvey of the line propoſed, all the knowledge of the moſt expert and competent engineers, with the moſt able aſſiſtants, will be requiſite. The rough ſection of the propoſed line, before taken, will enable the engineer to ſee the places of the heights and breadths of the various ſummits, or ranges of high land that are to be paſſed, and whether any two or more adjacent ones can be connected by a long ſummit level, without deſerting any conſiderable town or point of trade, which will diminiſh the difficulties of ſupplying the canal with water, as every ſuch junction of ſummits preſerves the water of two lockages, beſides preſenting ſo many more points at which the canal can be ſupplied with water, from ſprings and rivulets above its level, or where, in leſs favourable ſituations, the ſame can be collected in a lower level to be pumped up. The extremities of the principal ſummit or ſummits being thus nearly ſettled, it will next be inquired, how far it is practicable and adviſable to reduce the height of the ſame by deep-cutting or by tunnelling, or both of them. The adviſable height of the ſummit-level of the canal being ſettled, if water is not in ſufficient plenty, a minute ſurvey of both ſides of the range, or ridge which is to be paſſed, and of all its connecting heights, for a conſiderable diſtance on each ſide of the line, ſhould be made by tracing the propoſed ſummit-level along all the ſides of the hills, particularly noting all the ſprings or rivulets which riſe above and croſs this line; and all ſuch ſtreams of water ſhould be accurately gauged, and the quantity of water which they diſcharge per day determined; the ſame ſhould alſo be done for all the rivulets or ſmall ſtreams that croſs the line of the canal throughout its courſe; and theſe experiments ſhould be made not only where the ſtreams croſs the line, or levels, but at a conſiderable diſtance above and alſo below thoſe points, the particulars of which experiments ſhould be regularly and formally entered in a book, with all the attendant circumſtances, and ſigned by the parties preſent at the making of them; as the ſame may prove of the moſt important uſe in future, either for detecting any ſecret leaks in the canal, or feeders by which any of theſe ſtreams may be increaſed; or, in caſe of future claims being made for the water, or the diminution thereof by mill-owners or others, the company may be prepared, either to make a juſt retribution, or to reſiſt ill-founded or ignorant claims with effect. For calculating the quantity of water diſcharged through gauges or apertures of different kinds and dimenſions, theorems ſhould be uſed which make the neceſſary allowance (deduced from experiment) for the form of the channels or apertures; ſuch will be found in Dr. *Young*'s abſtract of M. *Eytelwein*'s learned German work on Hydraulics, printed in the Journals of the Royal Inſtitution, as alſo in *Nicholſon*'s *Journal,* 8vo. iii. 25. The ſurvey of the ſummit of which we were ſpeaking, ought to be accompanied by a plan, on which ſhould be laid down the exact courſe of every valley and range of hill above the level of the propoſed ſummit, with every particular of the nature of the ſoil in each; that in caſe reſervoirs therein ſhould be found neceſſary to collect rain or ſpring water, the neceſſary extent and probable ſupply of ſuch can readily be determined at a ſubſequent period. From one end of the propoſed ſummit-level it will be right now to proceed with the ſurvey, tracing the level accurately and marking the ſame by pegs or ſtakes, that will laſt for ſome time, and be known by the ſurveyor, who is to follow and make a plan of the line; the levels being frequently transferred to what are called bench-marks, upon the trunk of a tree, a large poſt, or a building, the ſame being noted ſo particularly in the field or ſurvey-book, that they may be readily found for years afterwards. We ſuppoſe the engineers, by this time, to have ſettled the riſe that each lock ſhould have, according to the dimenſions adopted for the canal, the probable ſupply of water on the ſummit, and other circumſtances; the ſummit-level will be traced as above, till the proper place occurs for making a fall of two or more locks, at about 100 yards or a little more from each other; and the places of theſe falls being marked, the level is again to be purſued and traced from the bottom of them, and marked out as before, till the opportunity occurs for another pair or more of locks, or till ſome obſtacle, as a gentleman's park, houſes, gardens, orchards, mills, roads, &c. preſent themſelves at a diſtance; when it will be proper, after referring the level arrived at, to a proper and permanent mark, to proceed forwards, and to examine and well conſider the different ways and levels, if more than one of ſuch preſent themſelves, by which the obſtacle can be paſſed. From the moſt confined part of the courſe for the canal, owing to the obſtacle, it will be right to level back, till the former work is met, and, in many inſtances, conſiderably overlapped, in order to determine the moſt eligible mode of bringing the two levels together, upon the principles before ſtated, if they can be applied, either by adding another lock, or taking one from any of the ſets of them which had been before marked out, as occaſion may require, and marking out the new levels thereby occaſioned: the line between the ſummit and the firſt obſtacle, or confined part of the courſe, being thus adjuſted, a new point of departure is to be taken from ſuch obſtacle, and the level purſued as before, till the fall for a pair or more of locks can be gained, at the proper diſtance from each other. It is probable, that but few ſets of locks can thus be determined upon before ſome new, and perhaps more formidable obſtacle will preſent itſelf, which it will be neceſſary to break off for, and proceed forwards to conſider, and to obviate as before; or the new difficulty may conſiſt of ſome conſiderable lateral valley coming into the one which we are ſuppoſed to be purſuing, which may occaſion an inſurmountable or unadviſable length of embankment and aqueducts neceſſary, in order to paſs it; or ſome gentleman's ſeat, mill, or town, may be found ſo completely occupying that ſide of the valley down which the line was proceeding; that the engineer may find it neceſſary to go back and reviſe a great deal of what he had done, perhaps quite up to the ſummit, and perhaps to take a new courſe down the other, or oppoſite ſide of the valley, or at leaſt to determine where, with the leaſt expence of embankment and aqueducts, the valley can be croſſed to gain the oppoſite ſide. The places of the different ſets of locks, or of ſingle ones, if they cannot be avoided, and the line between each being adjuſted anew, we will ſuppoſe the work again to proceed, till ſome new obſtacle preſents itſelf; this may be either a total change in the courſe of the valley that the line was purſuing, ſo as to render it neceſſary to begin to mount ſome other valley towards a new ſummit; or ſome gentleman's park, who is adverſe to the meaſure, may ſo completely occupy the valley, down which the engineer is intent ſtill upon purſuing his courſe, that it may be neceſſary to ſearch out for the moſt eligible place for tunnelling through the hill into ſome adjacent valley, which is about to fall into the main valley. An inſtance of this latter kind occurred at King's Langley upon the *Grand Junction* canal, where the firſt Act provided for a tunnel of near half a mile in length, in order to avoid Caſhiobury park: but the ſame has ſince been altered, and the courſe of the canal continued through this and ſome other parks, contributing not leſs to them in point of ornament than to the public in utility. It may happen, in caſe of a change of the direction of the valley, rendering it neceſſary to leave it, that ſome other valley may be at no great diſtance, into which the canal muſt be conveyed by a tunnel; and in order to render this practicable, it may be neceſſary to go back, and conduct a good deal of the line that had been done upon a new and much higher level, by omitting ſome of the locks, in order that the level may be conducted through, and ſupply the propoſed tunnel: in accompliſhing this, the former obſtacles may recur again, or new and more formidable ones may be preſented. In this way, the patience, perſeverance, and abilities of the engineer muſt be exerciſed, until a practicable line of ſome length is obtained, and ſtaked out; when the aſſiſtant land ſurveyor muſt follow, and make a correct and particular plan of the line of the ſeveral propoſed locks, embankments, tunnels, &c. upon the ſame, and of the ſeveral fields or pieces of land through which it paſſes, or that come within 100 or 150 yards of it in any part: it will likewiſe be the buſineſs of the ſurveyor to aſcertain, with the utmoſt care, the boundary of every pariſh and townſhip, what county each is in, the proper names of the owners and occupiers of every piece of land in each, however ſmall, upon or within that diſtance of the line, with reference to the ſame upon his plan; and to deſcribe correctly all public and private roads and paths that croſs or interſect the line, and to and from what places they lead; the courſe of all brooks or ſtreams of water, and particularly ſuch as lead to, and contribute to the ſupply of any mill: the ſituation of the houſes and towns upon the line, or within ſome miles of it, ſhould alſo be determined; the nearer they are the greater accuracy will be neceſſary. We will now ſuppoſe the engineer proceeding with the line, from the end of a tunnel into a new valley, the courſe of which downwards is in the proper direction; the ſame proceſs is to be repeated as was purſued in deſcending from the firſt ſummit, until this new valley changes its direction, or until ſome great town or work has been reached, and it becomes neceſſary to change the courſe of the canal, and begin to aſcend ſome new valley or plain towards a new ſummit, or towards ſome mine or work, at which the canal is to terminate: to the new ſummit it will be neceſſary to proceed, and after ſettling the height of the ſummit-level, and taking all the preparatory ſteps for aſcertaining the ſupply of water, and other circumſtances of this ſummit, as deſcribed reſpecting the firſt, the levels will be traced from this ſummit downwards, working backwards or up again, as often as obſtacles may render it neceſſary, until the former work in the valley is met, and a proper junction of them contrived: the whole of this part being adjuſted, the ſurveyor may proceed as before, with his plan and particulars: while we ſuppoſe the engineer returned to the firſt ſummit, and from which he will conduct his line, and avoid the obſtacles thereon, in the beſt way that his ingenuity can ſuggeſt, until he arrives at the navigation or ſea-port, at which his canal is to terminate, and where baſons or docks, more or leſs capacious, according to the expected trade, and wharfs, cranes, and other conveniences, may want planning, for the accommodation of the traders and the public: all which the ſurveyor will proceed to ſurvey and plan, as before mentioned. It may be neceſſary to remark, that every town, mine, or work, which happens to lie higher than the line, and to which a collateral cut is to be carried, muſt be conſidered as a ſeparate ſummit, and proviſion for ſupplying the lockage thereof muſt be made, and ſuch of the examination before deſcribed gone into, as may appear neceſſary; ſuch towns, &c. as lie below the line, and are to have cuts or branches to them, will require water to be let down out of the line to ſupply their lockage; on which accounts, it is highly deſirable, whenever the ſame is practicable, to conduct the line upon ſuch a level, that the collateral cuts may be upon the ſame level, by which the trade thereon is much facilitated, and leſs water required.

A complete plan of the line, and all the projected collateral cuts, feeders, reſervoirs, &c. being finiſhed, the engineer will enter on a moſt careful reviſal of the whole ſcheme, with this plan in his hand; on which all the places where culverts or drains will be required, are to be marked, as alſo the proper places for the bridges, and the neceſſary alterations of the roads and paths, which will be cut off by the canal, ſo that the public may not be inconvenienced and turned long diſtances round about, and ſtill, that as few bridges as poſſible, and thoſe in the leaſt expenſive places, may be erected. In ſome inſtances new channels will require to be cut for brooks and water-courſes, to a conſiderable extent, in order to ſave culverts, or bring them to the moſt deſirable ſpots. For proper ſecurity againſt accidental errors, the whole of the levelling ſhould now be gone over again, and the ſeveral bench-marks compared, and renewed with the utmoſt care by the engineer's aſſiſtants, while he is proceeding with the neceſſary inquiries and calculations, for an eſtimate of the whole expence of the undertaking.

In a great number of inſtances it will be found, that the ſupplying of a canal with water, occaſions no inconſiderable ſhare of the whole expence, either in the firſt coſt of mills or ſtreams of water, in land for, and labour in, conſtructing reſervoirs, engines to pump up water, &c.; or annually ever afterwards, in the fuel for, and repairing of, engines, hire of water from mills in dry ſeaſons, &c.; this ſubject ſhould, therefore, employ the moſt ſedulous attention of the engineer, both to make the moſt economical uſe of what ſtreams he finds, to procure other ſupplies of water at the leaſt expence, but above all, to ſecure an abundant ſufficiency. The dimenſions and height of the locks, and breadth of the canal being ſettled, an accurate calculation made of the quantity of water required to fill a lock; and, with the largeſt probable number of boats that will paſs in a day, the quantity required daily in every part of the canal; this, with a due allowance for the evaporation, from the ſurface of the whole canal and its reſervoirs, and for the ſoakage that will take place into the banks, however well they are conſtructed; will ſhow the number of locks full of water that will be required, from all the different ſources. We have ſpoken of the ſteps proper to be taken for aſcertaining the whole ſupply that can be had above the ſummit's level; and it will often be neceſſary to make a ſimilar inveſtigation, on points below that level, and to conſtruct reſervoirs in ſuch ſituations, to ſupply the neceſſary lockage, for local trade upon the line, near any great town or works, which does not extend to the ſummit, as alſo to ſupply the evaporation and ſoakage of long lengths, in ſituations where feeders or ſprings cannot be taken in by the way; another uſe of reſervoirs in leſs elevated ſituations may be, to compenſate mills that are lower down the ſtreams for the water that is taken for the uſe of the canal from the higher branches, or near the ſources of ſuch ſtreams. For Mr. *William Jeſſop's* obſervations on this ſubject we refer to William Pitt's General View of the Agriculture of Staffordſhire, and to the *Repertory*, vol. iii. p. 243.

There appears no reaſon, under the preſent ſtate of things, why the owner of a mill or ſtream of water ſhould not be compellable to part with the ſame, for the purpoſes of a public canal, any more than another man to part with his field, except the accommodation which the public receive from ſuch mill; and where the ſame, or a ſuperior accommodation, can be enſured to the public, ſurely this ſpecies of property ought to be put upon the ſame footing with land in general. See Dr. *James Anderſon*'s Eſſays, vol. iii. p. 68 to 76.

It ought to be conſidered, that the preſent ſtate of our canals and inland navigations, and eſpecially the extenſion of them, which we are now ſuppoſing, remove one of the principal objections to ſteam engines, by enabling new mines of coals to be daily opened, and the products thereof, as well as of the old mines, to be regularly and cheaply conveyed to every ſituation where engines can be wanted. We would not, however, be ſuppoſed to recommend the annihilation of water-mills; on the contrary, it hath long appeared to us, that their number and their power might, in ſome, and perhaps in moſt inſtances, be greatly increaſed, and yet all the purpoſes of canals be fully anſwered, and thoſe moſt capital improvements of irrigation and drainage at the ſame time extended, to very large tracts of land; for this purpoſe it would be neceſſary, that an entire valley of conſiderable extent, that has a good ſtream of water through it, as the *Colne*, or the *Lea* near London, for inſtance, ſhould be put under a ſyſtem of improvement. A thoroughly competent engineer being employed upon ſuch a work, would be able to conduct a canal rather of large dimenſions perhaps, along one ſide of the valley downwards, until three or four locks, or a fall of 20 to 30 feet was obtained; and, the water in the pound below ſuch ſet of locks to be a ſmall diſtance below the level of the ſurface of the ground, in the loweſt part of the valley at that place, as this would enable the whole ſtream of the river to be taken into the next length of level, as often as occaſion ſhould require it: this new level would be traced, until, by the fall of the valley, it has reached the ſides of the hills, and proceeded with until another ſet of locks, three or four in number, can be obtained, and a deſcent made again to the level of the loweſt point of the valley: this proceſs to be continued through the whole length of the valley, under improvement. The next conſideration would be, a deep and effectual drain, to be carried up through the whole length of the valley, purſuing the loweſt ground, and the middle of the valley nearly, in ſuch parts where the hills on each ſide riſe equally abrupt; but where, as often happens, the deſcent to the valley on one ſide is very ſudden and ſteep, and on the other ſide long and gradual; in all ſuch caſes the drain ſhould be conducted nearer to the abrupt than to the eaſy ſide of the vale, becauſe here the peat or alluvial matters, with which ſuch valleys are choaked up, will be found the deepeſt, and the ſprings in the gravel underneath ſuch peat, the moſt copious and the moſt confined; the new drain ought, in general, to reach the gravel under the peat or ſilth; and where this ſhall be found impracticable, large auger holes ought to be bored at ſhort diſtances from each other, quite through the conſolidated peat and ſilth, to the gravel, to ſet the confined ſprings therein at liberty. Theſe principles of draining a boggy valley we have ſeen ſucceſsfully practiſed in the village of Crawley, below Wooburn in Bedfordſhire, by an agent of the late worthy *duke of Bedford*.

If the fall in the new drain ſhould be found very conſiderable, the ſame muſt be reduced, by placing weirs or well-falls at proper places, to let the ſtream down in an harmleſs manner, which would otherwiſe diſplace the gravel and ſand under the peat, and the ſame would cave in, ſo as to fill up and deſtroy the drain: another excellent uſe of theſe well-falls or weirs will be, to furniſh ſo many points, where the whole ſtream, including the ſprings, can be taken out to ſupply the upper end of the levels of the canal before mentioned, or for the purpoſes of irrigation; as was intended and provided for, in the Crawley vale that we have been ſpeaking of. To all the exiſting mills, which are not too ruinous or badly conſtructed to be worth improving, the channels to the water-wheels ſhould be deepened up from the main drain, or, perhaps, in moſt inſtances, new and more direct ones cut. It will now be practicable for the engineer, in moſt, if not in all caſes, to conſtruct an *over-ſhot* water-wheel upon the ſame axis that before carried an *under-ſhot* one, turning the ſame way and with the ſame velocity as before, ſo that the internal machinery of the mill will need no alteration; and the requiſite quantity of water for working theſe new wheels, which in moſt caſes will be inconſiderable, may be conveyed from the canal on the ſide of the adjoining hill, in aqueducts or elevated troughs of no very expenſive conſtruction, perhaps of caſt iron, or in pipes, which may be conducted under ground, and riſe up to ſmall reſervoirs or pen-troughs above the wheels. As many of the mills will be found ſituated on the oppoſite ſide of the vale from the canal, it may be proper and adviſable in moſt caſes, to conſtruct a cut or water-carriage of ſufficient dimenſions, and with a very ſlight fall, along that other ſide of the vale, beginning frequently at the weirs or well falls in the main drain or new brook, and purſuing the level nearly, as far as is found requiſite; which cuts will much extend the benefits of irrigation, and give opportunities, perhaps, of conſtructing new mills, with over-ſhot wheels of large diameters and proportionate power, to be ſupplied therefrom. In like manner, ſeveral new and powerful over-ſhot mills may perhaps be conſtructed near to the ſeveral ſets of locks upon the canal, without endangering the ſufficiency of water for the lockage: this practice of uniting navigation and mill improvements at the ſame time, we were much pleaſed to ſee enforced by Mr. *Thomas Telford*, in his Report of 1801, printed by order of parliament, upon the intended *Inverneſs and Fort William* canal, p. 46: and the ſame has been ſuggeſted as an appendage to the Woolverton embankment on the *Grand Junction* canal; ſee the *Agricultural Magazine*, vol. viii. p. 24. New and improved mills may often be conſtructed where the point of a hill at a great and ſudden bend of the river can be tunnelled through, from the river on the upper ſide, as appears to have been done at Shrewſbury on the *Severn*, and at Stanley on the *Tay* rivers.

Where the new drain or brook courſe connects with the levels of the canal in the improvement of a valley, as above propoſed, if floods are to be apprehended, or the water is ever found very thick and muddy, weirs or over-falls ſufficiently large to let the flood eſcape down the drain muſt be conſtructed, and ſtop-planks provided to be put down acroſs the canal occaſionally, or a lock capable of a very ſmall fall conſtructed, to be occaſionally uſed, to prevent very muddy waters from entering the canal to ſilt it up. It will frequently happen, that brooks which are making their way laterally into a valley under improvement, may by an alteration of their channel for ſome diſtance up the collateral valley, be brought into the canal in places where a conſiderable elevation on the ſide of the hill has been attained, in ſuch caſes a circular weir or well-fall ſhould be conſtructed in the centre of an enlarged part of the brook, before it arrives at the canal, as has been done by Mr. *James Brindley*, at the mouth of Medlock brook at Mancheſter, on *Bridgewater*'s canal; a proviſion for ſtop-planks, at the junction with the canal, will alſo be proper, to be enabled to turn occaſional muddy water down the well-fall inſtead of into the canal. In order to preſerve a ſufficient elevation in the water-courſe, for ſupplying of mills, or for irrigation, after the canal has deſcended a ſet of locks, and is conſequently too low for this purpoſe, a cut or water-carriage may be taken out of the ſummit's level, and carried on along the ſide of the hill with a proper fall, as far as may be neceſſary. This ſyſtem of improvement in a valley, is capable of being combined with an extenſive application of reſervoirs, for equalizing the head and collateral ſtreams which ſupply ſuch valley, as recommended by Mr. *W. Jeſſop*.

In caſes where the land or park owners cannot be brought to concur in a general ſyſtem of improving a valley, it would often be worth while for a canal company to obtain power from the legiſlature to purchaſe all or moſt of the mills in a valley, through which their canal is to paſs, paying, in the firſt inſtance, the utmoſt value for them; and being alſo bound to erect the ſame number of mills, of equal or ſuperior power, and adapted to the ſame purpoſes, to be ſupplied from higher levels in the manner we have been deſcribing; ſuch new mills to be offered at a fair price, to be ſettled by indifferent perſons, to the owners of the adjoining old mills, before the ſame are diſturbed in the uſe of the old mills, and in caſe of their refuſal to purchaſe, the ſame to be next offered to the perſons who may be tenants to the old mills (in order that they may not be thrown out of employ); and then to any other perſons inclined to become purchaſers, on ſuch terms as they and the canal company could agree upon.

Sometimes it may be practicable to make a bargain for taking weekly into the canal, a ſtream of water which ſupplies a mill, only from Saturday night to Sunday night, paying a fixed rent for the ſame, to be ſecured by the act; an inſtance of which occurs upon the *Montgomery* canal.

The ſubject of ſupplying water for a canal having been amply illuſtrated, we ſhall now return to the reviſal of the ſurvey, and making an eſtimate of the expence of the undertaking, on which we ſuppoſed our engineer to be employed. In reviſing the ſurvey of the line, it may be proper for the engineer to cauſe holes to be dug at certain diſtances, as deep as the canal will require to be cut, or deeper, to inform himſelf more perfectly of the ſoil to be cut in, and the expence attending the ſame, noting particularly the height to which ſprings may riſe in the ſeveral holes. And here it may be proper to notice a very common error, into which the perſons entruſted to execute canals have fallen, in ſuch parts where ſprings appeared beneath the ſurface in the cutting, by concluding that the canal would make water, as they term it, in ſuch parts, and that puddling was unneceſſary; but where too often it has afterwards happened, that ſuch ſprings, from having a variety of other vents or outlets, at or very near to the ſame level, and were, therefore, incapable of being dammed or raiſed much higher than they then appeared; when the canal has come to be filled with water to a higher level, the courſe of ſuch ſprings has been reverſed, and the porous ſtrata through which they paſſed have ſerved to abſorb and diſcharge the water at other places, to a very fatal extent. Land-ſprings, or ſuch as run only in winter, have generally the ſame effect, and in ſummer as copiouſly take in water, when their own ſource fails, as they before diſcharged it. The difficulty of puddling or lining out ſprings, on account of the powerful effort they make to force their way through the lining, as long as the canal remains empty at firſt of water, will induce a careful engineer, to endeavour to avoid, if practicable, all ſprings that will not at all times riſe to a higher level than the water is to ſtand in his canal. It will be part of the buſineſs of this reviſal of the line, to examine what can be done to ſtraighten the canal, we mean as to ſudden bends, by ſmall lengths of deep-cutting, and others of embankment, to correct the plan accordingly, and to eſtimate the extra expence of all ſuch works. The lengths and ſolid contents of the ſeveral embankments, and the diſtance from which the ſtuff or ſoil muſt be fetched for the ſame; the lengths and dimenſions of all the deep-cuttings, and the diſtance to which the ſtuff muſt be removed; the lengths of the tunnels, and number and depths of the ſeveral ſhafts or tunnel-pits that will be neceſſary; the lengths of headings or ſoughs that will be wanted to drain the tunnelling works; theſe, and all the great variety of other works, ſome of which we have already mentioned, and others that we ſhall have occaſion to mention in the ſequel, being particularly ſtated, and prices affixed to each ſpecies of work and kind of material; and theſe prices ought by no means to be below the current prices of the beſt articles of the kind at the time, but due allowance ſhould alſo be made for the advance of prices, which will take place during the execution of the work. The total probable expence, with a due allowance for contingencies, being thus obtained, the engineer will prepare his general report and eſtimate, to be laid, with the plan, before a meeting of the adventurers or propoſed proprietors.

The next ſtep in the progreſs of this buſineſs, after the appointment of a ſolicitor of competent legal knowledge, is an application to parliament for an act, empowering the parties concerned to complete their undertaking.

From the earlieſt times, the parliaments of this country have found it neceſſary to adopt certain ſtanding-orders, or general rules, to be obſerved by the parties who applied for any act of a local or private nature; and theſe ſeem to have guided the conduct of canal projectors, till the number and variety of ſuch applications ſhewed the neceſſity of adopting, on the 7th of May 1794, thirteen ſpecial reſolutions, as ſtanding orders, relating to the introduction and paſſing through the houſe of commons, of any acts for navigable canals, or aqueducts, or for the navigation of rivers; to theſe another was added on the 16th June 1795, reſpecting intended reſervoirs and feeders to a canal or navigation; and another on the 25th June 1799, applying the former orders to rail-ways or drain-roads, as far as the ſame are applicable. The houſe of lords have a nearly ſimilar ſet of ſtanding orders, and one requiring a ſufficient number of copies of an engraved map of the intended canal, &c. to be delivered for the uſe of each member of that houſe.

The number of clauſes, relating to the conſtruction and management of a canal, are neceſſarily very numerous, and it were much to be wiſhed, that the propoſition of Mr. *John Clennel*, in ſeveral periodical works, for a general canal act, to contain all their general clauſes and proviſions, in the ſame way as the general highway and turnpike acts, and the general incloſure act, could be accompliſhed; it would much ſhorten and ſimplify the buſineſs of canal acts and management. Another general meaſure, relating to canals, we beg here to mention, although the application to parliament in the ſeſſion juſt now paſſed (1805) did not prove ſucceſsful, we mean the propoſal for a *general canal company*, for raiſing a large fund, to be inveſted in ſhares of canals not yet finiſhed, and for lending money at intereſt, to ſuch canal companies as may require it, to enable them to complete and render their ſeveral concerns more generally beneficial.

Mr. *William Chapman*, when ſpeaking of the navigations of America, ſays, (Obſervations, p. 64.) "It will be adviſable in a riſing country, to lay out the lines of canals approximately on its firſt ſettlement; reſerving a proper width for them, in the original grant of the lands, with power to exchange the land of that line, for any other found more convenient, on a full inveſtigation; and thus avoid all the difficulties attendant on thoſe meaſures in England." Does not the period of the incloſure of a pariſh here furniſh the ſame opportunity of conſidering the eligible line for a canal; and of ſo contriving the allotments that very few, or perhaps only one perſon's land may require to be cut into, upon the adoption of ſuch meaſures, and that without cutting up or deranging the ſyſtem of his or their eſtate? We were happy to ſee this idea acted upon, as far as irrigation is concerned, in the pariſh of Maulden, in Houghton-Regis near Dunſtable, (into which a cut from the *Grand Junction* canal was propoſed to be brought,) and in ſome other pariſhes in Bedfordſhire, about the year 1797, by the late duke of Bedford's agent.

One of the firſt objects of a canal act is, to incorporate and make a body politic of the proprietors, by a certain *name* and ſtyle, by which they ſhall have perpetual ſucceſſion and a common ſeal, and by which they may ſue and be ſued, and have power to purchaſe lands, to them, their *ſucceſſors*, and aſſigns, for the uſe of the undertaking, without incurring the penalties and forfeitures of the ſtatutes of mortmain; and to enable the company to ſell any lands ſo purchaſed. The ſelection of the name for a canal, is of more conſequence than would at firſt ſight appear. Since canal and rail-way companies have multiplied ſo very much, it is neceſſary on all occaſions to adhere to and uſe their incorporate or *parliamentary names*, a circumſtance which has not been attended to ſufficiently, but ſuch a variety of names have been uſed, in the printed accounts of events upon or relating to our canals, that it is often impoſſible to avoid miſtakes.

It has been uſual to enable the company to raiſe a fixed ſum of money, equal to or exceeding the total eſtimate of expences, by ſubſcription or ſhares; and, in caſe of this proving inadequate, to borrow a further fixed ſum upon intereſt, or on mortgage of the tolls. The many and expenſive acts of parliament that canal companies have been obliged to obtain in the courſe of their work, for powers to raiſe further ſums, and even for regulating and enforcing the mode of raiſing the ſums firſt authoriſed, ſhew the neceſſity of the engineer and ſolicitor paying great attention to this point, and to be careful to apply for powers ſufficiently ample.

The uſual amount of ſhares in canal companies is 100l. but inſtances of 50l. ſhares, and others of leſs or greater value, occur in ſeveral of theſe eſtabliſhments. Theſe circumſtances ought always to be particularly attended to in comparing or quoting the prices of ſhares in different concerns; and we ſtrongly recommend all future ſhares to be 100l. ones, eſpecially as the legiſlature will permit of half ſhares, or even lower diviſions, down to the eighth of a ſhare, as appears in the *Grand Junction* act, 43 Geo. III.

To prevent the intereſt of any individuals from preponderating, and to increaſe the number of perſons having an intereſt in the ſucceſs of the undertaking, it has been uſual to limit the number of ſhares which any individual can hold, under forfeiture of all above that number, except they came to him or her by will, marriage, or other legal proceſs.

The election of a committee of management, and all queſtions agitated in the company are decided by votes, not perſonally, but according to the number of ſhares held by each perſon, to a limited extent, and uſually two half ſhares carry one vote. The uſual limitation to prevent any individuals from poſſeſſing too great power in the company is, that no more than 15, or ſometimes 20 votes ſhall be given by one perſon; while in the *Newcaſtle-under-Line* only 6 votes are allowed; and in the *Croydon*, *Peak foreſt*, and *Thames and Medway*, no more than 5 votes can be given by any one proprietor.

General meetings of all the proprietors are provided for, on any important occaſion, as well as annually to elect the committee and officers.

Proviſion ſhould be made for progreſſive calls on the proprietors, by the committee, for their ſeveral ſubſcriptions; theſe ſhould be on as long notice as is eligible; but they muſt be prompt and ſtrictly enforced, or the progreſs of the works will ſuffer.

The enactments relating to purchaſing of lands, and aſcertaining the value thereof, where the parties and the company's ſervants do not agree, by means of the commiſſioners, will be neceſſary, who generally conſiſt of all the conſiderable land-owners of the county, or of a jury to be impannelled for ſuch purpoſe, theſe ought to be very clear and explicit: ſo ſhould the regulations and forms for ſelling and transferring ſhares in the concern.

The moſt ample powers ſhould be given to enter upon, and dig, and conſtruct, both the permanent and all temporary works which may be neceſſary; with proviſions, in caſe of refuſal, to accept the compenſation offered for damage; that the commiſſioners or a jury ſhall ſettle the ſame without delay or further appeal, except, in ſome inſtances, to the next quarter-ſeſſion of the county.

A clauſe is generally inſerted, confining the company to the line that is laid down in the plans that have been depoſited with the clerk of the peace and with the houſe of commons, or within certain limits on each ſide thereof; the uſual deviation diſtance allowed is 100 yards; however, many inſtances have occurred, which ſhew how very important it is to the proprietors, that the line of the canal, and every probable cauſe for the neceſſity of deviation, ſhould have been thoroughly examined and weighed by the engineer, and the line ultimately adjuſted, before the plans are completed and delivered.

The prudent precaution of the legiſlature, has always limited the width of land which canal proprietors have been empowered to purchaſe for their canal, in ordinary caſes, without the free conſent of the owners; this has been 26 and 30 yards, in the greater number of inſtances, but in others the ſpace allowed for the canal towing-path and fences has been leſs or greater, according to circumſtances.

Where wharfs, docks, or baſons, or places for barges to turn and paſs each other, or where deep-cutting or embankments are required, it has been uſual to allow 100 yards in width to be purchaſed; but from this allowance there have been occaſional deviations.

Except in ſome rare and peculiar inſtances, like the *London Docks* in Wapping, the parliament will not give to any company the power of purchaſing houſes or other buildings, gardens, orchards, yards, parks, paddocks, or planted walks or avenues leading to any houſe, except the previous conſent of the owners thereof be obtained; and where this has been got, it is the ſafeſt way to inſert a liſt of all ſuch owners, with a deſcription of the property they have agreed to give up, as a ſchedule to the bill: and the ſame of all material contracts for mills, ſtreams of water, or ſprings, which the company may have made. Houſes built, or orchards, &c. made as obſtructions, ſince the ſurvey was made, and notices given, will not meet with the ſame protection; and a clauſe ought to be inſerted to put them upon the ſame footing with lands in general.

Powers ſhould be given for erecting public wharfs, and for demanding and enforcing certain equitable rates of wharfage for goods, according to the length of their continuance on the company's premiſes.

The toll, or rates of tonnage, which the traders are to pay to the company per ton per mile for the liberty of navigating upon the canal, or its various branches, rail-ways, or inclined planes, require the moſt deliberate conſideration, that every ſpecies of trade may pay its proportion, and none be diſcouraged or leſſened by the expences of conveyance.

In ſome caſes proviſion has been made, that when the net profits of the concern exceed a certain rate per cent. the tonnage or tolls ſhould be reduced.

There have been exemptions from tolls, on ſeveral canals, in favour of officers and ſoldiers on their march, with their horſes, arms, and baggage. Timber for the uſe of his majeſty's navy, and government ſtores of all kinds ſometimes paſs toll free; ſo do gravel or other materials for the making or repair of roads in moſt inſtances. In ſome caſes, canals have been projected principally with a view to tonnage on lime, and other manures and agricultural objects and produce; but with this exception, it has been uſual to allow lime and all manures to paſs, either on very low tonnage, or abſolutely toll free, on the levels, and through the locks alſo on ſome, particularly when the water actually runs over, or is within a quarter or half an inch of the top of the lock-weirs; in ſome inſtances, ſeveral hours notice is required, of boats with manure or road-materials intending to paſs any locks toll-free. In ſome inſtances, where a canal is to run parallel to a turnpike road, and is expected to leſſen the tolls thereof, by the diminution of heavy waggons and carts, it has been uſual to compenſate or indemnify the creditors on ſuch roads; and it ſeems equally juſt, where a turnpike road croſſes a canal, and is likely to have its tolls both ways increaſed, that they ſhould not be entitled to receive materials by the canal tonnage free.

Mile-ſtones are directed to be fixed on banks of moſt canals, for regulating the diſtances and tonnage; in ſeveral inſtances, theſe are directed to be placed every half mile, and in others one is to be placed at the end of every quarter of a mile.

We ſhould far exceed our due limits, if we were minutely to recount the various expedients that have been adopted for conciliating the owners of lands, parks, mills, &c. who may more or leſs be affected by different canals. Theſe muſt depend on a variety of local and incidental circumſtances, for the adjuſtment of which no general rules can be preſcribed. But in all caſes of this kind the canal companies have uſually propoſed, and the legiſlature has ſanctioned, an adequate compenſation. Proprietors of land and their tenants are ſometimes allowed the uſe of the towing-path, as a drift and bridle-way between their different lands, or to ſome public road; the owners of the adjoining lands are often allowed to make, not only docks and baſons communicating with the canal, but collateral cuts of conſiderable extent, to their mines and other works; but previous notice of all ſuch intentions ought to be given to the company, that their engineer may examine the ground, and direct the neceſſary puddling and other precautions, to ſecure the line of canal from loſing water to a prejudicial extent thereby.

The company are often empowered, and ſometimes required, to make collateral cuts, or rail-way branches to particular towns, mines, or works; and a very proper precaution ſeems to have been adopted in the *Somerſet Coal* canal act, that the parties to be benefited by ſuch branches ſhould firſt give the company ſecurity to make up the tolls thereof, by an annual payment, in caſe of their falling ſhort of a reaſonable intereſt on the money expended upon ſuch branches.

In ſome inſtances it may be neceſſary, particularly on railways, to permit individuals to conſtruct and manage ſuch part of the works as paſs through their own park or ground, but ſubject to the general ſyſtem of management laid down in the act; as is done by the *duke of Beaufort* on the *Swanſea* canal, and by *ſir Charles Morgan* on the *Sirhowy* tram-road; alſo to conſtruct particular parts, on being paid for the ſame, as was done by the *Dee* river company, at the croſſing of the *Elleſmere* canal.

Clauſes are generally inſerted, requiring the canal company to remove and clamp the top ſoil, or vegetable mould, to the depth of nine inches, from the whole width of the intended works; which, after the ſame has been completed, and all the banks and excavations properly ſloped down, is to be returned and ſpread upon them, ſo as to render all the land, not actually occupied by the canal and works, capable of cultivation; but a ſmall part of this top ſoil is wanted in general upon the banks, and it might, more profitably for all parties, be filled by the company's men into the carts of the neighbouring farmers, to be ſpread upon the poorer parts of their lands.

*Watering places* for cattle are generally directed to be made, eſpecially where the fields may have been deprived of their old ones by the cutting of their canal. In counties where irrigation is much practiſed, as in Wiltſhire and ſome others, it has been common to appoint ſkilful and reputable perſons to guard the intereſts of the irrigators, on the cutting of canals.

On the duke of *Bridgewater*'s canal, irrigation trunks were laid below the bottom of the canal, ſo that, by means of a harrow, or rather a large hoe, drawn along, the mud of the canal was drawn to the valve or orifice of the trunk when open, and the mud was thus conveyed to the meadows bebelow. A ſucceſsful experiment was here alſo made, of bringing up barges laden with ſea fluſh, or mud taken up at low water, in the Merſey, and this was gradually poured or thrown out into the canal, over the irrigation trunks while running, by which means this valuable manure was at once conveyed to and effectually ſpread on the meadows below. We have been greatly ſurpriſed to find irrigation ſo little practiſed upon the lands below canals, which ſo perfectly admit of that improvement; were this ſubject properly attended to, in ſituations where water is plenty, we doubt not but ſome proprietors or leſſees of land would be found, who would readily contract with the engineer, on the part of the company, before the canal is completed, to pay an annual rent for certain quantities of water, to be let out by the company's agents, at ſtated times, through a trunk, which might be laid beneath, or level with the bottom of the canal for ſuch purpoſe, at a very eaſy expence, before the water was let into the canal; and even after canals are completed, there are ſituations where the intereſt of all parties might be ſerved, by laying trunks for irrigation; and perhaps farmers ought not, except in ſome few inſtances, to be debarred from conſtructing or uſing proper weirs at the ſame immoveable height, or a little higher than thoſe at the lock-gates, to take off the ſurplus water for irrigating during the winter ſeaſon.

Sometimes it will happen that a canal can be conducted on a proper level to ſuit the adits to mines, as at Worſley on *Bridgewater*'s canal, and ſome others; or perhaps the tunnel through a hill may be applicable to mining purpoſes alſo, as at Morwelham down, on the *Taviſtock*, near Ripley on the *Cromford*, the Harcaſtle tunnel on the *Trent and Merſey*, and others.

Coal-mines may be allowed to have the neceſſary paſſages for their works under a canal, but ſhould be reſtricted in the number, width, and height of theſe, as on the old *Birmingham* canal; or if the veins are near the ſurface, the ground may be ſo entirely broke in, that the canal would be deſtroyed, as has actually happened on ſome of the branches of the above-mentioned canal, near to Wedneſbury.

Reſpecting mills, it may be neceſſary ſometimes, where the canal is to be conducted near to eſtabliſhed mills, that they ſhould be ſecured againſt other mills in the ſame line of buſineſs being erected on the canal at that place, as in the *Sankey* canal act. Sometimes gauge-weirs, or ſelf-regulating ſluices, may be neceſſary to be maintained, to ſupply mills or other canals with a regular and conſtant quantity of water; inſtances of which occur on the *Rochdale* canal, and at the Amſworth reſervoir, on the *Nottingham* canal; the theory of the regulating ſluice, in the latter place, will be found in the *Gentleman's Diary*, 1799, p. 43. by that eminent mathematician and coal-worker, Mr. *Thomas Walker*, of Bilborough; and if theorems for the widths and heights of ſluices to diſcharge given quantities of water per day be wanted, *Nicholſon's Journal*, 8vo. vol. iii. p. 29. and 34. may be conſulted with advantage. Thoſe who may wiſh to ſee how the ingenuity of mill-owners can be exerciſed to ſecure themſelves againſt poſſible injury, or even to thwart a canal ſcheme, may perhaps conſult the *Croydon* canal act, for the clauſes relating to the Wandle river.

Where a connection is to be made with any other canal lying upon a higher level, or even the ſame level, where leakage or waſte of water is to be apprehended, that would be prejudicial to either of the canals, it is uſual to provide, that a ſtop-gate ſhall be erected at or near the junction, which one or both of the canal companies are empowered to ſhut and lock up whenever there is ſuch a lowering or draught of water upon one of the canals, as would endanger the ſupply or lower the head of the other; clauſes for theſe purpoſes will be found in the *Dearne and Dove*, *Dudley*, *Stratford*, *Warwick and Birmingham*, *Wyrley and Eſſington*, and other acts. And when any canal joins another, coming down from a hilly country, it is uſual to require tall-gates to be erected, with capacious weirs for preventing of floods from the upper canals making their way into the lower one, as in the *Aberdeen* canal. It will very often happen, that tolls or dues will be to be paid by barges for entering any of the exiſting navigations from the new canal, or *vice verſa*. And where the new ſcheme can be ſuppoſed to interfere materially with the trade on any former one, it has not been unuſual to guarantee that their net profits or tonnage ſhall not be leſs, after the completion of the new canal, than before; or ſometimes annual payments are agreed to be made as compenſations for the expected loſſes to older navigations; and in ſome inſtances, where the rivalſhip is expected to be very formidable, as on the *Douglas River* by the *Leeds and Liverpool*, and the *Derwent River* by the *Derby* canal, proviſion has been made, that the old concern ſhall be purchaſed by the new proprietors at a fixed ſum; the ſettlement of the various compenſations that may be neceſſary on a canal are often ſuch as to require the exertion of the utmoſt abilities of the engineer, with the moſt able aſſiſtance, as the very long and complicated clauſes in many acts will ſhew.

On applying to parliament for any conſiderable extenſion of a canal, or to raiſe more money, there are inſtances, and perhaps very proper ones, of enacting that the ſhares of certain diſcontented proprietors ſhould be purchaſed out of the new funds, as on the *Dudley*, the *Kennet and Avon*, and others.

So attentive has the legiſlature been, even to the comfort of proprietors or inhabitants near intended canals, that it has been enacted, as on the *Barnſley* canal, that where ſteam engines were to be erected in certain places, for the uſe of the canal, their fire-places ſhould be ſo conſtructed as to conſume the ſmoke.

Ample proviſions ſhould be made, for powers to make bye-laws for regulating the trade upon the canal, for the form and dimenſions of the barges or boats to be uſed thereon, and for paſſing the locks, inclined planes, &c. that may be thereon. It is neceſſary to declare, that the canal is not to be ſubject to the interference of the general commiſſion of ſewers; manorial rights, and fiſheries in old ſtreams, or waters ought to be reſerved; and it would be well for the encouragement of theſe great national improvements, if the legiſlature would permit a clauſe to ſtand, as in the older acts for *Bridgewater*'s and other canals, that the proceedings and writings of the company ſhould be valid without ſtamps.

It has been uſual to enact penalties for a variety of offences likely to be committed upon the canal; and for malicious damaging or deſtroying of the works to declare the offenders guilty of felony, and liable to tranſportation for ſeven years. There are many other things which will require to be taken into conſideration at the period of framing the act of parliament, ſome of which we ſhall avoid repetition by mentioning, when ſtating what occurs to us on the practice of executing and managing canals, to which we are now anxious to proceed.

The act of parliament for a canal being paſſed, and therein the time and place for the firſt meeting of the ſubſcribers or proprietors thereof being fixed; one of the firſt buſineſſes of ſuch meeting will be the election of a *general committee of management*, conſiſting of the moſt independent, reſpectable, and generally informed perſons among the proprietors. The committee of management will then proceed to elect a chairman and ſubordinate officers; to fix upon their place of meeting, and to arrange the order of their buſineſs.

It will not often happen that the engineer can be ſpared from the projection and ſuperintendance of other great concerns, to attend to the cutting of the canal and erection of the ſeveral works, without the aſſiſtance of a *reſident engineer*, or more than one, if the line be of conſiderable length, and diſtant parts of it are intended to be proceeded with at the ſame time; and the committee will do well to leave it to their engineer to recommend all ſuch aſſiſtant or reſident engineers from among thoſe who have been brought up or employed under him, or are well known and approved by him, for their mathematical knowledge and practical ſkill, experience and attention in the ſeveral kinds of works that are to be executed. The attention of the committee ſhould be directed to fixing upon ſome *land ſurveyor and valuer* of reſpectability and great practical knowledge, who has been uſed to and acquired addreſs in the negociation and ſettlement of purchaſes and exchanges of property of different kinds; and if he has before been employed upon canals he will be ſo much the more fit. In this ſtage of the buſineſs it may be well alſo for the committee to conſider whether any *local committees*, or a *ſelect committee*, may be neceſſary, to pay the more minute attention to, and to bring before them, the concerns of particular diſtricts of the canal, and to ſerve other purpoſes.

The body of the proprietors, aſſembled in a general meeting for the purpoſe of completing the organization of the affairs of the company, will proceed to the choice of a certain number of auditors of their accounts, and to ſettle the ſalaries of all the perſons that are employed.

Moſt canal acts direct, that two copies of the plan of the canal and book of reference, with any amendments or alterations that may have been made in parliament, are to be certified by the ſignature of the ſpeaker of the houſe of commons; one of which is to be lodged with the clerk of the peace for the county, and the other with the clerk to the company, who are required to produce the ſame, and ſuffer copies or extracts therefrom to be at any time taken by any perſon, and to produce the original before the committee, or any jury who may be called on to decide any matter or diſpute relating to the making or maintaining and uſing of the canal.

The engineer being now informed of the exact bounds within which the law has confined his operations, and of the ſeveral reſtrictions or alterations that may have been impoſed or made ſince his former ſurveys, will, in all probability, find it neceſſary to look over the line and all the propoſed works again, accompanied by the intended reſident engineers; and, in ſuch reviſal, it will be proper to divide the line of canal, and the ſeveral works thereof, into the neceſſary number of parts, and to give conciſe and definite names to each, that are to be uſed in future, in contracts and bills, &c. of which diſtinct parts or diviſions a ſeparate account of the expences ſhould be ſtrictly kept by the reſident engineer, the *overſeers*, or counters as they are generally called, (that the engineer is to recommend or employ upon the works) and by the office-clerks in a ledger, with proper heads for each length of canal, ſet of locks, tunnel, embankment, deep-cutting, reſervoir, aqueduct, or other great work, that may form a ſeparate diviſion: ſuch particular and divided accounts of the works will prove of the moſt eſſential ſervice to the committee, and to all others concerned, in informing and maturing their judgment on the actual or probable expence of every different kind of work; and will enable the committee to account to the proprietors how great, and ſometimes unavoidable, as well as unexpected, expences may be incurred.

The committee ſhould now well conſider and inquire, whether any particular part of the line can be completed and opened with advantage, before the whole length can be got ready; and this being determined upon, the engineer ſhould compare and conſider, from the eſtimates and particulars that he poſſeſſes, the comparative length of time that every particular work upon the length intended to be firſt completed will require; and in this order, or with a proportionate exertion and number of men, ſhould the ſeveral works be entered upon. Immediately after the plan has been ſettled, preparations ſhould be made for providing all neceſſary utenſils and implements.

The Act for a canal ſhould give the company and their ſervants power to enter upon and occupy, for the temporary purpoſes of their works, heaps of ſoil, &c. any land except parks, orchards, and gardens, within the limited diſtance, on condition of their making a full and ample ſatisfaction, by annual rent, to the former occupier or leſſee, and for all damage to the owner and occupier, ſo ſoon as the works are completed, and the heaps, &c. can be removed or levelled down, and covered with ſoil. The tunnels, deep-cuttings, embankments, or other great works, that are firſt to be begun, (and the levels, widths, &c. of which we ſuppoſe to be completely ſettled,) ſhould be now marked upon the ground, with the neceſſary allowance of width for the ſlopes, and the ſpoil-banks, which the engineer may judge right to remain the permanent property of the company.

The land-ſurveyor ſhould now proceed to treat, under the direction of the committee and the engineers, with the ſeveral parties who are entitled to the land that is wanted; for this purpoſe, it will be right for the ſurveyor to prepare correct and explicit plans and admeaſurements of every piece of land, and, in many inſtances, to deliver copies of the ſame to the parties; to conſider well the intrinſic value of the land to the owner, and of any extrinſic or artificial value which it poſſeſſes, with ample allowance for the injury that his remaining property will ſuſtain by being detached, or by the fields being cut into inconvenient and aukward ſhapes, or on any other account.

It is generally provided, in canal acts, that where any perſon's eſtate is cut in two by the canal, and a part, conſiſting of leſs than a certain quantity, is ſevered from the reſt, the company ſhall be compellable to purchaſe ſuch detached part, if the party wiſhes it. And it ought to be provided, that the company are not to be obliged to make an occupation-bridge for leſs than a certain number of acres, unleſs the dwelling-houſe or farm-premiſes of the eſtate happen to ſtand upon ſuch ſmall detached part.

As ſoon as the ſurveyor has made his contracts or ſhort agreements with the parties, containing a full deſcription of the lands or other property to be purchaſed, the ſame will probably be put by the committee into the hands of the clerk to the company, with directions for him to enquire into the nature of the titles of the parties, and prepare conveyances accordingly, in the ſhort and ſummary form that the Act ought to provide for ſuch purpoſe: in like manner, where the parties who own the eſtate could not be come at, or have not been brought to agree by the ſurveyor, he ſhould furniſh the committee with the particulars of ſuch property, the price offered, and other particulars of the negotiation; in order that the clerk may be directed to prepare the neceſſary notices for a meeting of the commiſſioners deſcribed in the act, or a warrant to the ſheriff of the county for empanelling a jury to hear the evidence, who are to be ſummoned on the part of the company, and thoſe produced by the owner of the eſtate, and to view and examine the premiſes if neceſſary, and to give their verdict or aſſeſſment of the ſum that is to be paid by the company, and accepted by the parties.

The ground for the neceſſary reſervoirs, to ſupply the part of the line that is to be begun, ought to be among the firſt that is marked out, including ſpace for the head or new embankment that is to be made, and ſhould be treated for and purchaſed by the ſurveyor, and conveyed as above mentioned. The ground whereon the locks are to be built, or any wharf or walled baſons are to be made, ſhould alſo be carefully aſcertained by the engineer, and purchaſed in an early ſtage of the buſineſs, in order that the ſummer ſeaſons may be fully embraced, for the building of all the maſonry and brick-work.

The modern acts for canals uſually contain a clauſe, requiring all the top-ſoil to be removed. This, of courſe, will be attended to before any of the works are begun.

It has been found, from experience, that the banks of canals againſt which the water is to lie, ought, in general, to have their ſlopes ſo apportioned, that one foot in depth will give a horizontal baſe of one and a half foot; and to theſe or ſome proportions near them, rather above than below, as ſlopes of $1\frac{1}{2}$ to 1 are in general too ſmall, will the widths at top and bottom, and the depth of the intended canal probably be fixed by the engineer: and it has been found convenient and proper to make up the banks of canals one foot higher than the water is intended to ſtand in them.

We are now to ſuppoſe the reſident engineer to be proceeding with the ſetting out of the canal, being furniſhed with a map of the ſeveral fields through which it is to paſs, the line that is proviſionally ſettled for its courſe, but with liberty to deviate within certain limits therefrom, and with bench-marks which the engineer has left and deſcribed at certain diſtances, to regulate the top-water level, or height of the water in the intended canal; and, as above obſerved, one foot higher will be the level of the top-bank, or height of the banks.

It will be proper for this engineer, and we ſhall in future, for the ſake of diſtinction, denominate the other the *principal engineer*, to trace the levels accurately of each pound or level reach of the canal, and to put in level-pegs or ſmall ſtakes, at every two or three chains, more or leſs according as the ground is more or leſs undulating, as he proceeds; wherever the canal is conducted along the ſide of a hill, as will happen in a great portion of its length, the level-pegs are not to be placed exactly along the line that the principal engineer has marked out, but either above or below that line, as the ſlope of the hill may occaſion, exactly at that point in every place, where the level of the top-bank (traced by means of a good ſpirit-level, with teleſcopic ſights) cuts or interſects the ſurface of the hill. In ſome places it will be found that the principal engineer has drawn his line acroſs the point of a hill, ſo as to occaſion deeper cutting than uſual, to avoid going round it; or, on the contrary, croſſed a vale or low place, ſo as to require leſs cutting or perhaps none at all, to avoid taking a circuit up that vale to follow the level of the ground; and if either of theſe deviations ſhould be ſo conſiderable that the level-peg would fall more than two chains or thereabouts from the line, down or up the ſlope of the ground, the plan of having level-pegs upon the ſurface muſt be departed from, and holes ſhould, in the firſt caſe, be dug at proper diſtances in the line, and pegs put into the ſame with their tops to the right height; or, in the ſecond caſe, longer and ſtouter ſtakes ſhould be uſed, particularly in the fences that are croſſed by the line, or other places where they will not be liable to diſturbance, and drove firm into the ground till their tops mark the right level. In tracing theſe levels, the engineer will refer to and compare his work with all the bench-marks before deſcribed, and at each end of a level or reach, will level up and down to the bench-marks of the reach above and below the one he has been working at, and compare the ſame with the fall that the locks at each place are intended to have. And we recommend particularly to the engineer to be very punctual in entering minutely in his field-book the particulars and ſituations of the ſeveral level-pegs, and to make one or more of the men who aſſiſt him in levelling, perfectly acquainted with the ſituations and diſtinguiſhing marks of them, and frequently to cauſe them to be looked over and renewed; or continual repetitions of conſiderable lengths of the work will be neceſſary, owing to the diſturbance and loſs of the pegs by the cultivation of the fields and treading of the cattle, or by the interference of idle and miſchievous perſons of the country. Too much caution cannot ultimately be taken, by frequent reference to the bench-marks, with due allowance for any accidental variation that may have been diſcovered among them, and repetitions of the levelling, to avoid thoſe diſgraceful blunders into which ſome leſs capable and leſs careful engineers have fallen.

We are now to conſider, that the great *deſideratum* in canal digging is, that the ſtuff that is dug from one part of the work, ſhall, with the leaſt labour or diſtance of moving, exactly ſupply or form the banks that are to be raiſed in another; ſo that on the completion of the work, no ſpoil-banks or heaps of uſeleſs ſoil ſhall remain, or any ground be unneceſſarily rendered uſeleſs by excavations or pits. Six different caſes will be found frequently to occur in the cutting or forming of a canal. (*Plate I. Canal, figs.* 1, 2, 3, 4, 5, and 6.) A′A E L P P′ being, in every caſe, the line or ſurface of the ground acroſs the canal; A B C E, in the firſt five caſes, the bank on which the towing-path is to be made, and therefore generally the wideſt; L I K P in *figs.* 1, 2, and 5, the off or ſmaller bank; C I is the top, F G the bottom, and C F and I G the ſloping ſides of the canal, in every caſe. The bench or berm, I K, in *figs.* 3 and 6, is provided to retain and prevent the looſe earth that may moulder down from the upper bank P K from falling into the canal. Sometimes the interference of proprietors, or other cauſes, may occaſion the towing path to occupy the bank, or place of the bench I K, inſtead of B C, which will cauſe a conſiderable difference in the calculation or meaſure of the ſtuff to be moved in *figs.* 2, 3, and 5, but the ſame do not properly form new caſes. The firſt caſe occurs moſt frequently in cutting acroſs or along level meadows, and we were not ſo well able, when treating of the firſt ſurvey or projection of a canal, as we now are, to explain a limitation which ought to be attended to in all ſuch level-cutting, eſpecially if of any conſiderable length, viz. that the height or level of the canal ſhould be ſo contrived, that in any croſs ſection, as *fig.* 1. the ſum of the areas of A B C E and L I K P ſhall juſt be equal to E F G L, the part excavated or dug. It will readily be perceived that *figs.* 4 and 6, are indeed other caſes of level cutting, occurring wherever the principal engineer has, in croſſing a vale, or point of a hill, found it neceſſary to preſerve his level above or below what would otherwiſe have been deſirable, if to be accompliſhed, as in our firſt caſe. The engineer will find abundant inſtances of *figs.* 1, 4, and 6, in all their degrees, and in a great portion of which there will either be a want of ſtuff to form the banks, as in *fig.* 4, or a redundancy from the deeper cutting, as in *fig.* 6, and the perfection of his ſkill will be ſhewn in ſo conducting the line, that every embankment, as *fig.* 4, ſhall have deep-cutting at both, or at leaſt at one of its ends, to furniſh the extra ſtuff, with the leaſt expence in moving it; in like manner, every deep-cutting, as *fig.* 6, ſhould have embankments at one or both of its ends, to receive the extra ſtuff. It is further evident, that the other three caſes, viz. *figs.* 2, 3, and 5, are but varieties of ſide-lying ground, or wherein the canal is conducted along the ſide or ſlope of a hill; and where it is evident, that a proper choice of the ſituation of the canal, higher up or lower down the hill, may occaſion A B C E and L I K P, the banking in *fig.* 2, together to be exactly equal to E F G L, the digging in this caſe; in like manner, where the ſlope of the hill is ſo conſiderable as to admit of no upper bank, as *fig.* 3, the bank A B C E may be equal to the cutting E F G I K P; it may be on a conſiderable ſlope that embanking is required, as in *fig.* 5, in order to preſerve the moſt direct line, or to reach any particular object; or deep-cutting may, and often does, occur in ſloping ground, and not in level, as we have ſhewn in *fig.* 6, but it ſeemed unneceſſary farther to multiply our caſes to delineate ſuch varieties. An attentive reader will find no difficulty in tracing every poſſible variation, by conſidering the line A′ P′, which repreſents the ground to vary in all degrees both of height and inclination, while the banks and canal, A B C F G I K P, remain fixed; and in this, almoſt the ſimpleſt inquiry that occurs in ſuch a work, it cannot fail of appearing, how eſſential a good knowledge of mathematics is to every engineer, and that none ought to be admitted to that honourable diſtinction, who are unlearned therein, however much they may have ſeen, or even executed, under the orders of abler men.

Our ſecond and third caſes requiring more than ordinary conſideration, before the line of the canal can be definitively ſettled, and the ground be marked out and purchaſed, unleſs waſte is committed, in purchaſing more than the company have occaſion for; we have repeated them again in *figs.* 7 and 8; and therein produced the lines of all the banks, by which the ſituation of the level-peg, of which we have ſpoken above, is ſhewn at a. It is alſo evident, that the lengths and poſitions of all the lines, B C, C F, F G, G I, and I K, being given, as alſo the poſitions of the lines B A, K P, and A′ P′; that the areas of the ſeveral triangles a B C, b F G, b C I, c I K, e F g, and e C K, and of the parallelogram I K g G, are known; and the calculation of theſe ſeveral triangles will generally, in practice, be very eaſy, from the conſideration of their being all ſimilar and iſoſceles. It is farther evident, that the triangles a E A, b E L, c P L, b E e, and f E P, are in general ſimilar: from ſuch conſiderations, theorems can be deduced, ſhewing, in every caſe, the diſtances d L and d E of the ſlope-holes, or edges of the cutting L and E, *fig.* 7, from the level-peg d, or of d E and d P in *fig.* 8; as likewiſe the diſtances d I and d C of the top edges of the canal, meaſured upon the level, from the level-peg; ſo that the ſtuff to be dug may juſt form the banks. The diſtances d A and d P, *fig.* 7, and d A, *fig.* 8, that determine the points A and P, at which the banks are to be begun, are alſo eaſily deducible from the ſame conſiderations; and it is evident, that A P is the width of ground that ought to be purchaſed, except in ſuch caſes where a hedge may be neceſſary at P, or, as may ſometimes be adviſable, a hedge at the bottom of the ſlope at A, inſtead of its top B, when the neceſſary width for one or both of theſe hedges muſt be added to A P. The inveſtigation of theorems for the above purpoſes, and others which we ſhall have occaſion to mention, would lead us farther into the ſubject than would, perhaps, be proper, eſpecially as no perſon ought, in our opinion, to undertake or meddle with the direction of ſuch works, who is not only capable of uſing a theorem laid down by another, but of inveſtigating and preparing rules for every caſe that can occur, or be wanting in his own practice. We proceed, therefore, to adviſe the reſident engineer, on being furniſhed with the dimenſions that the canal and its banks are to have, to calculate tables for readily finding the diſtance d h of the level-peg from the middle of the canal, meaſured on the ſlope of the hill, let the hill ſlope with whatever angle it may; or rather, let the angle i d h, or depreſſion of the ſlope below the horizontal line i d, be what it may; and this will be moſt conveniently expreſſed, not in degrees, but by the natural ſines of the angle of the depreſſion; becauſe then, if a meaſuring chain of 100 links be laid down at length, upon the ſlope of the ground, and the difference of the level of its two ends be taken in links by the ſpirit-level, theſe will expreſs the two firſt figures of the natural ſines of the depreſſion, which is quite as great exactneſs as ſuch tables need be calculated to. The engineer will now proceed to put in a ſtake oppoſite to each level-peg, at the proper calculated diſtance down the ſlope, for the approximate or ſuppoſed middle line of the canal: theſe ſtakes will ſeldom be found for any conſiderable diſtance together, to range in a ſtraight or in any other regular line, that will be proper for the canal: and a very difficult and nice part of the engineer's duty is now to be performed, in ſtaking out a new line with a taller or a quite different ſet of ſtakes from thoſe formerly uſed, to avoid confuſion; this is called ſtaking the middle range of the canal. The requiſites in this new line or range for the centre of the canal is, that it ſhould as nearly coincide in every part with the ſtakes that were laſt put in by the calculation, as poſſible; that, where, in order to preſerve a regular and handſome line, and avoid the aukward, inconvenient, and unmeaning crooks and bends, with which too many of our canals, and even ſome of the lateſt conſtruction, are almoſt in every part diſgraced, the line is conducted higher than the calculated ſtakes for one or more ſtakes together, care muſt be taken that it ſhall quickly be conducted below others, ſo that the redundancy in cutting deeper into the hill in one place may be as exactly as poſſible balanced by a deficiency juſt by, owing to the line being conducted below the level-ſtakes. Beſides the conſideration above, it will be the time now to eſtimate and conſider the quantity of ſtuff that will be wanted to land up every bridge and lock, and to give extra thickneſs to the banks on which any toll-houſes, warehouſes, or other buildings, are to be erected, or trade carried on.

In narrow canals, or branches of that deſcription, it will be neceſſary to provide for wider places at ſhort intervals, for barges to turn, and to lie in while others paſs them; conſiderable ſkill and care are requiſite in the choice of proper places for ſuch purpoſe: they ought to be ſo ſituate that barge-men can mutually ſee each other approaching on narrow canals or branches, and provide for paſſing, without either of them having to drag their barge back again to a paſſing-place, as too often happens; at the ſame time, they ought to be choſen, if poſſible, in ſuch hollow or low places as will admit of widening the canal without much extra expence. Another conſideration is, the excavation of baſons, docks, or wharfs, from which ſtuff may accumulate, which ought to be uſed up, if poſſible, in embanking the line juſt by. Many canal companies have ſeen it their intereſt, on proper and timely application from land-owners, who were deſirous of erecting wharfs, to direct their engineer to calculate upon, and to excavate the additional width neceſſary for ſuch purpoſe, at the company's expence; this and the extra or deeper cutting that there muſt always be, in the approach to a lock on the lower ſide, and of embanking on the ſame approach on the upper ſide, ſhould alſo be well conſidered and accurately calculated; and full and explicit memorandums ought to be entered in the engineer's field-book at the time, where the ſtuff was calculated to be had from for every embankment, and where the ſtuff is to be diſpoſed of from every deeper cutting or extraordinary excavation. Theſe memorandums will prove of the moſt important uſe in the reviſal of the whole length of line or diſtrict that is about to be fixed; as alſo, in contracting for and letting of the work afterwards, by being able, without fear of miſtake, to point out which way every part of the ſtuff is to be thrown or wheeled, as faſt as it is dug, and that no part of the ſame may want moving a ſecond time, or any wide or gouty places be made to disfigure the canal for finding ſtuff; or, what is often of more fatal conſequence, the canal being dug deeper than uſual for ſuch purpoſe.

After the line ſhall have been thus marked out with the utmoſt care, it will ſtill be prudent for the engineer to reviſe it again, and to make pretty accurate calculations of the quantity of ſtuff wanting, or to ſpare in particular places; in theſe kinds of calculations the engineer will find the moſt important aid in a ready uſe of the *ſlide-rule;* and we beg here to mention that a gentleman who has long diſtinguiſhed himſelf by the various and important uſes to which he has made the ſlide-rule ſubſervient, has prepared a ſhort but complete tract on its appplication in the concerns of an engineer, which it is hoped that he will ere long publiſh. Perhaps, on the review of the line, the curves or bends thereon may in ſome caſes be eaſed, and beauty and convenience may be more fully attained without much, or often any extra expence. The *Droitwich* canal has been mentioned as one on which theſe points have been the moſt fully attended to. The portion of the canal that has been thus ſtaked out and reviſed, may now have the boundary lines marked out of the land to be purchaſed; and the ſurveyor ſhould proceed without delay to ſurvey the ſame, and to treat with the owners for the purchaſe, as we have before mentioned. It will be among the firſt works to dig out for the foundations of the locks, if they are not already in hand, and for the bridges, if the ſeaſon of the year and ſupply of bricks and work-men will admit of their proceeding immediately: the ſeveral drains or culverts that are to paſs under the canal ſhould alſo be dug out, and prepared for the maſons or bricklayers, and the ſeveral ſafety-gates, ſtop-planks, weirs, and other erections, which we ſhall notice more particularly further on. It may be proper here to caution the engineer, that in caſe the pipes of any water-works, or that ſupply any gentleman's houſe, croſs the line of the canal, ſuch pipes ſhould be laid at once, two or three feet beneath the bottom of the intended canal, with an eaſy deſcent and aſcent therefrom, and the ground be made good again as ſoon as poſſible, both to prevent their being damaged in cutting the canal, and being expoſed to froſt, or to thieves, if of lead, by lying bare; and in caſe ſuch pipes are found old or decayed, new ones of lead or caſt iron ſhould by all means be laid in the deep part under the canal. The top-ſoil ſhould be carefully removed; and in order to determine readily and correctly the places of the ſlope-holes at E and L, *fig.* 7, and E and P, *fig.* 8, the engineer will find it uſeful to calculate the diſtances of d E and d L, and d P, by a general theorem, in terms of d h and h i, and to make tables for the ſeveral values of thoſe data, that are likely to occur. The values of d P and d A, *fig.* 7, would be alike uſeful in a table for determining the limits of the banks that are to be raiſed.

Before cutting out the lock-ſpit, or ſmall trench between the ſeveral ſlope-holes, as a guide to the men who are to dig, the engineer ought to cauſe holes to be dug in the line of the canal, near every ſecond or third level-peg, or oftener, if the ſoil be variable, in order to prove the ſoil to a greater depth by two or three feet than the cutting of the canal is to extend; and each of theſe the engineer ought carefully to inſpect, in order to determine what puddling or lining will be neceſſary; and what will be the difficulties of digging, owing to the hardneſs of the ſtuff, or to water that muſt be pumped out, &c.; all which circumſtances, as well as the extra diſtance that any part of the ſtuff may require to be moved, muſt be well conſidered before the work can be let to the contractors or hag-maſters.

The *puddling* or *lining* of a canal, to make it hold water, is a matter of the greateſt importance, and we ſhall conſider five caſes, in *figs.* 9, 10, 11, 12, and 13, that are likely to occur or preſent themſelves in the ſearch, into the ſoil that is to be dug, by ſinking holes as above mentioned: the firſt caſe we ſuppoſe to be that in which the whole is clay, loam, or other water-tight ſtuff, as ſhewn by the dark ſhading in *fig.* 9: all ſoils that will hold water, and not let it ſoak or percolate freely through them, are called water-tight. Our ſecond caſe, *fig.* 10, is that in which the whole cutting will be in ſand, gravel, looſe or open rock, or any other matters that will let water eaſily through them, and ſuch are called porous ſoils or ſtuff. The third caſe we ſuppoſe to have a thin ſtratum of water-tight ſtuff on the ſurface, ſhewn by the dark ſhading in *fig.* 11, and to have porous ſtuff for a conſiderable depth below, here diſtinguiſhed by dots. The fourth caſe may have porous ſtuff near the ſurface, and water-tight ſtuff at the bottom of the canal, as in *fig.* 12. The fifth caſe is that where water-tight ſtuff appears on the ſurface, as *fig.* 13, below this a ſtratum of porous ſtuff, but having again water-tight ſtuff at no great diſtance below the intended bottom of the canal. The new raiſed banks that are left unſhaded in all the five figures, are always to be conſidered as porous ſtuff, as indeed they will always prove at firſt, and in a great portion of ſoils they would ever remain ſo, unleſs either puddling or lining was applied; all ground that has been dug or diſturbed muſt alſo be conſidered as porous. It ſhould alſo be remarked that any kind of ſoil which is perforated much by worms or other inſects, ſhould in canal-digging be conſidered as porous ſtuff. *Puddle* is not, as ſome have attempted to deſcribe it, a kind of thin earth mortar, *ſpread* on places intended to be ſecured, and ſuffered to be *quite dry* before another coat of it is applied; but it is a maſs of earth reduced to a ſemifluid ſtate by working and chopping it about with a ſpade, while water juſt in the proper quantity is applied, until the maſs is rendered homogeneous, and ſo much condenſed, that water cannot afterwards paſs through it, or but very ſlowly. The beſt *puddling-ſtuff* is rather a lightiſh loam, with a mixture of coarſe ſand or fine gravel in it; very ſtrong clay is unfit for it, on account of the great quantity of water which it will hold, and its diſpoſition to ſhrink and crack as this eſcapes; vegetable mould or top-ſoil is very improper, on account of the roots and other matters liable to decay and leave cavities in it, but more on account of the temptation that theſe afford to worms and moles to work into it, in ſearch of their food: where puddling-ſtuff is not to be met with, containing a due mixture of ſharp ſand or rough ſmall gravel ſtones, it is not unuſual to procure ſuch to mix with the loam, to prevent moles and rats from working in it; but no ſtones larger than about the ſize of muſket bullets ought to be admitted. That the principal operation of puddling conſiſts in conſolidating the maſs is, we think, evident, from the great condenſation that takes place: it is not an uncommon caſe, where a ditch is dug, apparently in firm ſoil, that though great quantities of water are added during the operation, yet the ſoil that has been dug out will not more than two thirds fill up the ditch again, when properly worked as puddle. It ſhould ſeem alſo, that puddle is rendered by that operation capable of holding a certain proportion of water with great obſtinacy, and that it is more fit to hold than tranſmit water. It is ſo far from true, that puddle ought to be ſuffered to get quite dry, that it entirely ſpoils, when by expoſure to the air it is too much dried; and many canals which have remained unfilled with water during a ſummer, after their puddling or lining has been done, have thereby become very leaky, owing to the cracks in the puddle-ditches and linings. One of the firſt cares of an engineer, when beginning to cut a canal, is to diſcover whether good puddling-ſtuff is in plenty, and if it be not, it muſt be ſought for and carefully wheeled out or reſerved wherever any is found in the digging; or perhaps procured at conſiderable diſtances from the line, and brought to it in carts. It has happened in ſome ſtone-brach or looſe rocky ſoils, that all the puddling-ſtuff for ſeveral miles of the line, required to be brought to it; but even this expence, ſerious as it may be, ought not to induce the copying of thoſe, who have left miles of ſuch banks without any puddling, and have made a winter canal, but which no ſtream of water that is to be procured can keep full in the ſummer months. It is uſual in canal acts to inſert a clauſe for the ſecurity of the land-owners, to require the company to cauſe all the banks that need it to be ſecured by puddling, to prevent damage to the land below by leakage: and it would have been well for all parties in many inſtances, if this clauſe had been enforced. It appears that the Dutch have been in the habit of making mud-ditches to ſecure the banks of their canals and embankments, from time immemorial; and that operations ſimilar to our puddling have been long known on the continent, but it is not clear at what period it was introduced into this country; we think that the fens of Cambridgeſhire and Lincolnſhire, in which ſo many works have at different times been executed by Dutchmen, are the moſt likely places in which to ſearch for early evidence of its uſe. We cannot think that *James Brindley* was the firſt who ever uſed it in this country, although we might admit that the *Bridgewater*'s canal was the firſt in which it was ſyſtematically uſed as at the preſent day. If we compare our firſt, fourth, and fifth caſes, *figs.* 9, 12, and 13, we ſhall find in all of them a water-tight ſtratum as the baſis; and the practice in theſe caſes is to make a wall of puddle, called a puddle-ditch, or puddle-gutter, within the bank of the canal, as ſhewn in ſection, by *a c*, in the above figures; theſe puddle-gutters are uſually about three feet wide, and ſhould enter about a foot into the water-tight ſtuff, on which they are always to be begun: and they ſhould be carried up as the work proceeds to the height of the top-water line, or a few inches higher. Our ſecond and third caſes, *figs.* 10 and 11, evidently will not admit of the above mode, becauſe we have here no water-tight ſtratum on which to begin a puddle-gutter as a bottom: in theſe caſes, therefore, it is uſual to apply a lining of puddle to the ſides and bottom of the canal, as ſhewn by the croſs ſhading in *figs.* 10 and 11: the proceſs of puddling and lining will occur more properly further on, as we proceed in deſcribing the operations of digging and forming the canal.

In order to deſcribe more intelligibly the proceſs of ſetting out and digging a canal, in the two caſes where *puddling* or *lining* will be requiſite, we have repeated our firſt and ſecond caſe, but on a larger ſcale, in *figs.* 14 and 15; wherein *p* is intended to repreſent the hole that has been before ſuppoſed to be ſunk, in order to prove the ſoil; and, according as this terminates in water-tight or porous ſtuff at its bottom, that puddle-ditches, *q c ſ w* and *x c ſ t*, *fig.* 14, or a lining, *q r ſ t* H G F D, *fig.* 15, is to be applied; D H being the height to which the water is to ſtand in the canal. The engineer will in the firſt caſe determine the place of E and L on the ground, and dig ſmall holes or nicks to mark the ſame, called ſlope-holes; but in the ſecond caſe other marks muſt be made at *n* and *v* about five feet from the former, to direct the beginning of the cuttings, with allowance for the lining. A ſkilful and very handy workman is now required to mark out the line upon the ground, called the lock-ſpit, between the ſlope-holes at E, *fig.* 14, above-mentioned, which we have ſuppoſed to be made at about two or three chains from each other. This is done by laying down and ſtretching a ſtrong line upon the ground, between two or more adjoining ſlope-holes, and if the canal is not to be ſtraight in that part, with ſmall pegs to give it the gradual and regular bend in every part that the canal is to have; the workman then proceeds, holding his ſpade or grafting tool not upright, but always with the ſlope C E, that the bank of the canal is to have, and ſtrikes it ſucceſſively into the ground cloſe to his line, until the whole length of the line is marked out; by this means, if the ground has ſudden undulations, or hollows, as continually happens, owing to the ridges and furrows of cultivated lands, and other cauſes, yet a regular line coinciding in every part with E is marked out upon the ſurface; before the line is taken up, another labourer follows on the other ſide of it, and ſtrikes in his tool inclining the contrary way, by which a triangular ſod or piece of earth is cut and thrown out: a ſimilar lock-ſpit muſt be cut on the other ſide of the canal at L; and the ſame at *n* and *v* in *fig.* 15. If neatneſs and regularity are properly conſulted, lock-ſpits for the extremities of the banks at A and P will alſo be proper, eſpecially if the land A A′ and P P′ is valuable, and the damage by the ſcattering and laying of the ſtuff would be conſiderable. The engineer has now to determine, in *fig.* 14, the points *c* and *d* for the beginning of the puddle-ditches, and theſe he ought to chuſe ſuch, that if the ſame were carried upright to the top-bank, *b* C or I *a* would be about one foot: if this is not ſtrictly attended to, the labourers or navigators, as they are called, will for their own convenience begin their puddle-ditch much too near the canal at E and L in ſome caſes, and not make it upright but hatching back to arrive at *a b*; and puddle-ditches ſo made are apt, owing to the ſettling of the bank, to get broken and be ſpoiled. It may be proper here to remark, that canals ſet out with the ſcientific precautions and care that we have recommended, will always have the proper quantity of ſtuff to allow for the ſettlement of the banks, becauſe A B C E + L I K P = E F G L, in the ſame ſettled or conſolidated ſtate, that the latter part was before the digging commenced: it will, however, be proper to give the contractors a table or rule ſhewing, according to the height, as *a c*, what extra height a ſuddenly raiſed bank is required to be, to allow for ſettling: and it is evident that the ſlopes of ſuch banks muſt be ſteeper in the firſt inſtance, than they are intended ultimately to be.

We may now ſuppoſe the engineer to proceed to the letting of the cutting of certain lengths of the canal to contractors or hag-maſters, who will employ a number of navigators under them, in digging and puddling the canal. It is uſual to let the work at a certain price per cubic yard of digging, and to pay for the puddling and lining either at a certain price per cubic yard, or per yard run of the canal. The engineer ought to inform himſelf thoroughly on the difficulties and facilities which attend the work he is about to let, and to draw up a ſhort but explicit contract to be ſigned by the contractor. We cannot but recommend that all contracts for material or large jobs of work, not only in cutting, but for the maſon's, and other works in particular, ſhould be ſubmitted to the principal engineer for his approbation, before they are ſigned or finally concluded on. The prices allowed ought to be fair and liberal, according to the circumſtances, ſo that the contractor may have no pretence on account of low prices, to ſlight his work, particularly the puddling; and they ought in every inſtance to be ſtrictly looked after, and made to undo and renew immediately, any work that ſhall be found improperly performed. We recommend it to the engineer to keep a ſtrict account, by means of his overſeers or counters, of all the men's time that are employed upon the works; diſtinguiſhing particularly the number upon each work, and whether employed by the day, under the company, or upon the work that is let to contractors. Theſe particulars are moſt eſſential towards knowing, what money ought to be advanced to the contractor during the progreſs of his job, and towards informing and maturing the judgment of the engineer, in the length of time that a certain number of men will be in performing any future work that he may have to direct; and a calculation ought to be made in every inſtance of the day-work, and compared with the contract price, by which alone a correct judgment can be formed of the proper prices at which work ought afterwards to be let, ſo that the labourers may receive proper wages, proportionate to their exertions, and the contractor be amply paid for his time, ſkill, and ſuperintendance; and yet economy and the intereſt of the company be duly conſulted. Barrows and wheeling-planks, horſing-blocks, and other implements, are generally found by the company; and it is uſual to conſider 20 to 25 yards, to be a ſtage of wheeling, and a price per cubic yard to be fixed, according to the number of ſtages that ſoil is to be moved: where this diſtance exceeds 100 yards, it will not often be eligible to perform it by wheel-barrows; and runs of planks with an eaſy deſcent, if the ſame is practicable, ſhould be then laid for large two-wheeled barrows, or trucks to be uſed thereon.

The cutting of a canal being let, the work is uſually commenced by a labourer, on the part E *g*, *fig.* 14 or 15, on the lower ſide of the canal; and from the lock-ſpit at E he marks out a certain width to *g*, ſuch that he can throw or caſt the ſtuff as he digs it, on to the part A *c*, and ſo that the heap may not obſtruct the intended puddle-gutter *c d*. The ſide E F he is careful to cut down in the proper ſlope of the bank; the other ſide is uſually cut ſtraight down, and this work is continued until he comes to the bottom of the intended canal at F *h*, and this ſpace E F *h g* is called the "reaching." The ſame proceſs is followed on the lower ſide of parts that want lining, as *fig.* 15, except that *n r h g* is the reaching in this caſe, and that there is no neceſſity to throw the ſtuff further in this caſe, than that it may lie upon *n* A without rolling back into the work; and it is uſual, if the reaching will not be very deep, to lay two or three rows of ſods or ſound ſpits of earth, with regularity in the face of the ſlope *n q* to form part of the bank, and to throw the other ſtuff over theſe. Reachings are alſo to be dug on the upper ſide of the canal, as *i k* G L, or at leaſt as much ſtuff is to be thrown out therefrom as can conveniently be ſtowed upon *d* P and *v* P, *figs.* 14 and 15.

It is now time to commence the puddling in *fig.* 14, and a labourer begins by digging out the bottom of the intended puddle-ditch *c e f d*; if the ſoil dug out is good puddling-ſtuff, he lays it on the part *d* E, if otherwiſe he throws it at once on to the heap on A *c*. A careful examination of the face E F of the reaching will ſhew to what depth the puddle-ditch *d f* ought to be carried in every part, to reach and interſect any faulty places, or veins of lighter ſoil, or worm, rat, or mole-holes that may accidentally occur in the bank. After the puddle-ditch is dug clean out to its proper depth, and this is a circumſtance that the engineer or ſome careful overſeer ought always to look particularly to, about 9 or 10 inches thereof is to be filled looſely up with puddling-ſtuff, either from that which comes out, or from the neareſt heap in reſerve, all large ſtones, ſticks, ſtraws, or other extraneous matters being carefully picked out as the ſtuff is ſprinkled in: by this time, unleſs the ſeaſon is very dry, it is probable that ſome water will be collected in the bottom of the reaching F *h*, and this ſhould be laded out with a ſcoop into the puddle-ditch, ſo as to give the ſtuff therein a good wetting; if the puddling-ſtuff be of the ſtiffer kind, or was very dry, it will be right for the labourer to betake himſelf to ſome other part of the work for two or three hours, but perhaps giving his ſtuff another ſprinkling of water in the interim; he may then proceed with the puddling; and for this purpoſe he ought to be provided with a ſtout pair of puddling-boots, that will keep out water; he begins at one end of the trench, and keeps chopping with his tool into the ſtuff and quite through it, giving his tool a lunging motion every time before it is withdrawn, ſo as to let the water into and to ſtir every part of the puddling-ſtuff; if more water is wanted, another labourer is ſet to lade it out of the reaching as before; and the puddler thus proceeds, chopping down at every inch or thereabouts as he ſlowly advances, and trampling about at the ſame time as much as he can with his feet, which greatly aſſiſts the operation: when arrived at the end of the trench, he returns and repeats the ſame operation, until every part of the puddle is properly worked; which is known by the tool going equally eaſy into it in every part, which it would not do if any dry lumps remained, and the whole being in a ſemifluid ſtate; giving the puddling-ſtuff juſt the due quantity of water is very eſſential to its working well, and this, experience will ſoon point out.

Very great care and management will, in general, be required on the part of the engineer, to furniſh water for the puddling: it will often require to be brought in temporary trenches, perhaps acroſs ſeveral fields from ſome mill-dam, large pond, or ſpring of water above the canal; for which purpoſe general powers ought to be given in the act, upon condition of levelling and making all ſuch trenches good again as ſoon as poſſible, and paying for the damage; often times puddling water is not to be had without pumping it up, and conveying it conſiderable diſtances in troughs, of which great numbers will be required. It will very often be requiſite to convey the water acroſs the canal in troughs to the different puddle gutters, and plenty of treſtles ſhould be in readineſs for ſupporting theſe troughs at the requiſite heights. Conſiderable care will be neceſſary to turn off the ſurplus water, into ſome channel where it can run off without flooding the works; or to ſtop it at its ſource; this laſt ought always to be adopted, when the ſupply is not very plentiful, or the owner of the ſtream or pond might be injured by taking a conſtant ſtream from him, during the progreſs of the work. The firſt or bottom courſe of puddle being properly worked as above, it ſhould then be ſuffered to ſtand two or three days undiſturbed, and without any more water being given to it; when it will be found ſufficiently ſet that a man may ſtep on to it without ſinking in; it is then ready to receive a ſecond courſe; the firſt ſtep is to ſcrape off and remove any lumps of earth, ſtones, ſticks, or other matter which may have fallen into the puddle-ditch; about 10 inches thick of puddling ſtuff is then to be ſprinkled lightly into the ditch as before; and water is to be applied either from the reaching, or from ſome of the troughs which we have been mentioning: ſome hours time is to be allowed for the ſtuff to ſoak, unleſs it be light loam, and moiſt at the time of putting it into the ditch; in ſuch caſe, the puddling may be begun almoſt immediately: care muſt be taken that the tool be made to penetrate a ſmall diſtance into the old puddle at every chop, in order that the two courſes or layers may be properly incorporated. After this couſe is properly wetted and worked, it muſt ſtand the proper time to ſet as before, but by no means to get dry, otherwiſe it will be found full of cracks and muſt be worked anew: and in caſe, owing to any temporary ſuſpenſion of the work, it ſhould be neceſſary to leave a puddle-ditch before it is finiſhed, it ought always to be covered, and left with a dry or unworked courſe of puddling-ſtuff upon it, to keep the air from it, and preſerve the proper moiſture in it.

When a ſufficient number of courſes of puddle have been added, to fill up the ditch *c e f d*, two or three rows or courſes of ſods, or ſpits of earth, muſt be laid on each ſide, to raiſe the ditch ſo much higher; at the ſame time that the heap of ſtuff on A *c* is levelled down, and other ſtuff is brought by the men, who are wheeling from the bulk *g h k i* that is left in the middle of the canal, and laid on *d* E to back up the ſpits or ſods: after cleaning the ſurface of the puddle, if properly ſet, it will be ready to receive another courſe of puddling-ſtuff, the water muſt be turned on, it muſt have time to ſoak, if neceſſary, and then be worked and ſtand to ſet as before: other rows of ſpits of earth may then be laid, to raiſe the ſides of the puddle-ditch, and the bank may be made up to the ſame height by freſh ſtuff wheeled in from the canal; and care being taken to lay ſpits of earth to form the ſlopes A B, and E C, as the works proceed upwards, particularly the inſide ſlope C E, which ſhould be well trod and conſolidated by ſtrokes of the tool to prevent its falling down, or being diſturbed by the water when the canal is filled; another courſe of puddling-ſtuff is then to be added, and all the ſame proceſs gone through till the puddle has arrived at *q w*, the height of top-water, or an inch or two higher, which being properly ſet, the bank is to be made up, covering the puddle completely up with common ſtuff, to the intended height of the top-bank B C, with proper allowance for the ſettling; and obſerving that the puddle will not ſettle near ſo much as the other ſtuff, if at all. The proceſs is no way different, by which the other bank L I K P, and its puddle-ditch, are to be carried up, and completed to the intended height. The part of the canal, with puddle-gutters, *fig.* 14, of which we have been ſpeaking, has, in general, a lump or ridge of ſtuff remaining in the middle of its bottom, until the very laſt: a different ſyſtem ought, however, to be purſued with ſuch parts, *fig.* 15, as require to be lined; here the banks AB *q n*, and *v t* KP may be at once made up, and the whole of the ſpace *n r s v* ought to be cleared for certain diſtances, before the lining of the bottom can be begun. A great deal of management is required by the overſeer or contractor, to manage all theſe parts of their buſineſs, ſo that there is no hindrance of any part of the work, that every man is provided with ſtuff by the wheelers, when he wants it to make up his banks or to puddle, and that the parts to be lined are cleared in time. To accompliſh all theſe objects, a good part of the ſtuff cannot be wheeled directly out to the neareſt or oppoſite points of the bank, but it muſt be worked forwards and backwards obliquely, on the runs of wheeling planks by the wheelers, as occaſion may require. It may often be neceſſary to exceed one or two, or perhaps more, ſtages of wheeling, to avoid taking out the ſtuff and clamping it, by which it would require filling again, damage would, in moſt caſes, be incurred on the adjoining lands, and frequently the puddling and working of the banks would be impeded, by croſſing them to land the ſtuff.

A length of the canal that is to be *lined* being cleared, and the bottom levelled and cleaned ſmooth down to the line *r s*, a courſe of puddling-ſtuff about 10 or 12 inches in thickneſs is to be ſpread over it, with all the precautions, to extract extraneous and hurtful matters, which have been before given, and the whole is to be wetted and allowed to ſoak if neceſſary, as before: the working of this puddle is now to be begun; and as the extent will generally be large, ſeveral men may be employed, at once, upon it, ſo as to make it worth while for an overſeer employed by the company, to attend them conſtantly to ſee that no part of the work is ſlighted: as the bottom in this caſe is ſuppoſed to be ſand, looſe ruble of a rock, chalk, or other matters, that would injure the puddle if mixed therewith, we have recommended a thicker courſe at firſt than is uſual of puddling-ſtuff, and in working the ſame the men ought not to ſtrike their tools deeper or even quite ſo deep as the bottom of the puddling-ſtuff to avoid diſturbing the bottom. When this courſe of puddle has been allowed to ſet, another courſe of about nine inches is to be added, and treated as before, till about three feet of puddle is added, if the ſoil is very porous; and the top courſe being ſet, a courſe 18 inches or two feet thick of the common ſoil or ſtuff ſhould be laid evenly upon it and the bottom levelled; this covering of the bottom ſhould be rather dry, and not in large lumps, or with great ſtones or ſticks in it.

The *lining of the ſides* is now to be proceeded with as follows; the top covering of the bottom ſhould be removed for three feet in width next each of the ſloping banks; and the ſurface of the puddle be carefully cleared of dry lumps, ſtones, &c.; a thickneſs of nine inches of good puddling-ſtuff is now to be laid in this place and wetted and worked, and allowed to ſet as before directed, when another nine inches is to be added in like manner; ſome common ſtuff from the digging of the canal is then to be brought in ſpits or ſods, and carefully piled up for two feet in width, and about nine inches in height, hatching-back before and behind, agreeable to the ſlopes F E and G L, and leaving a ſpace or puddle-ditch behind, next to the ſides *r n*, and *s v*; the ſurface of the puddle at the bottom of theſe is to be carefully cleared, nine inches of puddling-ſtuff applied, wetted, worked, and allowed to ſet as before: more ſpits or ſods are then to be piled in the front, as a facing to keep up the puddle, and their interſtices ſhould be filled with fine ſtuff to make the whole ſolid; when puddling-ſtuff is again to be applied behind, and the ſame proceſs repeated till the puddle and facing arrive at *q* D and H *t*, when the remainder is to be made up with dry ſtuff and ſpits to the top-bank level at C and I, as directed in the former caſe.

The laſt of theſe ways of making a canal water-tight is the more tedious and expenſive of the two; it is however general, and may be applied in any ſituation with perfect ſucceſs. Mr. *Thomas Telford*, in *Plymley's Agricultural Report of Shropſhire*, 8vo. p. 296, when ſpeaking of the *Shropſhire* canal, ſays, "This canal, carried over high and rugged ground, along banks of ſlipping loam, over old coal-mines, and over where coal-mines and iron-ſtone are now actually worked under it, is a ſatisfactory proof that there is ſcarcely any ground ſo difficult but where, with proper exertions and care, a convenient water conveyance may always be obtained." And we have heard of inſtances of canals being conducted over ground ſo rocky, and abounding with ſuch great chaſms, and looſe pieces of rock, that many yards together of the canal bottom might have fallen in, had not the precaution been firſt taken, of removing all the ſmaller and looſe ſtones and rubbiſh, and wedging in the large looſe pieces of rock with ſtones, ſet in mortar, and thus rendering the foundation ſound, on which ſoil to fill up the inequalities, and a lining and facing was applied as above, with perfect ſucceſs. We have already obſerved, that ſome perſons have thought it right to omit puddling or lining, where ſprings appeared in the bank of a canal; and the matter is of ſo much conſequence, that we beg farther to obſerve, that the appearance or non-appearance of ſprings ought in general to have no effect in determining the propriety of theſe eſſential meaſures; if a ſpring is of any uſe to a canal it will riſe, owing to the puddle-ditch or lining, and run over the ſame into the canal, and no water will be thereby loſt; and if it will not ſo riſe, it may ſafely be ranked as a drain of the moſt miſchievous kind, inſtead of a ſupply, and therefore very eſſential to be ſtopped up.

In caſe it is found that there is ſtuff to ſpare after completing the banks, it will ſometimes be adviſable to remove the top-ſoil from A′ A in low places, and after ſpreading the extra ſtuff ſo as to make the ground good, to return and ſpread the ſoil upon it: the part P P′ will often admit of ſimilar treatment, and ſometimes ſudden hollows there may be filled up, ſo as to have a fall to the top-bank I K, and avoid a deep ditch through an adjoining ſwell or riſe of the ground at P, to carry off the rain water to a culvert where it is to paſs under the canal: where it happens that P P′ is waſte or ground of little value, or the company is poſſeſſed of a piece that they have been obliged to purchaſe and cannot readily diſpoſe of, it may be proper to make a heap or ſpoil-bank of any extra-ſtuff, to be afterwards boated away as occaſion may require. If a deficiency of ſtuff is experienced to complete the banks, the part P P′ furniſhes a good reſource in many inſtances; the top ſoil being removed on the higher parts, an excavation like P *y* P′, *fig.* 14 and 15, may, and indeed muſt in many inſtances, be made with a proper fall for conveying the rain-water that falls in every part above the canal to the brook or culvert that is to take it off; the ſlope P′ *y* ought to be ſo eaſy, and the top-ſoil ſo ſpread, that the land ſhall be as fit for agricultural purpoſes afterwards as before. Another reſource ought in an earlier ſtage of the buſineſs to be provided, in the deep-cutting, by marking out a yard or two or more width of ground to be purchaſed on the upper or deeper ſide, than is actually wanted, by which a great deal of ſtuff may be procured at a comparatively ſmall expence of land: it muſt be evident, that the reſources we have pointed out above are inadequate to receive any great redundancy, or to ſupply any great deficiencies of ſtuff, and are only ſufficient where the canal has been ſet out with ſcrupulous care; bungling, or careleſs canal-makers muſt be content to leave laſting marks of their incapacity or folly behind them, in the many ſudden bends into the hill that they are obliged to make to obtain ſtuff, and out of it to diſpoſe of the ſame in other places, with numerous wider or deeper places on the canal to make up the banks, or in enormous ſpoil-banks or uſeleſs excavations. Where a reſerve of ſtuff has been made in the deep-cuttings at ſeveral points on each level or reach of a canal, as above-mentioned, it will be the better fault of the two, to experience a deficiency of ſtuff; becauſe as ſoon as the bottom of the canal has been cleared, and the lining of the bottom and ſides for ſome height performed, or the puddle-ditches carried up, the canal may have 18 inches or 2 feet of water let into it, and dirt-boats may be uſed to carry ſtuff from the deep cuttings to make up the banks in other places; whereas all redundant or ſpare ſtuff muſt be got out before the bottom lining can be applied, or any effectual uſe made of boats to move ſtuff from place to place; and the ſame advantages will be experienced in ſituations where puddling-ſtuff is only to be procured at particular points on the line, by clearing out and completing the bottom part of the canal for conſiderable lengths, ſo that dirt-boats may be uſed to bring the ſame for the puddling or lining of the upper part of the banks, which, if there is ſpare ſtuff, cannot be effected without heavy expences in moving the ſame and forming ſpoil-banks. Where the line of a canal is to croſs an extenſive ſtratum of valuable brick earth, or one of good gravel for making of roads, it will often be adviſable, eſpecially if the line can be rendered more direct thereby, when ſetting out the canal, to cut pretty deep into ſuch materials, and even quite through the gravel, if the ſame is practicable, as might have been done at Dawley-deep, between Paddington and Uxbridge, on the *Grand-Junction* canal; for although conſiderable expence will in the firſt inſtance be incurred in digging and in damage for ſpoil-banks, yet ſuch materials, as good brick-earth and gravel, will in almoſt every inſtance find a market as ſoon as the canal is opened; ſuch a ſituation of the canal may prove of eſſential ſervice to its trade, by enabling the adjoining proprietors to work the whole thickneſs of their brick-earth, gravel, or other uſeful matters, and deſtroy but very little of the ſurface of the ground, and without being annoyed by water, but which the canal would catch in very conſiderable quantities perhaps, inſtead of loſing water by preſerving a high level through porous ſtuff. It is highly to the intereſt of a canal-company to give facility to the getting and conveyance of all uſeful articles within their diſtrict, at the cheapeſt poſſible rates, as the only means of opening new ſources of trade or manufactures, by which their concern will be in the moſt eſſential degree benefitted. In diſtricts where ſtone and gravel for making and repairing of roads are ſcarce, it will be proper to pay the labourers certain rates per cubic yard for all the ſtones or gravel that they may collect out during the work, and ſtack in proper places; as reſources for the making of the towing-path C *l*, *fig.* 15, and for making good the landing or aſcent to the ſeveral bridges, and the ſeveral pieces of new road that the engineer will have to form, near to the canal and bridges; the lock-banks and all wharfs and landing places ſhould alſo be covered with good gravel to render them ſafe and convenient for uſe: if good gravel can in places be interſected in deep-cuttings, much of the above expence, as well as of cartage, may be ſaved, by an early uſe of dirt-boats in the bottom of the canal. It cannot, we think, have failed to ſtrike every reader ere this, how very important and various the duties of the reſident engineer are; but the ſame will be much more apparent, when we ſhall have finiſhed, in the following pages, the more particular obſervations that occur to us under the heads of reſervoirs, feeders, aqueducts, embankments, culverts, ſafety-gates, weirs, tunnels, deep-cuttings, locks, ſubſtitutes for locks, inclined planes, rail-ways, bridges, towing-paths, fences, drains, boats, towing or moving boats and trams, cranes and implements, &c. of which we ſhall proceed to treat; after obſerving, that none but men of the ſtricteſt integrity and extenſive knowledge ought to be employed as reſident engineers, and that the committee and principal engineer ought not to heſitate in offering and paying ſuch men a very liberal ſalary, to engage the whole of their time; and, that too great a length of line or extent of buſineſs ſhould not be put upon ſuch a man. This is the proper ſphere, where young men or others, of knowledge and perſevering induſtry, who are coming forwards in their profeſſion, ſhould exerciſe and give ſpecimens of their abilities as engineers; and it will prove of the utmoſt importance to ſuch, as well as to a company who have an extenſive line of canal to conſtruct, to employ more than one of ſuch men at the ſame time, upon adjoining lengths of the canal; where their emulation may be excited in an honourable conteſt, as to thoſe who ſhall execute their portion of buſineſs in the moſt complete, orderly, and economical manner.

One of the firſt conſiderations relating to the *conſtruction* of *a Reſervoir* for ſupplying a canal, is the ſupply of water that is to be expected for it, and in what proportions at different times of the year: for this purpoſe we ſuppoſe the engineer to be furniſhed with an accurate ſurvey of the vale or vales that lie above the intended reſervoir, ſo as to be able to calculate exactly, how many ſquare miles and fractions of ſurface drain towards or vent their rain-water through the part intended to be embanked for the reſervoir; it will be very proper alſo to be furniſhed, if poſſible, with the exact gauge or quantity of water that has actually in former years been diſcharged by the brook or ſtream that is to be embanked; as alſo with the quantity or depth of rain which uſually falls within the drainage of the intended reſervoir. If the length of time that has elapſed, ſince the ſituation of the reſervoir has been determined on, has not allowed of careful and accurate experiments being made on theſe points, the engineer muſt aſſume them from the beſt data that the information of millers and other perſons will afford, and the printed tables, or journals of rain, kept by curious perſons in the neareſt ſimilar ſituations, muſt be conſulted: it is particularly neceſſary to attend to this laſt circumſtance, becauſe there are, we believe, inſtances of places where the annual depth of rain does not amount to a foot, and others in which it exceeds five feet; while 23 inches is about the medium depth of rain annually, at or near London. The moſt perfect method of obtaining true information on this ſubject, is to gauge the different ſprings or ſtreams, from whence the ſupplies of water are to be derived, and thus to aſcertain the exact ſurplus, after the mills are amply furniſhed. In the great conteſt about the Rochdale canal, Mr. Rennie had all the ſtreams, which could be affected by the propoſed reſervoirs, gauged for about a year. He firſt aſcertained the ſtate of theſe ſtreams at a time when the mills were amply ſupplied with water, and had proper gauges fixed upon them. The daily difference was meaſured, and the ſurplus thus aſcertained amounted in the year 1793 to ſixteen times the ordinary produce of the rivers. The evaporation that takes place, from a given ſurface of water in different places, has not yet been ſo accurately obſerved as the importance of the ſubject to canal engineers deſerves: *Mr. Bevan's* obſervations thereon, at Leighton-Buzard in Bedfordſhire, continued for five years, to the end of 1804, gave an evaporation of 22.92 inches at a medium per annum, while the depth of rain there, in the ſame period, was obſerved to average 23.28 inches; in ſome years the evaporation conſiderably exceeded the depth of rain, and in others it fell as much ſhort of it or more. On this ſubject, ſee the article EVAPORATION.

It will ſometimes happen, that the valley in which the reſervoir is to be made, has other valleys parallel to it, on one or both of its ſides, ſuch, that by beginning a ſough or ſmall tunnel above the level of the reſervoir, continuing it with a ſmall riſe through the adjoining hill, and from its further end continuing a ditch or feeder along the ſide of the hill riſing gently as it proceeds till it interſects the bottom of the vale, a brook or conſiderable ſtream of water may at times be there interſected and brought into the reſervoir; or, another caſe may happen, in which the adjoining valleys inſtead of being parallel to, proceed directly from the reſervoir valley, and yet feeders may be ſet out, ſo as to collect great quantities of rain and ſpring water, from the ſides of the hills that ſlope towards the adjoining valleys, and through which it would otherwiſe eſcape. Both theſe methods we ſaw ſucceſsfully practiſed about the year 1796, for increaſing the ſupply to the new water-meadows which the late *Duke of Bedford* had directed his agent to conſtruct near Woburn. A parallel valley, which croſſes the turnpike road at about $43\frac{1}{8}$ miles from London, has its ſtream of water diverted at that point, and through a ſhort tunnel into the Woburn vale, which it otherwiſe would not have reached for a mile or more, and at a much lower level. From the loweſt point in the ridge of high land that ſeparates the Woburn vale from one that proceeds through Potſgrave pariſh towards Leighton, a trench or feeder was begun, and carried for a mile or more along the ſide of the hill in Potſgrave, by which the rain water of 3 or 400 acres of land was brought into a reſervoir in a branch of the Woburn vale, to be reſerved for uſe.

The engineer, who has well conſidered and aſcertained all the circumſtances of the vales in or near to which his reſervoir is to be conſtructed, will be able, by help of a number of levels, carried round to where the ſurface of the water will extend at every 5, 10, 15, 20, &c. feet in depth, or oftener, if the nature of the ground requires it, to calculate to what height the head of the intended reſervoir muſt be embanked to retain all the water that his vallies can ſupply, between the times that it is fed by rains and ſprings, and required to be let off to the canal or mills, or ſuch quantity only as it may be neceſſary ſo to retain, according to the principles before laid down.

The neceſſary height of the head or embankment for a reſervoir being determined, the next ſtep will be to examine minutely the nature of the ſtrata and ſoil that are to be covered with water, and whether the whole or any part of the ſame is ſo porous as to require lining with puddle, as alſo the nature of the ſtuff which is to be uſed in forming the head or bank, as thereon will depend, in a great meaſure, the degree of ſlope which the banks ought to have; $1\frac{1}{2}$ to 2 feet baſe to one in height ſeems the uſual ſlope; but if the ſoil ſhould prove a ſlippery clay, as at the Aldenham reſervoir, belonging to the *Grand Junction* canal, a greater ſlope ſhould be given, as well as the precaution taken, of putting in frequent layers of ſand or coarſe gravel, to leſſen the tendency of ſuch ſoil to ſlip. If the reſervoir will require bottom lining, yet ſtill it will not ſometimes be right to truſt to lining for the head of the reſervoir, but to carry up a puddle-ditch in the centre of the head, becauſe if the inſide of the head ſhould happen to ſlip, the lining would be broken and diſturbed. The ſlopes being ſettled, it will be right to make a croſs ſection of the valley at the place of the centre of the head, as A C B (*Plate I. Canals, fig.* 16.) and to determine by levelling, and mark out the places of, as many perpendiculars or equidiſtant ordinates a, b, c, &c. as the width of the head and the nature of the ſides of the hills A C and

C B may require; we are next to conſider, that the ſection of the intended bank at every one of the points a, b, c, &c. will be nearly triangular, as D G F, *fig.* 17. (except wanting a ſmall triangle G H I at top) K E being equal to the ordinate *a*, *b*, *c*, &c. in every caſe; the baſe D F, or width of the head at the different places, varying according to the height K E, and according to the inclination or fall of the ground D F, compared with the horizontal lines F L and I H. A theorem for E D and E F will readily be obtained with the above data, and theſe diſtances being calculated and laid off on the ground, ſo many points for the bottom of the ſlopes will be determined, and a careful workman will find no difficulty, by pegging down his line and holding his grafting-tool in the inclining poſition H D and I F, (as before mentioned reſpecting marking out the canal) to mark out a lock-ſpit, as a boundary or baſe for the intended embankment.

If the ſeveral triangular ſections D G F are taken near enough to each other, A *a*, *a b*, *b c*, &c. and are carefully calculated (for which purpoſe in very large works, tables framed from the theorem will be found the readieſt way), by deducting a triangular priſm, whoſe baſe is H G I, and length A B, *figs.* 16 and 17, the ſolid contents of the required bank will be very exactly obtained; and the moſt eligible ſpots for obtaining that quantity of ſtuff, as near as may be, without endangering the ſlipping or ſtability of the bank, may be marked out; and the work will then be in a ſtate to be let to the contractors who are to execute it. But before this is begun, it will be neceſſary to provide for the eſcape of the ſurplus water when the reſervoir ſhall be full, as alſo for letting out the water for uſe; for theſe purpoſes an arch of brick-work, or of ſtone, may be begun at the lower limit of the bank in the loweſt ground or brook courſe, as at D, in *fig.* 18, and continuing the ſame on a level to a point M, ſome diſtance within the head D H I E of the reſervoir; D′ L′ being the loweſt ground or longitudinal ſection of the valley. This arch ſhould be high enough for a plank to be ſupported and fixed on irons or bearers acroſs it, about a foot from its bottom, on which a man can conveniently walk along; and, for this purpoſe, the arch had better be made elliptical, or higher than it is wide; a ſecure iron gate ſhould alſo be provided, to be kept locked at a few yards into the arch from D, for excluding improper perſons. At the termination of the level arch at M, there ſhould be a circular well of 6 or 8 feet diameter more or leſs, according to the greatneſs of the floods that may be expected, to be ſunk 6 or 7 feet deeper than the arch D M; its bottom ſhould be formed either of one very large flat ſtone, or of a few well jointed ones laid on a courſe of puddle, and on this the ſteining of the well ſhould be begun, with bricks of the very beſt quality, well keyed up and embedded in cement; and having a courſe of puddle of 9 inches or a foot thick, worked all round behind them, allowing the ſame to ſet as the work advances in height; this well, and the arch D M, are to be ſecurely groined into each other at M; near to this groin, or within reach of a man ſtanding on the end of the plank above mentioned, which ſhould not advance quite up to the well, ſhould be a large braſs cock worked into the walling; the mouth of this cock ſhould be turned down, ſo as to diſcharge its ſtream of water exactly in the direction for the centre of the bottom of the well; and from the cock ſhould proceed a large pipe of lead or caſt iron behind the wall of the well at ſome diſtance, for which purpoſe it will require a conſiderable bend, and this pipe ſhould proceed, ſoundly embedded in good puddle, towards a convenient place as S, in the bottom of the reſervoir, where it ſhould terminate under a large and ſtout box full of holes, or a fine grating, to prevent the entrance of fiſh or any thing that might choak the pipe or cock. In conſtructing the arch before mentioned, after it has proceeded from D as far as the intended puddle-ditch *c d*; the puddle-ditch ſhould be dug out for ſome diſtance on each ſide acroſs the arch; the ſame ſhould be continued down to water-tight ſtuff, or at leaſt for ſome depth into other matter, if unfortunately ſuch is not within reach; and, when the puddle is carried up and ſet, as alſo a courſe of puddle in the bottom of the arch courſe *d* M, which ſhould have been dug deeper for ſuch purpoſe; the bottom of the remainder *d* M of the arch ſhould be carefully laid on the puddle, and a centering for the arch is to be laid on the ſame and firmly ſecured down; this precaution being neceſſary to prevent the ſemifluid puddle that is to be applied ſucceſſively withoutſide the arch, as it is carried up, from floating or burying up the centering along with the lower part of the arch. The work is thus to proceed until the part of the arch *d* M is completed, and incloſed completely in a caſe of good puddle, thoroughly and completely joined at one end into the puddle-ditch *a e f b*, and into the puddle that ſurrounds the well N M at the other. When the well-ſteining has been carried up to M, it will be neceſſary to increaſe the thickneſs of the puddle-wall round it, to three feet or more, taking care that the extra width is firmly bedded upon undiſturbed and ſolid earth. The well is intended to be carried up in the ſame manner, ſurrounded by puddle, and by a conical embankment of earth O P Q R, to within two feet of the height of the bank H I, leaving a channel of ſeveral yards wide, and of conſiderable depth, I O P, between it and the bank or head D H I E. It will be neceſſary for the engineer to calculate and mark out the baſe of this conical embankment upon the ground, with allowance for ample ſlopes to prevent ſlipping or its waſhing down by the waves: it will alſo be proper, for enſuring ſtability to the work, to reduce the whole of the top of the work to one level as K L, as ſoon as can be, by ſucceſſive layers of ſtuff thereon, and of puddle in the ditch *a e f b*, and round the well N M: and, if the bottom of the reſervoir will require lining, owing to the poroſity of the ſoil; it will be right, after levelling and treading the part *b* R perfectly, to cover the ſame with 3 or 4 courſes or linings of puddle, joining the ſame perfectly with the puddle-ditch, and the puddle round the well, to which courſes of puddle the bottom lining is afterwards to be carefully joined; and after this is properly ſet, the remainder of the bank L H I E, and of the cone O P Q R, may be proceeded with, as we have before mentioned, when treating of the rearing of canal banks with puddle-ditches in them. The bank or head being completed to H I, and the well N M, and conical embankment O P Q R, being alſo carried up to the proper height, the well ſhould then be coped with a layer of the beſt hewn ſtones cramped together, and the top reduced to a perfect level; and for ſecurity, it will be right to pave the ſurface of the top P Q, and for ſome diſtance down the ſides of the conical embankment, with paving ſtones pretty well jointed, and ſet their longeſt way into the ſoil, filling their joints with mould, and ſowing graſs-ſeeds therein, to prevent the waves from afterwards looſening the ſtones or wearing the bank; this conical bank is for enabling the water to fall into the well on all ſides; if the well was made in a corner of the reſervoir, much digging would be required, both for the arch or pipe to let out the water, and for the diſcharging arch D M.

We have been thus particular in deſcribing the circular weir or well-fall above recommended, from having ſeen the beneficial effects of one, in the reſervoir for Worſley mills near the duke of *Bridgewater's* canal; and the miſchief that is ſometimes done to the banks of a reſervoir and the adjoining lands, by letting off the flood-waters by common weirs or tumbling bays at the corners of the reſervoir, and ſuffering it to find or rather tear its own way down into the valley. Reſervoirs conſtructed on the above principles would be ſecure almoſt from accident, however high the embankment, or ſudden and copious the floods, if the well is but made ſufficiently large, and deep of water at the bottom, to receive the ſhock of the deſcending column of water. If the floods are ſo conſiderable as to bring down timber and other large floating matters, it will be neceſſary to fix a ſtrong grating or circle of bars round the top edge of the well bank P Q. It will ſometimes happen, that a reſervoir is over or near to the navigable tunnel of a canal, and might be let down into the ſame by a pipe and cock as at Ripley on the *Cromford*, and near Braunſton on the *Grand Junction*. It will be proper, that the core or plug of the cock to a reſervoir ſhould be turned by an endleſs ſcrew, or by toothed wheels, ſo that conſiderable power and nicety in the adjuſtment of the ſtream let out, by the turning of the cock, may be attained; and a regiſter ſhould be provided of the number of turns, and fractions of a turn, that is given to the winch or handle in any caſe. It will be proper to flanch on a ſmall pipe to the large one, and connect the ſame with an inverted glaſs ſyphon filled with mercury, in the arch near the well, ſo that by turning a cock, the height of the mercury ſhould indicate on a ſcale attached, what depth of water there is in the reſervoir above, or how much it wants of being full at the time. A ſeries of accurate experiments ſhould be made, by gauging the ſtream of water at D, or at the firſt convenient place below it, which the cock diſcharges per hour or day, when the water is at different heights in the reſervoir, and with different turns of the cock-geer; theſe ſhould all be repeated, and ſufficiently numerous, to enable the engineer by interpolation, to fill up and form a table, (that the committee ought carefully to preſerve copies of) by which at any given height of mercury, the cock can readily be ſet to diſcharge any number of locks full of water that may be required per day. No great difficulty would attend the forming of a gauge-puddle, inſtead of, or by the ſide of the braſs cock that ſhould regulate itſelf, and diſcharge any regular and conſtant quantity of water that the reſervoir could ſupply: ſee *Leybourn's Repoſitory*, 8vo. queſtion 81, p. 165. It will be right alſo for the engineer and committee, to have tables for readily ſhewing the quantity of water that every reſervoir contains, at each foot or ſhorter portion of its depth, indicated by the mercury in the ſyphon, or by a graduated gauge-poſt fixed up in any part; for forming a table of this ſort, where a complete ſurvey had not been made or preſerved at firſt, the time of a hard froſt ſhould be choſen, and a ſufficient number of holes at equal diſtances, in a great number of parallel or equidiſtant lines, ſhould be bored or cut through the ice ſufficiently large to let down a plummet to ſound the depth, and if this is done with care when the reſervoir is full or nearly ſo, a moſt correct table of its content at different depths, can be thus obtained by calculation. Some of the conſiderable reſervoirs that have been conſtructed for canals are, at Aldenham, Daventry, and Wilſtone on the *Grand Junction*; Kilſyth on the *Forth and Clyde*; Branſtone, and Denton on the *Grantham*; Ripley on the *Cromford*; Amſworth on the *Nottingham*; Littleborough on the *Rochdale*; Marſden on the *Huddersfield*; Oxendon on *Leiceſterſhire and Northamptonſhire Union*; in Rudyerd vale near Leek, for ſupplying the Caldon branch of the *Trent and Merſey* canal, which covers 160 acres, has its head 30 feet high, and the water in general very deep. St. Ferriol's reſervoir, conſtructed about the year 1670, on the canal of *Languedoc* in the ſouth of France, occupies a ſpace of 595 acres, its banks are walled round with free ſtone, and its waters let out when wanted, by a large pipe and cock.

In *conſtructing Feeders* or channels to convey water to a canal from ſprings, brooks, or reſervoirs above its level, the ſame care muſt be taken to examine the nature of the ſoil in every part, and to apply a lining of puddle, as have before been mentioned reſpecting the line of a canal, wherever porous ſtuff is to be cut through. Where there are a great number of undulations in the ground, through which a feeder is to be conducted, that would occaſion it to be very crooked and much impede the cultivation of the land, it will be proper, in many inſtances, eſpecially if the land be valuable, to cover over the feeder in a culvert or ſmall arch of bricks, of 18 inches or 2 feet diameter, or larger if the ſupply ſhall at any time require the ſame: in very porous ſoils, theſe culverts, incloſed in puddle, will be the moſt effectual way of preſerving and conducting ſmall ſtreams of water, and no land will thus be loſt to cultivation. In ſome places, feeders will require conſiderable embankments and aqueducts, to croſs valleys and ſtreams of water, and preſerve their level, or gradual and ſmall fall; and in many of ſuch caſes it will be cheaper and better to uſe caſt iron-pipes well jointed and flanched, and laid within the ground, down one ſide or bank of the vale to be paſſed, and up the other, ſecuring each end carefully with a ſtrong box full of holes, or a fine grating to keep extraneous matters out of the pipe. In the caſe of ſmaller feeders, particularly thoſe temporary ones, which are required to ſupply water to puddle with, and to fill the bottom of the canal for the temporary uſe of dirt-boats while making it, as before mentioned, elm-pipes in ſhort lengths, in which the moſt crooked arms of large trees will come into uſe, may be advantageouſly uſed in croſſing hollow roads, or other ſudden ravines, if the ſame be jointed by ſhort hollow double cones of caſt iron as recommended by Mr. *Hornblower*: ſee *Repertory*, vol. x. p. 25. It has often happened, where reſervoirs are ſituate at ſome diſtance above a canal, and a brook-courſe led from the reſervoir to the canal, that the water was left to take its ancient courſe on being let out of the reſervoir; an expert engineer will, however, carefully examine all ſuch feeders, for thus they ought to be conſidered, and fill up all deep holes, and lower the ſhallows in the brook-courſe, ſo as to reduce the channel nearly to an uniform width and depth; and very accurate gauges of the water ought to be made at different ſeaſons of the year, of the quantity iſſuing out of the reſervoir arch, and the quantity received into the canal; if theſe differ materially, intermediate and comparative gauges ſhould be made of the ſtream, until the faulty or leaky ground is diſcovered, probably ſome ſtratum of ſand or open-jointed rock; over which the brook-courſe or feeder ought to be carefully lined with puddle; and, if puddling-ſtuff be ſcarce, the ſoil very porous, and the brook-courſe very crooked, it may be the moſt effectual way, as well as the cheapeſt in the end, to paſs ſuch leaky ground by a ſmall culvert, incloſed in puddle under ground, by the ſide of the brook-courſe, as ſtraight as the courſe of the valley will admit. Except in ſituations, where mills in the vicinity of an intended canal are much in want of water, or their owners or others diſpoſed to thwart the ſcheme, it has been uſual to allow the company to ſearch for, and divert to their uſe all ſprings of water, within certain limits on each ſide of their line; in the acts for the *Newcaſtle underline Junction*, the *Southampton and Saliſbury*, and the upper part of the *Tamer Manure* canals, this limit is fixed at 1000 yards; in the *Aberdeen*, *Polbrook*, *Tamar Manure* lower part, *Thames and Medway*, *Wilts and Berks*, and others, this is fixed at 2000 yards on each ſide of the line. In ſuch caſes, an accurate inveſtigation and knowledge of the *Strata*, upon Mr. *Smith's* principles, will be of the moſt eſſential importance, in order to collect and retain ſprings that are above the ſummit level, or even in lower ſituations, where a local trade is to be provided for. It has been uſual in ſome mining diſtricts to require, that engines near an intended canal ſhould lift their mine-water into ſuch canal, or high enough to be conducted into it by a feeder, as on the *Birmingham and Fazeley* canal. It will be worth conſidering, on a ſummit, where water is ſcarce, whether a tunnel may not be more eligible than deep-cutting, on account of large ſprings which would be interſected by the lower level of the former, when the deep-cutting muſt perhaps be in porous ſtuff, or perhaps in dry open rock. As the ſummit pounds or levels of moſt canals are in deep cutting, through a conſiderable portion of their lengths, it is often attended with but little additional expence, except in the caſe of tunnels, to make ſuch ſummits pounds one or two feet deeper in water than uſual, as on the *Derby*, *Cromford*, *Mancheſter Aſhton and Oldham*, *Oxford*, and other canals, in order that ſuch additional depth, being filled in winter-time or wet ſeaſons, may act as a reſervoir for drier ones; but it has not always been conſidered, that ſuch deeper pounds, when filled 18 inches or 2 feet fuller than is neceſſary, occaſion the neceſſity of letting off twice that extra depth of water, over the area of a lock, each time that a veſſel paſſes the ſummit; by which, ſuch reſerve of water is in a great meaſure diſſipated before the dry ſeaſon for which it was intended arrives. We ſhould recommend, either the uſe of reſervoirs, ſo much above the ſummit level of the canal, that they could be emptied into the ſame, when the continuance of dry weather required it; or, if ſuch deeper ſummit pounds be made, on account of their conſiderable length for holding water, that a lock capable of penning 18 inches or 2 feet, and of ſhutting very tight, ſhould in ſuch caſe be built, near each end of the ſummit, to be uſed as long as the ſummit water is higher than uſual, but which might at other times be left open, when the water was level on each ſide of them. Before we quit the ſubject of ſupplying a canal with water, we beg to mention, that it may be worth the while of the engineer, where water is to be pumped up to ſupply the lockage, as we have before mentioned, to deſign and calculate the expence of wind-machines, capable of doing the required work, and of the probable expence of their repair; and to compare the ſame, with the coſt of erection, expence in fuel, attendance and repairs, of well conſtructed ſteam-engines to do the ſame work.

On the *erection of Aqueducts* for conveying a canal over any very deep and wide valley, or over a large or navigable river, we beg to mention, that a moſt ſecure foundation muſt be ſought for, by ſinking, or obtained by piling, for the piers of an aqueduct-bridge, and that the arches ought, in every caſe, to be arches of *equilibrium*, becauſe the leaſt ſettling in brick or ſtone bridges, by letting through the water, may prove of the moſt fatal conſequence. That the plan of an aqueduct-bridge ſhould be curving inwards, that is, the ends ſhould be wider than the middle, the walls ſhould alſo not be upright, but buttering or diminiſhing upwards withoutſide, to give greater ſtrength and ſtability to the whole; the materials, if of ſtone or brick, and the cement, ſhould be of the very beſt quality, and the work executed in the ſummer ſeaſon only. In *Plate II. Canals*, *figs*. 19, 20, and 21, we have given a plan, ſection, and elevation of an aqueduct-bridge, proper for croſſing a conſiderable river, where, in *fig*. 19, A is the river, B the canal, C the towing-path, and D D the wing-walls, for keeping up the embankments at each end of the bridge: in *fig*. 20, C is the towing path, and *a a* a lining of puddle to ſecure the canal B from leaking. Care ſhould be taken that all the joints of brick or ſtone are worked as cloſe as poſſible in an aqueduct-bridge, and thoroughly filled with cement; the ſlopes within ſide, and the bottom for the canal, ſhould be made rough, that the puddle may the better adhere to them, and that the puddle may not ſlip, owing to the ſteepneſs of the ſides, which muſt be more ſo than in other parts of the canal, to avoid unneceſſary expence of maſonry or brick-work in the width of the bridge. The lining as above is, however, liable to be ſoon cut away by the barges. Since the year 1795, a new kind of aqueducts has been introduced into this country, compoſed partly of caſt-iron, which promiſes the greateſt advantages, except, perhaps, where free-ſtone of an excellent and durable quality is found upon or very near to the ſpot, or where the ſame is very diſtant from any iron mines, or exiſting navigations that connect with ſuch. In the year 1797, Mr. *Thomas Telford*, the engineer, wrote an account of the inland navigation of the county of Salop, which has ſince been printed in J. Plymley's Report to the Board of Agriculture, on the Agriculture of Shropſhire, and we beg to extract therefrom what he ſays on this ſubject when ſpeaking of the *Shrewſbury* canal, p. 299, as follows: "This canal paſſes over the valley of Tern, at Long, for a diſtance of 62 yards, upon an aqueduct made all of caſt iron, excepting only the nuts and ſcrews, which are of wrought iron; and I believe this to be the firſt aqueduct for the purpoſes of a navigable canal which has ever been compoſed with this metal. It has completely anſwered the intention, although it was foretold by ſome, that the effects of the different degrees of heat and cold would be ſuch as to cauſe expanſion and contraction of the metal, which not being equal to extend or draw back the whole maſs of the aqueduct, would operate upon the ſeparate plates of iron ſo as to tear off the flanches which connect the plates lengthwiſe, and break the joints. Others ſaid, that the expanſion of freezing water would burſt the ſides, and ſo break off the flanches which connect the ſides with the bottom plates: but after the trial of a ſummer heat, and the very ſevere froſt of the winter of 1796, no viſible alteration has taken place, and no water paſſes through any of the ſide or bottom joints. After the froſt had continued very ſevere for three or four days, and the water had not been drawn off (although there are means of doing ſo), but it had ſtood in the aqueduct above the height of two feet ſix inches, the ice had then frozen to the thickneſs of an inch and a half, but inſtead of having forced out the ſides, it was melted away from them, and quite looſe upon the ſurface of the water. The idea of having this aqueduct made of caſt iron was firſt ſuggeſted and recommended by *Thomas Eyton* eſq. then chairman of the committee: after due conſideration, it was approved by the committee, and the principles of conſtruction, and the manner in which it ſhould be executed were referred to Mr. *William Reynolds*, and the writer of this article, (Mr. *Telford*) who, after ſeveral conſultations, and forming and conſidering various plans, at laſt determined upon that which is repreſented by the annexed engraving, (*Plate III. Canals*, *fig*. 22.)

"The caſtings for the aqueduct were done at Ketley, and were removed to Long, a diſtance of five miles, partly by land and partly by water-carriage. This aqueduct was propoſed in conſequence of the great floods which happened in the beginning of the year 1795, and it was fixed up complete in March 1796." Mr. *Robert Fulton*, an American engineer, who happened to be in this country at the time, ſeems to have availed himſelf of what was going on at Long aqueduct as above, and of the machinery of various kinds, in uſe upon the *Ketley* and *Shropſhire* canals, and to have prepared drawings and models of a variety of ſuch machinery, with many improvements of his own, and ſubmitted the ſame to the examination of a committee of the Board of Agriculture, in March 1796. Theſe have ſince been publiſhed in a handſome quarto volume, entitled, *A Treatiſe on the Improvement of Canal Navigation, by R. Fulton*, from which, p. 114, we beg to extract what he ſays on conſtructing aqueducts of caſt-iron for a narrow canal as follows: "The butments and piers being raiſed, it will only be neceſſary to extend two pieces of timber acroſs the ſpan; each to be braced back to the piers, and covered with plank to form a ſtage or ſcaffolding which will anſwer every purpoſe of centres neceſſary to works of ſtone. The iron-work, as in the ſection (*Plate* III. *Canals*, *fig.* 23 *and* 24.) may all be caſt in open ſand, and of the following dimenſions: ſuppoſing the ſpan 100 feet and the ſpring one-ſixth of the ſpan. Firſt, three ſegments of a circle, each in three pieces, about 36 feet long, eight inches by four diameter, to be united, as at A. Second, three ſtraight bars, to extend from one pier to the other, to be of the above diameters, may alſo be caſt in three pieces, which bars are to extend along the top of the ſegments to the piers, and form a line parallel to the horizon; the bars and ſegments to be united by perpendicular ſtirrups like B, ten or fifteen feet diſtant from each other. The mortice in the lower end of the ſtirrup being thirteen inches long, will be ſufficient to ſecure the ſegment, and leave room for a hole two inches ſquare, through which a croſs brace, C, is to paſs, and faſten the ſegments at proper diſtances; the brace to have a mortice caſt on each ſide of the ſtirrup, in order to tighten the work by wedges. On the top of the ſtirrup, the ſquare hole to receive the croſs brace may be beneath the mortices, as in the figure; by which means the whole may be combined, and form an iron ſtage to ſupport the troughs. The trough plates ſhould be at leaſt one inch thick, the ſide plates ſix feet broad, and as great a length as can conveniently be caſt; which may be performed twelve feet, and perhaps more in length: the flange to be outſide on theſe plates. The bottom plates may be ſix feet wide, thirteen feet long, ſeven feet plate, and four arms projecting, each three feet long, in order to ſupport the horſe-path and braces, as exhibited at D. Two of theſe plates laid acroſs the ſtage, and ſcrewed together, with a flange under, will compoſe a length equal to one of the ſide plates, which may either meet or break joint as is thought proper. The whole may, in this manner, be ſcrewed together, on packing of wool and tar, and have the ſeams pitched like thoſe of a ſhip. On the plates compoſing one ſide of the trough, ſmall brackets, about three feet from the top, muſt be caſt, as at E, in order to ſupport the horſe-path; perpendicular rails, eight feet long, being raiſed from the arms of the bottom plates, will ſupport the outſide of the horſe-path, alſo the iron railing, as in the ſection. By this mode, two patterns will anſwer for the whole of the trough-plates, and but few will be required for the ſprings, rails, and ſpurs; while the ſaving in time and expence will be conſiderable; particularly where it is neceſſary to bring the ſtone by long land carriage; for the arches being diſpenſed with, and the piers not more than one third of the dimenſions neceſſary to an aqueduct of ſtone, will moſt materially reduce the quantity of maſonry." "In aqueducts of ſtone, one of the great difficulties is to line and puddle ſo tight as to prevent the water penetrating into and injuring the maſonry; but in one of iron, ſhould a leak take place it will inſtantly appear; and on ſhutting the ſtop-gates at each end, and diſcharging the water, it may be ſtopped in a few hours, if not minutes: this circumſtance in aqueducts is, perhaps, one of the greateſt preſervatives; they are conſequently leſs liable to injury, and only ſubject to the corroding tooth of time."

Since the above period, a moſt ſtupendous work of this kind has been undertaken by Mr. *Jeſſop*, on the *Elleſmere* canal, and is now nearly or quite completed, for croſſing the Dee river at Ponteyſyltee, about 20 miles S.W. of Cheſter; where nineteen maſſive conical pillars of ſtone, at fifty-two feet from each other, the middlemoſt of which is no leſs than 126 feet in height, ſupport between the top of every pair, a number of elliptical caſt-iron ribs, which by means of uprights and horizontal bars, ſupport a caſt-iron aqueduct about 329 yards long, 20 feet wide, and ſix in depth, compoſed of maſſive ſheets of caſt-iron, cemented and riveted together, having on its ſouth ſide an iron platform and railing for the towing-path. In May 1796 Mr. *James Jordan* took out a patent for ſuſpending aqueducts from ribs of caſt-iron above them, in the ſame manner as his ſuſpended iron bridges. See *Repertory*, vol. vi. p. 230. Among the moſt conſiderable aqueducts of ſtone or brick are thoſe at Lancaſter on the *Lancaſter* canal, for a deſcription of which ſee our article BRIDGE. At Kirkintolluch and at Kelvin on the *Forth and Clyde*, Chirk on the *Elleſmere*, Marple on the *Mancheſter Aſhton and Oldham*, Monk-bridge on the *Trent and Merſey*, Whaley-bridge on the *Peak Foreſt*, Avoncliff and Dundas on the *Kennet and Avon*, &c. while at Burton on *Bridgewater*'s, a navigable river is paſſed, and near Wigan on the *Leeds and Liverpool*, another canal (the *Lancaſter*) is paſſed upon aqueducts. It was thought a bold and viſionary ſcheme by many, which Mr. *James Brindley* propoſed, of croſſing the *Merſey* river at Runcorn Gap, by an aqueduct bridge, but no doubt he could have accompliſhed it.

The *making of Embankments* appears to have been long practiſed in China, where we read of parts of their canals of 200 feet wide, that are embanked 20 feet high, for great lengths together; the rivers through the fens of Cambridge and Lincolnſhire in this country, have alſo been long confined thus, by artificial banks. Moſt of the aqueducts of which we have been ſpeaking above, have leſs or greater lengths of ſolid mounds or embankments for forming the canal upon, to the proper height, and for joining them to the aqueduct bridges; all the obſervations and remarks which we have made, reſpecting the ſetting out and aſcertaining the dimenſions of the head of a reſervoir, will apply to embankments; except that a priſm whoſe baſe is the figure G H L M N O I, *Plate* IV. *of Canals*, *fig.* 25, and length A B, *fig.* 16. *Plate* I. is to be deducted from the triangular embankment D G F, firſt to be calculated, inſtead of the triangular priſm G H I. The angle of the ſlopes ought to be determined by the reſult of ſimilar inquiries, and the ſame precautions uſed to prevent ſlips, in ſoils that are ſo diſpoſed, as were mentioned reſpecting reſervoir heads; it will generally be a ſafer way to carry up a puddle-ditch in each bank of the canal, as *a e*, *b f*, *fig.* 25, than to truſt only to lining of the canal L M N O. In every conſiderable embankment there will be required one or more arches to convey a brook or river under the canal, and, perhaps, others for roads to paſs through; ſuch arches ſhould always have an inverted arch turned below them, deep enough for the bottom of the brook, and below the roads, and the arch itſelf ſhould be one of *equilibration*. To avoid making a very large arch for a brook or ſmall river, it is uſual to make a road or communication arch near it, with its bottom well paved, and no higher than the ſurface of the meadows, which will ſerve to vent the ſudden flood in rainy ſeaſons.

Great care ſhould be taken to ſlope off and finiſh the ends of arches under an embankment, agreeable to the ſlopes or ſides of the banks thereof; by which the banks are prevented from mouldering down into the brook or road-way, and awkward projections in the ſlopes of the banks are avoided: at the entrance or upper ſide of a water-arch, or of road-arches that will occaſionally become ſuch, return or wing-walls of brickwork or ſtone ſhould be made, for ſome diſtance along the bottom of the ſlope of the embankment, and the ſharp corners of the entrance of the arch ſhould be a little rounded off, to prevent the rapidity of ſudden floods from wearing or injuring the bank. It is to be obſerved, in conducting a canal along the ſide of a ſteep and high hill, as *Plate* I. *fig.* 3, that after a certain degree of ſteepneſs of the ground A′ P′, it will not be poſſible to cut the canal, upon the principle that the excavation E F G I K P ſhall juſt form the bank A B C E, but ſuch banks will often require ſtuff to be provided from other places, and ſuch are indeed caſes of embankment: and here it may be proper to adviſe, that new banks, as A B C E, ought not to be placed on very ſteep ground, as A E, without conſiderable care in firſt forming it into levels like ſteps, to prevent the ſlipping of the new part, as happened near Bradford on the *Kennet and Avon* canal, after all the care that was taken, and great lengths of the canal banks ſlid down into the *Avon* river below, the making of which good again coſt, we were told, near 1000l. Among the conſiderable embankments that have been made for canals, are thoſe at Bollin and Stretford on *Bridgewater*'s, and Wolverton, Weedon, and Bugbrook on the *Grand Junction*, &c. but the greateſt extent of high embankment known, is that in the valley of the Boyne, in the *Grand* canal of Ireland; and the higheſt bank in the world is alſo to be found on the ſame canal in the valley of the River Rye; it is above 90 feet high. We are told, that Mr. *James Brindley* uſed a kind of caiſſon of planks, in forming his great embankments, in which dirt boats were uſed, to bring ſtuff from the higher ground, that had been cut through.

We have next to ſpeak of *Safety-gates*, *Stop-gates*, and *Stop-planks*, which are different contrivances for ſtopping the water of a canal in caſe the banks are failing in any part, or that any part wants emptying to repair the works. Advantage is generally taken of the walls under the bridges, for conſtructing theſe contrivances, where the ſame happen in the proper places; otherwiſe the canal muſt be contracted by upright walls, the ſame as is done at the bridges on purpoſe for them. For explaining the nature of ſafety-gates, we muſt have recourſe to *fig.* 26, where A B is ſuppoſed to repreſent the top of the wall, or height of the towing-path under a bridge, C D the ſurface of the water, and Q S the bottom of the canal; E F G H is a pier of hewn ſtones, or a piece of ſound oak timber let into the wall, its face being fluſh therewith; I E G and H F K are receſſes about two inches deep in the wall; ſimilar proviſion is made in the oppoſite wall, for receiving doors or gates L M and N O acroſs the canal, turning on centres or hollow-quoins at M and N: each gate is ſo balanced by a counter weight, that they reſt always in the poſition repreſented: and they are intended to operate thus, ſuppoſe, owing to the ſudden breaking of a bank, the water in the canal ſhould acquire a current from Q towards S, the ſtream would paſs under the gate at P L, to facilitate which, the corner of the floor at P is ſloped off; the gate would be turned up into the poſition M E, and the canal would be thereby cloſed up. The like would happen by the other gate N O, in caſe of a current the contrary way. Safety-gates ſhould be placed at proper diſtances on every long level or pond of water, eſpecially if the ſame is much embanked; both to prevent the loſs of ſo much water, in caſe of a bank breaking, and the miſchief that the ſame would do to the lands, mills, &c. below the breach. We read of a new bank breaking on the *Warwick and Birmingham* canal, and deſtroying a gentleman's park-walls; and in the year 1783 ſo great a breach ſuddenly happened on *Bridgewater*'s canal, near London bridge on the Cheſter road, that three barges were carried through the ſame a great way out into the fields. A ſingle ſafety-gate ought to be placed at the end of every long embankment, to ſtop the water in caſe of a breach happening in its banks. *Stop gates* are ſimilar in their conſtruction to the ſafety-gates above deſcribed, except that the gate lies flat on the bottom of the canal inſtead of being balanced, and has a chain by which it can be hauled up, whenever occaſion may require the canal to be ſtopped. *Stop-planks* are a ſimple, though not ſo expeditious a proviſion for ſtopping a canal as the laſt; a groove is provided in the two oppoſite walls under a bridge, or in a narrow and walled place, and a ſufficient number of well jointed planks are provided, to be dropped into the groove whenever the water is required to be ſtopped, and hence theſe are often called drop-planks. In very large works like the *London docks*, a barge or veſſel is built in the place, whoſe head and ſtern poſts exactly fit into a groove as above, and the veſſel can be floated into and out of its place, or ſunk therein as occaſion may require. The engineer will alſo have to make proviſion, while the canal is digging, for *ſtop-bars* at the ſeveral intended toll-houſes, or other places where it may be neceſſary to ſtop barges in the night, or in caſe of any diſpute about their lading: theſe bars are compoſed of a large baulk of fir timber floating on the water; and a ſmall arch capable of containing ſuch a floating beam of the proper length is provided under the bank, ſo that when the trade on the canal is required to be ſtopped, the toll-clerk has only to draw out the beam by means of a cord attached to it, until its end enters a receſs in the oppoſite wall, and then to lock the beam faſt.

We ſhall next deſcribe the *Waſte-gates*, *Trunks*, *Tumbling-bays*, or *Weirs*, that muſt be provided, for letting off the ſufluous water of a canal in wet times, for keeping the water to one certain height, or drawing it off in caſe any repairs may be wanting. *Waſte-gates* are ſluices of the common conſtruction in the ſide of a canal, where any conſiderable quantity of water is required to be let out, and are to be drawn up, either by a rack and pinion, a chain and roller, or a number of holes for a crow-bar, as circumſtances may render moſt eligible: where leſſer quantities of water are to be let out, or for emptying certain lengths of the canal between the ſtop-gates or planks, when occaſion may require; *trunks* formed of oak or elm planks, well jointed, ſhould be laid into the bank, at the bottom of the canal, and carefully incloſed in puddle, with a valve or ſhuttle that will ſhut very tight, and can be readily drawn when the water is required to be let off: we beg to recommend, wherever wooden trunks are uſed for any ſuch purpoſe, that they ſhould be ſunk ſo low, or the mouth where they diſcharge ſhould be made up, ſo that the trunk may always remain quite full of water, and the air be at all times excluded; in which ſituation wood will laſt much longer than if wet and dry alternately.

In the choice of ſituations for *weirs*, to diſcharge the ſurplus water of a canal, care muſt be taken not to let off any conſiderable quantity at any time, but into a brook-courſe or bottom of a vale, that is croſſed or proceeds up to the canal, and has ditches through which the water can eſcape, without tearing or doing injury to the land adjoining. The moſt frequent *tumbling-bays* or *weirs* to diſcharge water from canals are compoſed of ſtrong walls of brick or maſonry, as *q c*, *Plate* IV, *Canals*, *fig.* 27, whoſe top *q* is coped with hewn and well jointed ſtone, or with a ſtout ſill of oak, the top of the ſame being juſt level with the top-water line *q* D H, or about one foot lower than the top-bank D C I K, A *c* is a paving of large ſtones for the water to fall on, and eſcape at A, and A B *c* are wing-walls at the ends of the weir, to keep up the bank and confine the water. Theſe weirs are generally on the towing-path ſide, on which a low plank bridge, as C *l*, is ſupported over it, called a weir-bridge. When theſe weirs are wanted of conſiderable length, the wall *q c* ought not to be ſtraight but on a circular plan, curving inwards in the middle, by which it will be better able to ſupport the lateral preſſure of the bank behind it; a puddle ditch ſhould be carried up immediately behind the wall, allowing the courſes of puddle to ſet thoroughly, before others are applied, that the great preſſure of the ſemifluid puddle may not overſet or diſturb the wall; and the paving AC ſhould be of large and well jointed ſtones, and if ſet upon a courſe of puddle it would be a further ſecurity againſt their waſhing up, which too often happens. We have ſeldom ſeen any conſiderable weirs or tumbling-bays of the above conſtruction, but where it would have been better to have followed the example of Mr. *James Brindley*, on *Bridgewater*'s canal, and have made a *circular-weir*, or well-fall, on the upper ſide of the canal; we have ſpoken of theſe when treating of the general improvement of a valley, as alſo in the making of reſervoirs, but it may be proper here to refer to a ſection of ſuch a well fall in *fig.* 28, where A′ P′ is ſuppoſed to be the ſection of a vale croſſing the canal C F G I; A M is an arch of brick-work, ſecured on its upper ſide at leaſt, with a covering of puddle, and M N is a well, whoſe ſteining or lining of brick or ſtone is groined into the arch at M, having a well paved floor, three or four feet below M, according to the height N M that the water is to fall, and a coping of hewn ſtone, or a large curb of ſound oak at its top. I O P Q R P′ is intended to repreſent the ſection of a ſide pond or wider place in the canal, from which the water may drop quietly into the well at N from all ſides, and run off at A.

For letting a proper quantity of the ſurplus water of a canal forwards into the ponds below, a ſmall weir is generally conſtructed in the walls at the head of each lock, which lets the water down into the paddle-holes, or crooked arches that convey the water for filling the locks, and hence ſuch are called *paddle-weirs* or lock-weirs. The upper gates or doors of the locks are often boarded no higher than the top-water line, and therefore act as weirs for diſcharging ſurplus water into the lock; and gates of this ſort are called *flood-gates*.

On the *conſtruction of Culverts*, or drains under a canal for conveying away water from the upper to the lower ſide of the canal, it remains for us to ſay, that they ſhould be carefully apportioned in ſize to the ſtream that is to paſs through them in floods, and ſhould be conſtructed of ſound brick or ſtone work, and incloſed, or at leaſt well covered on their upper ſide with puddle. Many engineers have uſed wooden trunks for this purpoſe, but except wood be in great plenty, and of the beſt quality, and good bricks or ſtone very difficult to be procured, it is not adviſable to uſe periſhable materials in ſuch ſituations. If the ground be moory or bad, and a culvert muſt lie pretty near to the bottom of the canal, and have but a ſlight covering, it may be proper, in ſome ſituations, to uſe caſt-iron cylinders flanched together, as was done under or near the *Staffordſhire and Worceſter* canal; and ſuch may be made cheaper and eaſier of carriage, by being in two or three ſegments longitudinally. to be flanched together before they are laid down; and in ſuch ſituations, perhaps leaden rivets might be cheaper and be more durable than wrought iron ones, or nuts and ſcrews. If bricks are to be uſed in culverts, over ſoft and moory ground, or quick-ſands, a cradle compoſed of ribs of wood and boards or rails, ſuch as are uſed for centering, ſhould be prepared, ſuitable to the outer curve of the intended culvert, and ſuch a cradle ſhould be carefully embedded, in the proper place to receive the bricks of the lower ſegments of the culvert: for want of ſuch precaution many a culvert has ſunk partially, perhaps owing to the ſprings excavating the ſand or filth from below, and has been broken, to the great injury of the canal. Culverts are of ſo much importance, that too much care can hardly be taken to make them ſolid and ſecure, and to cover them effectually with puddle: another hint we would here give, reſpecting the choice of places for the culverts; they ſhould never, if poſſible to avoid it, be made exactly in an old brook-courſe, ditch, or ſlough, but in the neareſt ſound ground; and where often they can be got down to the proper depth, without any trouble from water, or at leaſt the ſame can be eaſily pumped out; and the ſtream need not be admitted to the work, until the old brook or ſlough is required to be filled up. In this way it often will happen, that culverts may remain during the winter following their conſtruction, completely excluded from the froſt, and therefore may be done later in the year, by filling in the ſtuff upon them and at their ends, and the mortar be completely ſet before the new channel at the ends for conducting the water through them need to be cut. And we beg to remark, that by an attention to this circumſtance in making new arches under roads, and keeping the bottom of the arch much lower than is generally done, or indeed practicable in the old channel or ſlough, half or two-thirds of the whole expence will generally be ſaved; for a deep and new channel being cut to the new arch; with ſcouring out the brook-courſe for ſome diſtance below, old ford-places, if the deſcent to them be eaſy and convenient, will not require immediately to be filled up or altered; but during any extraordinary flood, the ſame, if compoſed of gravel and hard ſtuff, may act the part of a weir for a ſhort time, in carrying off the water, without injury to the road or material inconvenience to the paſſengers. It will ſometimes happen, that a ſmall ſtream of water is required to paſs under the canal, in places where it is not embanked; in ſuch caſes a crooked or *broken-backed culvert* is to be made, as *m o o n*, *fig.* 29, for paſſing the water from *m* to *n* under the canal C F G I; this will require puddling as before deſcribed, and a ſtrong box full of holes, or grating, ſhould be fixed over each of its ends, as well as pits or holes be made at the upper end, deeper than the mouth of the culvert, to receive and detain the ſand and gravel which the ſtream may bring down in haſty rains, otherwiſe theſe, or the ſtones that miſchievous boys might throw into it, would in time choak it up between *o* and *o*.

The *conſtruction of Tunnels*, or ſubterraneous arches, for drawing off or conveying of water, has been known from the earlieſt periods, as appears by the celebrated works of this kind between lake Copais in Bœotia and the ſea; between the lakes formed by the inundations of the Nile in Egypt and the Mediterranean; as alſo by the courſes of the Roman aqueducts, many of which were tunnelled through hills of great extent. In the mining diſtricts of this country, we have long had levels or audits of conſiderable extent to mines; in the neighbourhood of Matlock in Derbyſhire, the *Helcarr Sough* has been cut through the ſolid rock for nearly four miles in length, for the purpoſe of draining the ſeveral lead mines in the vicinity; *Wirkſworth Moor Sough*, of near three miles long, and *Cromford Sough*, of two miles in length, with many others of leſs note, are alſo to be found at great depths in that neighbourhood. The firſt *tunnel* that we read of, as conſtructed for the purpoſe of navigation, was by M. *Riquet*, near Bezieres on the *Languedoc* canal, in France; and the firſt in this country, was the entrance made by *James Brindley* to the duke of *Bridgewater*'s coal-mines at Worſley near Mancheſter; while the firſt of our tunnels undertaken for the purpoſes of general trade, or as a thoroughfare, was by the ſame engineer at Harecaſtle on the *Trent and Merſey* canal. It is very eſſential to the convenience as well as the beauty of a tunnel, that the arch thereof ſhould be quite ſtraight, and exactly level; conſiderable care will therefore be neceſſary in obtaining an exact ſection, by levelling, of the hill that is to be perforated, when a line in the exact vertical plane of the tunnel is fixed and ſtaked out over the hill; in doing which, it will be right to chooſe the narroweſt place that the hill preſents at the propoſed level, and where alſo the hill riſes rather boldly from ſuch level; otherwiſe an expenſive and troubleſome length of deep-cutting would be neceſſary, or of the tunnel that muſt be dug out from above and then covered up again, before a ſufficient depth of ſtuff over head would be come at, to admit of working under ground; it will alſo be of conſequence, when determining the exact line for a tunnel, to avoid having the deep-cutting and entrances in alluvial or diſturbed and ſlippery ſoils, but, if poſſible, to enter at once upon the ſolid and undiſturbed *ſtrata* of which the hill is compoſed.

It will but very rarely happen, and that only on ſhort tunnels, made for the purpoſe of preſerving the level of a canal, that the workings will not be in ſoil more or leſs full of ſprings of water; therefore one of the firſt operations, after the line and level of a tunnel is finally determined on, is to ſearch by levelling for a place in the neareſt vale or brook that is ſome feet below the propoſed level of the bottom of the tunnel; this muſt be more or leſs, according as the intended tunnel is of greater or leſs length; and from this point a large ditch muſt be opened, with a very ſmall riſe towards the end of the tunnel, as far as is practicable, and then a *heading* or ſough muſt be begun, juſt large enough for men who are uſed to ſuch buſineſs to work in, and to line it ſecurely with bricks as they proceed, but leaving proper openings in the joints for the ſprings to collect freely from all ſides into their heading. Some perſons have ſupported their headings with boards and props of wood, inſtead of arching them; but which practice we cannot recommend: all ſuch works ought to be durably conſtructed, or ſhould any accident or circumſtances, as the want of money, &c. delay the completion of the work for ſome years, all this tedious and expenſive work will perhaps require doing again; it ought alſo to be conſidered, that after ſome years or ages have elapſed, the tunnel may want repairs or alterations, and that the ſame headings may be again opened and uſed, to lay it dry in a ſhort time, if durably conſtructed; which may be of the moſt material conſequence in leſſening the period of interruption to the trade by ſuch repairs or alterations. It will be neceſſary to begin a heading as above-mentioned on each ſide of the hill, and work them up towards each end of the tunnel, along the line of which it is to proceed from each end, riſing gently as it advances towards the middle point, that the water may run freely off; the headings ſhould be a few feet below the bottom of the working, that will be neceſſary for the inverted arch of the tunnel, and a few yards off on the ſide of it; and croſs headings or ſoughs muſt, at ſtated diſtances, be run under the line of the tunnel, into which, openings can afterwards be made to let off the water which collects in each ſeparate working. If the ſoil be rather ſtiff, and the quantity of water in it not very conſiderable, one heading may ſuffice; but where porous ſtuff, with great quantities of water are interſected, it will be neceſſary to branch off an additional heading, to proceed along the other ſide of the line, the more effectually to draw off the water; by which, perhaps, if the headings are done a ſufficient length of time before the tunneling is begun, a quick-ſand, or ſimilar running of the ſtuff, may in ſeveral places be prevented. If in driving the headings, any fiſſures or cavities filled with ſand or looſe matters, are interſected, and are found to bring a conſiderable quantity of water from one ſide of the line, it may be right to drive a croſs heading for ſome diſtance into ſuch porous ſtuff, for intercepting the water before it reaches the intended workings of the tunnel.

The next operation will be to ſet out a line very truly parallel to the line of the intended tunnel, and to mark thereon, at equal diſtances, about 150 yards apart, or oftener if great expedition in completing the tunnel is required, the place of the ſeveral tunnel pits, that are to be ſunk for drawing up the ſtuff excavated from the tunnel, and letting down the centres, bricks, and other things wanted in the work; it will be well to contrive the line of the headings and tunnel-pits, ſo that they may coincide; and in great lengths of heading ſhafts or tunnel-pits may be ſunk at intervals, to give air to the headings, and through which the ſtuff excavated therefrom may more readily be drawn up; and it may be adviſable, in ſome inſtances, to ſet out a line on each ſide of the tunnel, for the tunnel-pits to be ſome on one ſide and ſome on the other of the tunnel, and that both may in places interſect the headings. If bricks or ſtones are not at hand when the tunnel-pits are begun, and wood is plenty, the ſhafts or tunnel-pits may be made ſquare, and have their ſides ſupported by boards and ſtruts of wood; otherwiſe they ſhould be made round, and lined or ſteined like a well as ſoon as they are done; if the ſoil ſhould prove looſe and full of water, it will be neceſſary to ſtein the ſhaft as ſoon as ſuch ſoil is reached, and to work afterwards from underneath the curb, and let the ſteining ſink, as is done in well ſinking. Some tunnel pits have been made over the line of the tunnel, but ſuch do not admit of being ſteined with ſafety, on account of the weight thereof, which would damage the crown of the tunnel, where they were groined into each other; and ſuch of them as are left afterwards for air ſhafts, if the ſoil is wet, will let an unpleaſant dripping of water down upon the goods or paſſengers in paſſing through the tunnel, as we once experienced in paſſing through Braunſton tunnel on the *Grand Junction* canal. A common roll and winch will be ſufficient for drawing up the ſtuff and water, and letting down bricks to ſtein with, unleſs the quantity of water is conſiderable; but it will be proper to erect a horſe gin, or turn beam, ſuch as are uſed at the ſhafts of coal-pits, for the cheaper and more expeditious drawing up the ſtuff and letting down of materials, when the workings have commenced. We have before recommended a line to be ſtaked out exactly parallel to the line of the tunnel for the centres of the ſeveral tunnel-pits, and care ſhould be taken that no gin, or other obſtruction, be erected in this line, ſo that a fine line or ſtring can at any time be ſtretched acroſs the top of any of the tunnel-pits, and be adjuſted without fear of miſtake in the exact range of this line, or parallel to the intended tunnel. When a tunnel-pit is completed and ſteined, and a communication formed with the heading to keep the ſame clear of water; two points muſt be fixed in the ſteining near its bottom, by letting fall or ſuſpending plumb-lines, at the time that there is no wind to diſturb their verticality, and adjuſting another fine line between the two points on the ſteining below, ſo as to be exactly under and parallel to the line above and conſequently ſo to the intended tunnel. The engineer ſhould carefully repeat his levels and transfer the level of the bottom of the intended tunnel, or the ſurface of the water of the canal therein, and mark the ſame carefully in the ſteining of each tunnel-pit: and thus the workmen who are to undertake the work will be furniſhed with the direction, level, and diſtance of the tunnel they are to form under ground.

The work commences, by excavating a paſſage from the tunnel-pit into the line of the intended tunnel, and ſupporting the ſame properly with timber, or walls and an arch, as a paſſage into the work. A piece of the intended tunnel, a yard or more in length, according as the ſoil is found to ſtand, is then excavated, in the proper form, place, and level, aſcertained from time to time by ſtretching a fine line between the marks, on the ſteining before-mentioned, and meaſuring therefrom, and uſing a common plummet level for transferring the level from the level-mark on the ſteining before-mentioned; great numbers of ribs for centerings ſhould be prepared in different ſegments, and in readineſs to put together with nuts and ſcrews, leaving as much room in the middle or centre as can conveniently be done, for the men to work and paſs through after the ſame are put up; the parts of two of theſe ribs are then to be let down the tunnel-pit, and to be put together and fixed up in their proper place and diſtance aſunder in the tunnel; ſhort lengths of boards or laths are to be prepared and fixed on their outſides, as the turning of the arch proceeds; which, as well as every other part of this very difficult work, requires the utmoſt care and experience to make it ſound and ſubſtantial; when this firſt yard or leſs in length of the tunnel is turned and ſecurely keyed up, the ſame is ſecured by ramming in clay, or proper ſtuff, ſo as to fill every cavity above or withoutſide the brick-work. The workmen then begin at each end of the piece that is turned, one party working one way along the line of the tunnel, and another the contrary way, until another yard or other length of the tunnel is excavated, when other ribs are put up and fixed together, boarded, and the brick-work is turned round or behind, the ſame as before; the utmoſt care being taken to joint theſe courſes evenly and ſecurely into the former ones: the vacant ſpace is then rammed up with earth, and a new excavation proceeded with at each end as before. The engineer ought frequently to renew his level-marks from fixed and good bench-marks on the ground, and to examine and adjuſt the ranging line, and alſo himſelf moſt carefully inſpect each working of the tunnel, and examine, by ſtretching a fine line along its centre, and meaſuring and levelling to his ranging line in the tunnel-pit, to ſee that every part of the work is proceeding exactly in the ſame line, and ſo that when in proceſs of time each adjacent working ſhall be joined, and the tunnel be completed, the whole may form one exact and truly ſtraight arch. If the ground proves looſe and bad for ſtanding, it will be proper to continue the work, by different ſets of men, without any intermiſſion; and care ſhould be taken that the work never is left, even for a night, without templets, or ſhort pieces of plank, being put up to cover the roof, that is neceſſarily left open to admit the men's heads and arms, while they are turning and backing up their laſt length of work at the crown; and theſe templets ſhould be ſecurely ſhored up by ſpars or ſtruts, to prevent the earth from ſettling or falling in, which has actually happened in ſome tunnels, owing to the neglect of this ſimple and neceſſary operation, ſo that a conſiderable length of the tunnel required to be dug out from the ſurface of the ground to repair the breach. When the tunnel and ends are completed, ditches are to be dug out, acroſs the headings, near the entrances of the tunnel, and a ſubſtantial puddle-ditch carried up, to effectually dam them up, and force the water that afterwards collects in them to riſe up into the tunnel, through croſs-headings, to be left for that purpoſe.

The tunnel at Bliſworth, on the *Grand Junction* canal being the lateſt that has been completed (Feb. 1805.) we have aſcertained the following particulars relating to it, in order to give ſome idea of the preſent ſtate and expences of tunnel making. The internal width of this tunnel is 16½ feet, the depth below the water-line to the inverted arch 7 feet, and the ſofit or crown of the arch is 11 feet above the ſame line. The ſide-walls are the ſegments of a circle of 20 feet radius, the top arch of one of 8 feet radius. The ſide and top walls are 17 inches, or two bricks thick, and the bottom or inverted arch 13 inches, or 1½ brick thick; every fifth courſe of the top arch, and every eleventh of the ſide walls, is compoſed of two heading bricks, or wedge-like, one inch thick on the inſide and three at the back; alſo, every fifth and eleventh courſe as above (but between the courſes of heading bricks) are compoſed of bricks laid obliquely acroſs the others, the front and back corners being cut off for that purpoſe in the making, for more effectually breaking the joints, of work obliged to be done in ſuch ſhort lengths. The mortar that was uſed, was compoſed of one buſhel of Southam lime (*blue lias*) and three of good ſand. Six inches under the water line, on each ſide of the tunnel, ſlide-rails of fir, 5 inches ſquare, to keep the barges off the walls, are fixed by pieces of oak let into the wall below them; which rails project 9 inches from the wall, and have at every 9 feet, a chock of wood upon the rail, for the bargemen to ſet their pole againſt for ſhoving their barges along. And we were told that this tunnel was contracted for, at 15l. 13s. per yard run; the ſoil principally a hard blue clay, with two or three thin rocks in it. Sufficient headings had been executed ſeveral years before at the company's expence. The ſame contractors were paid 10½d. per cubic yard for excavating the deep cutting at one end of this tunnel, and 11d. per cubic yard for the other. The expence of driving the above headings were, we underſtood, from 36s. to 42s. 6d. per yard run. Nineteen tunnel-pits, ſome of them 60 feet deep, were ſunk for the uſe of the above tunnel, which coſt about 30s. per yard in depth including ſteining. In our inquiries reſpecting Braunſton tunnel, on the ſame canal, we were told, that 320 yards of the ſame was drove in quick-ſands, and that it coſt 4800l. extra on that account. The Foulridge tunnel on the *Leeds and Liverpool* canal, of 1630 yards long, proved to be in ſuch very looſe and bad ground, that the whole of it, but about 700 yards, was obliged to be dug out from above; in ſome parts 30 yards wide at top, and near 20 deep, and immenſe works of timber were neceſſary to ſupport and keep the banks apart, while the tunnel was turned, and the ſoil filled in again. Some part of this work, done about the year 1794, coſt 24l. or more per yard run.

After a good length of the tunnel has been completed and well backed up, and been allowed ſome days or weeks for the earth to have ſettled regularly upon the brick-work, the centering may be removed, by looſening the ſcrews and taking it to pieces, to be again put up and uſed further on in the ſame working. In tunnels upon high levels in porous ſoils, and in others ſometimes near their ends, or in croſſing any dry and porous ſtratum, it may be neceſſary to excavate the bottom a foot or 18 inches deeper than uſual, and to fill the ſame up again with well wrought and ſtiffiſh puddle, and to turn the inverted arch, and as much of the ſides as are below the water-level, upon the ſame, when ſet. Mr. *William Chapman*, page 52 to 54 of his *Obſervations*, &c. before quoted, has given ſeveral directions for ſetting out tunnels, where coal-ſtrata are intended to be interſected and worked thereby, as at Worſley on *Bridgewater*'s, and Harecaſtle on the *Trent and Merſey* canals. It will be a matter of ſome importance, for the engineer to attend to the removing of the top ſoil from a ſufficient ſpace near each tunnel-pit, and to cauſe the ſame to be evenly covered, or the holes therein filled up, with the ſtuff that is drawn up and wheeled away from the tunnel-pits; and as faſt as the different parts of the tunnel are completed, reſerving ſtuff enough to fill up ſuch tunnel-pits as are not to remain for air-ſhafts, to cauſe the top-ſoil to be returned upon ſuch places, to avoid a heavy expence for ſpoil banks, beſides putting the farmers and neighbourhood out of temper by ſeeing the apparent waſte and devaſtation that ſuch works make, when careleſsly or negligently performed. The want of a towing path through a tunnel muſt be very apparent, to all ſuch as have ſeen the tedious and barbarous proceſs in uſe, of a man lying at length upon the gunnel of the barge, and pawing the walls with his feet; in narrow boats this is ſtill more evident, where a plank is obliged to be laid acroſs the barge for the men to lie down upon their backs, in order to be able to reach and paw the walls with their feet! The tunnel near Atcham on the *Shrewſbury* canal, though of 970 yards in length, has a towing-path through it; ſo has one at Newbold on the *Oxford* canal, and many other ſhort ones in different places. In all ſhort tunnels, and even in long ones, if the ground proves, on examination, ſound and good for tunnelling, it certainly would be worth while to give the neceſſary width to the arch, to admit of this eſſential appendage.

Among the moſt conſiderable tunnels that we have, are thoſe at Worſley on *Bridgewater*'s canal, 18 miles in length! Marſden on the *Huddersfield*, 5280 yards; Sapperton on the *Thames and Severn*, 4300 yards; Penſax on the *Leominſter and Kington*, 3850 yards; Laplat on the *Dudley*, 3776 yards; Bliſworth on the *Grand Junction*, 3080 yards; Ripley on the *Cromford*, 3000 yards; Dudley on the *Dudley*, 2926 yards; Harecaſtle on the *Trent and Merſey*, 2888 yards; Norwood on the *Cheſterfield*, 2850 yards; Weſt-Heath on the *Worceſter and Birmingham*, 2700 yards; Morwelham on the *Taviſtock*, 2500 yards; Oxenhall on the *Hereford and Glouceſter*, 2192 yards; Braunſton on the *Grand Junction*, 2045 yards, &c.

The longeſt tunnels that have been propoſed, beſides the above, were one of 5 miles on the once propoſed extenſion of the *Mancheſter Bolton and Bury* to the Calder river; and one of 4¼ miles on the *Portſmouth and Croydon*, through the chalk hills ſouth of the latter place. The towns of Mancheſter, Kidderminſter, and Southampton appear to be tunnelled under by the *Bridgewater's*, *Stafford and Worceſter*, and *Southampton and Saliſbury* canals reſpectively.

The *executing of deep-cuttings* appears to have been long familiar to the Chineſe, ſince we read of ſome of their canals that are in places excavated 80 feet deep! and of others that are cut 20 feet deep for ſeven or eight miles in length! The ſetting out and determining upon the ſlopes of a *deep-cutting* of conſiderable depth and length, are objects deſerving more of the engineer's attention, than has in too many inſtances been beſtowed upon them: the firſt ſtep, after the line and the level of the intended canal are determined upon, ſhould be to examine minutely the ſoil in every part that is to be cut in, and to prove the ſame by the ſinking of ſeveral ſhafts; if any of theſe, towards the centre of the hill, ſhould be found in looſe and porous ſoil full of water, while the ends of the intended cutting may appear to be in ſound ſtuff; it will be worth while, in ſome ſuch caſes, to put down pumps and erect a temporary ſteam engine, to pump up the water during the work, and to drive headings from ſuch pump-ſhaft, on one or both ſides of the intended cutting, and below its bottom, as has been before mentioned, preparatory to driving a tunnel. Should the whole of the cutting appear to be in looſe alluvial ſtuff, full of water, and diſpoſed to ſlip, or a part only of the ground at one end, as happened at the ſouth end of the deep-cutting near Tring, on the *Grand Junction* canal, it certainly will be right to begin ſuch part, by driving a heading up from a proper point below the intended cutting, and to give time for the ſprings to drain off before the cutting is begun, which may afterwards proceed in ſeparate lengths at the ſame time, and with much greater certainty and diſpatch, by the help of croſs headings, to drain off the water, than is practicable without ſuch precaution, unleſs expenſive and very powerful pumps or machines are uſed in the works to clear them of water in different places; while the tendency to ſlip is much increaſed by ſuch ſudden and partial drawing off the water. *Slips* are among the moſt formidable accidents to which canal-works are liable, and can hardly be too much guarded againſt, by giving an extra ſlope to banks in ſuch places, but particularly by driving headings behind ſuch parts, ſome time before the workings are begun, in order that the ſprings may be intercepted, by which the moſt porous and looſe ſtuff like quick-ſands may, in many inſtances, be converted to ſound and good ſtanding ſtuff. After all, where the *ſtrata* alternate very faſt, and have a conſiderable dip, and any ſlippery matter like fullers' earth or potters clay intervene, adjoining to a porous ſoil that can ſupply it with moiſture, it is almoſt impoſſible to avoid ſlips, that will prove moſt diſaſtrous in their conſequences, both in expence and delay of the works; as happened in the Tring deep-cutting above mentioned, on the *Glouceſter and Berkley* canal, and many others which we have heard of.

When the engineer has, by a thorough inveſtigation, as above recommended, aſcertained the nature of his ground, and its tendency to ſlip, he can determine what ſlope the upper banks A B and P K (*Plate* I. *Canals*, *fig.* 6.) ought to have in every part; for theſe ought not to be regulated by the ſlopes C F and I G, againſt which the water is to lie, and the waves of the canal to act, but be as ſteep as the ground or rock will ſtand, in every conſiderable length together; and the degree of the upper ſlopes will be liable to vary accordingly; if theſe are too much ſloped, a waſte of land and of labour in excavating and making ſpoil-banks will be occaſioned, while if they are made too ſteep in ſlippery or looſe wet ground, ſlips may happen that will occaſion ſtill more ſerious expences, and delay alſo. All theſe preliminaries being ſettled, and the width in every part calculated, a number of ſlope-holes muſt be dug at A and P, and a lock-ſpit dug out to join them, by a careful workman, as mentioned before on the marking out of the canal; and the top-ſoil being removed and clamped, from a ſufficient ſpace for ſtowing the ſtuff, the work will then be ready for the contractors to begin digging. This will be our proper place to notice ſeveral machines, and contrivances for aſſiſting the operation of excavating of canals, docks, or other deep-cuttings. The moſt ſimple and uſual method for ſmall depths is by runs of wheeling-planks, ſupported in an oblique direction up the ſide of the bank upon horſing-blocks of different heights, on which the labourers wheel out the ſtuff. In larger works, *turn-beams* or *horſe-gins* are erected on the bank, and a level-ſtage or ſcaffolding is erected over part of the deep-cutting; two ropes wind and unwind contrary ways off the drum or barrel of the gin, and paſs over pulleys fixed over the end of the ſtage; theſe ropes terminate in three ſmaller ones, two of which have at their ends rings, and the other a hook, of iron. When a loaded barrow arrives on the run below the ſtage, a labourer ſtands ready to ſlip one of the rings on to each of the handles of the barrow, and to hook the other end into the fellies of the wheel; when the revolution of the gin draws up the loaded barrow to the ſtage above, which a labourer lands, unhooks the three ropes, and affixes them in like manner to an empty barrow that is to be let down, while a full one is aſcending as before, by the other rope. The loaded barrows are wheeled away upon the ſtage, and run therefrom to any place above that is deſired. At the *London Docks*, we ſaw a very ſimple method uſed; two ſtrong poſts were ſet faſt into the top of the bank of the dock, at 40 or 50 yards from each other; and at about five or ſix feet high on each, a large common pulley or ſhip's block was faſtened, by a ſhort length of rope; through theſe blocks a ſtrong rope was run, whoſe ends terminated in two ſmaller ones, with rings at their ends, as before mentioned: the length of this rope was ſo adapted, that one end reached to the bottom of a very ſteep run or plane of planks that were laid and fixed on the bank, pointing up to the poſt at top; while the other end was nearly at the top of another ſimilar plane at the other poſt. At a proper place between the two pullies, the whipple-tree of a horſe's harneſs was attached or laſhed on to the rope. The operation was conducted, by a man arriving at the bottom of the plane with his loaded barrow, the wheel ſtanding at the foot of the plane, the end of the rope being at the bottom of the plane, and the horſe ſtanding ſtill near the poſt at its top; the labourer then ſlipped the two rings on to the handles of his barrow, and the horſe being ſet in motion towards the other poſt, the barrow was drawn up the plane, and the man alſo with it, who made uſe of his feet, ſuſtaining himſelf from falling backwards by holding faſt by the barrow handles, which he at the ſame time was enabled to guide; when arrived at the top, and entered upon a plane there of leſs inclination, the horſe had arrived almoſt at the other poſt; and while he was ſtopped, and was turned round ready to return again, by the boy who attended him, the labourer ſlipped the rings off his barrow handles, and wheeled the ſame away upon the upper run; another labourer inſtantly ſlipped theſe rings on to the handles of his empty returning barrow, and the return of the horſe let him and his barrow down the plane again, the handles going firſt, and the man holding them as before, but with his back to the barrow; while the other ends of the rope were drawing another labourer and his loaded barrow up the other plane as before. The ſimplicity, diſpatch, and perfect operation of this contrivance, do great credit to its inventor. In very conſiderable works, it will be attended with the greateſt diſpatch, as well as ultimate ſaving of expence, to uſe trams and temporary iron rail-ways; and if the height and quantity of ſtuff to be delivered at any one place be very conſiderable, inclined planes, with ſteam-engines of ſmall dimenſions, (ſuch as are now every day manufactured and improved) ſhould alſo be erected, to draw up the trams, as at the *London Docks* above mentioned. It is evident, that the ſimple and ſtraight courſe for the horſe, attached to the middle of a rope as above, may often be ſubſtituted for the expenſive turn-beams above mentioned, particularly where diſpatch in ſetting the apparatus to work is an object.

Mr. *Ralph Dodd* appears to have contrived a machine to be worked by men, by the means of levers, for excavating canals, which was tried in the year 1794, in the deep cutting at Dawley near Hayes on the *Grand Junction* canal. Mr. *Carne*'s machine for the ſame purpoſe, but worked by a horſe at length, appears to have been uſed in 1794, in the deep-cutting near Coſton Hacket, on the *Worceſter and Birmingham* canal. In the *Monthly Magazine*, vol. ii. p. 594, we have the following account of the operation of *E. Haſkew's* patent excavator: "This machine takes the ſoil from the bottom of the canal, at 40 feet deep, with equal facility as at ſix feet from the ſurface! One of them is at work upon the *Glouceſter and Berkely* canal. By the aſſiſtance of two men only, it removes 1400 loaded barrows from the bottom of the canal, to the diſtance of 40 feet, in 12 hours; and is ſo contrived, as to take up the loaded barrows, leave them at top, bring down the empty ones in regular rotation, and leave them at the bottom. It can be moved along the canal to the diſtance of 26 yards in 10 minutes, by the two men that work it."

In October 1793, Mr. *Joſeph Sparrow* took out a patent for a machine, conſiſting of a box, with its bottom opening on hinges, ſuſpended by a ſort of univerſal gib or crane, the whole moving upon wheels; which he ſtrongly recommends for elevating and diſcharging the ſoil dug out of the canal. See *Repertory*, vol. v. p. 77.

Among the moſt conſiderable deep-cuttings, are thoſe at Aſhton on the *Lancaſter*, Tring on the *Grand Junction*, Coſton Hacket on *Worceſter and Birmingham*, Burbage on the *Kennet and Avon*, Little-borough on the *Rochdale*, Smethwick on the old *Birmingham*, &c.

The *conſtruction of Locks* is ſo important a part of canal-making, and they are ſo very eſſential to the ſyſtem itſelf, that we ſhall give ſome brief particulars of their hiſtory. Mr. *William Chapman*, in his "Obſervations on the various Syſtems of Canal Navigation," has devoted his 7th chapter to an account of the internal navigations of China, compiled from ſir George Staunton's and other authentic accounts. He obſerves, that our pound-locks are unknown in China, (although explained to them by the French miſſionaries in 1685); and it appears from his account, page 76, that their grand or principal canal is, in fact, only a river or ſtream navigation, although greatly diverted by art from its ancient courſe in ſome parts; the current of the water being ſlow, and prevented from running off too rapidly by its deſcent being occaſionally checked by flood-gates, conſiſting of two abutments of ſtone, one projecting from each bank, and leaving a ſpace in the middle juſt wide enough to admit a paſſage for the largeſt veſſels employed upon the canal; and to prevent unneceſſary waſte of water through the flood-gates, the paſſages are occaſionally cloſed by planks let down tranſverſely and ſeparately one above another, their ends reſting in a vertical groove in each abutment; and he obſerves, at page 89, that it was probably between the years of the Chriſtian æra 605 and 618, that theſe were introduced. At page 87, he ſays: "The Chineſe method of overcoming aſcents appears to be long ſubſequent to the attempts of the Egyptians, under the ſucceſſors of Alexander, who, according to Monſ. Huet, biſhop of Avranches, had the art of conſtructing ſluices, or locks of one ſet of gates, ſo as to ſtop the impetuoſity of the current, and be occaſionally opened. Though termed gates, the openings were moſt probably cloſed with beams of timber, let down in grooves; as gates of large width and depth could not be opened without difficulty, even againſt a ſmall difference of level. There are, however, ſuch ſluices with gates upon ſeveral of the running canals on the verge of the *Shannon*. They were erected about the middle of this century, (1750) and are of difficult uſe, becauſe of the force requiſite to open them. Theſe running canals are on the Chineſe principle, and nothing more than new channels for a portion of the river; which, when it is low, are ſtopped as in China, to retain a head of water ſufficient to paſs the boat." And upon, and cauſe the gate to open and ſhut eaſily: the height of the roller above mentioned is made adjuſtable by a ſcrew, ſo that the gate can at all times be kept from dragging on the ſheeting: and inſtead of handles to open ſuch gates, ropes and chains, and capſtans, erected on the banks for the purpoſe, are uſed to open and ſhut them. The upper gates are hung and conſtructed nearly like the lower ones, except that they have no paddle-holes in them, and are uſually boarded no higher than the level of the paddle-weirs behind them, in order to aſſiſt as weirs in carrying off a ſuperfluity of water; but theſe are often attended with bad conſequences, the fall of the water wearing, and in time damaging the breaſt of the lock; and in floods, the ſtream or ſplaſhing of the water may damage goods in, or even endanger the ſinking of, heavy laden boats, in the lock; the ſame may alſo happen with deeply laden boats when the paddles are drawn in aſcending, if the paddle-holes do not enter the chamber of the lock at ſome diſtance below the ſurface of the water, and in a proper direction: on the *Monmouthſhire* canal the paddle-holes are both united, and diſcharge themſelves through the breaſt of the lock into the chamber: a practice that ſeems by no means worthy of imitation. The upper paddles, or thoſe behind the upper gates, are drawn by a rack and pinion, *k*, *fig.* 38, by means of a winch-handle, (which each bargeman and lock-keeper carries with him) in the ſame manner as thoſe in the lower gates, which we have deſcribed above. Guard-rails or curving pieces of timber, *f*, *fig.* 36, ought to be ſtrongly bolted on to piles driven for that purpoſe in the front of the wing-walls juſt above the ſurface of the water, to guide the boats into and out of the locks, without ſtriking the walls; which is far preferable to the huge ſtones let into the wing-walls in ſome places, called bumping ſtones, and calculated rather to break and deſtroy the barges, than protect the walls. It will be neceſſary alſo to provide a ſtrong piece of wood formed to the curve of the breaſt-wall of the lock, *b*, *fig.* 37, before which it ſhould be ſuſpended a few inches above the water when the lock is empty, by means of two or three chains; theſe are called bumping pieces, and are intended to receive the ſtem of the boat, and prevent it ſtriking the wall when the ſame is not ſtrapped or ſtopped in proper time; a practice, however, for which the bye-laws or clauſes in the act ſhould provide adequate fines or puniſhments: and ſtrapping poſts ſhould be ſet firmly into the ground in the proper places for the bargemen to wind their rope, or ſtrap as they call it, and by eaſing it out by degrees, to ſtop the velocity of the boat before it arrives at the gates or breaſt of the lock that it is entering. The gates ſhould alſo be furniſhed with two or three ſtrong upright planks on the lower ſide, *g g*, *fig.* 39, to receive occaſional blows from the noſes or ſtems of the boats, and prevent the planks of the gates being broken or ſtarted thereby. There is room for the ſkill of the engineer to be exerciſed, in forming the lock-ſills and gates to that particular angle which will render them ſtronger for the ſame width and depth of lock, than they would be if they met more acutely, or were ſhorter and met more obtuſely. In very large and wide locks, the gates ſhould not be ſtraight or plane, but a little curving to give them greater ſtrength. On narrow canals, it may not be neceſſary to make double or angle gates, but one gate ſhutting ſquare acroſs the lock may be ſtrong enough to anſwer every purpoſe, and be opened more readily than two gates on the oppoſite banks can be; the upper gates in particular, on account of the comparative ſhallowneſs of the water there, may be ſingle, while the lower gates, if the fall is conſiderable, may be double. In ſetting out canals, where the fall of the ground is very gradual and eaſy, it may be neceſſary to avoid long lengths of deep-cutting below, and of embanking above, or making the line very crooked, to make ſhallow locks, if water is plenty; and under the ſame circumſtances only, will it be allowable to make 10, 12, or more feet locks in particular places, however well the ground may ſuit the ſame; many of theſe double locks were at firſt erected, as on the old *Birmingham* canal, and the *Calder and Hebble* navigation, where about 1783 ſingle locks were obliged to be ſubſtituted, to avoid the waſte of water, before pointed out.

We have not yet noticed an inconvenience and waſte of water, which attend the placing of locks nearer to each other than about 100 yards, or having baſons between them, equal in area to about that length of the canal, as was done at Salter Hebble in 1783 in the alteration above mentioned; without which precaution, a boat in deſcending lets down more water than the pond below will hold, without raiſing its ſurface ſo as to loſe a good deal over the lock-weirs, and ſtill worſe happens in aſcending, for the ſhort pens are ſo much lowered by filling the lock below, that laden boats are unable to proceed for want of water, until a ſupply is let down to waſte, through the upper lock, to help them forwards. As many locks as can conveniently be brought near to each other, on the principles above, and before explained, ſhould be contrived, if it can be done, to be in ſight of each other, and of a length of canal each way; and the lock-keeper's houſe ſhould be ſo placed, that he can when at home at his meals, or otherwiſe, in bad weather, ſee barges approaching the locks, in time to meet them before they enter the locks. Mr. *Fulton* who wrote in 1796 ſays, that the coſt of locks for 25 ton boats, was about 70l. per foot riſe, and for 40 ton boats, about 100l. per foot riſe; this may ſerve to give ſome general idea of the coſt of locks at that time; but we would obſerve, that the decreaſe of the value of money, and the exceptions to all general rules on theſe ſubjects are ſo many, no dependence ought to be placed on ſuch modes of eſtimating. If ſufficient water-way is given in the paddles, and there is aſſiſtance enough to draw both the paddles, and open and ſhut the gates at the ſame inſtants, a boat may paſs each lock of the uſual conſtruction and riſe, in three minutes time, but in general, 5½ minutes will be nearer to the average time loſt at each lock, as obſerved by Mr. *Bevan* on the *Grand Junction* canal. Theorems for the time of filling a lock of given dimenſions, and with given paddles and fall of water, ſhould be found and compared with many experiments on the locks under the care of our reſident engineers. (See *Nicholſon's Journal* 8vo. N° 9, vol. iii. p. 30.) It ſhould be conſidered, that a boat going up lets down or conſumes twice the weight thereof (boat and cargo included) in water, more than in going down through each lock; for the boat on entering the empty lock, expels as much water into the lower reach as its own draft of water, which is made good out of the upper pound when the boat enters the ſame; while a deſcending boat expels its own flotation bulk of water from the full lock into the upper pound, where it is retained on the ſhutting of the upper gates; the mean of a paſſage each way will be a lock-full for each boat, unleſs they go always loaded one way, and empty the other. Mr. *Fulton* ſays, that the conſumption of 25 ton boats through eight feet locks, will in general be about 163 tons of water in aſcending, and 103 tons in deſcending; and Mr. *Chapman* informs us, that boats paſſing and repaſſing a ſummit, laden one way, and returning empty, will require nearly 13 times the weight of their lading of water for their lockage, out of the ſummit pound. Seven hundred tons of lading per day are as much as paſs or repaſs upon any one of our canals, according to Mr. *Fulton.*

We cannot with propriety quit the ſubject of conſtructing locks, without mentioning *coffer-dams*, which are a double range of piles drove very cloſe to each other in a circular form round the mouth of any canal or dock, that is to have a lock built, repaired, or altered, connecting with the ſea, a river, or any exiſting navigation that cannot be emptied of its water; the interval between the piles being filled with earth, the water in the ſpace between the coffer-dam and the intended works is then pumped out for the works to proceed; the many and fatal accidents to which theſe are liable, eſpecially when the works are nearly completed, and the earth is excavating from the bottoms to open the paſſage freely to the lock or works, require all the precautions, ſkill, and attention of the moſt able engineers, eſpecially when the riſe and fall of the tides or waves of the ocean, preſent unequal action on the piles and dam.

The *ſaving of water in the uſe of locks* is a conſideration of ſo much importance in moſt of the inſtances which occur, that it is neceſſary we ſhould mention ſeveral of the expedients which have at different times been propoſed, or practiſed for that purpoſe. Some of the moſt obvious of theſe are, a minute attention to the fitting of the gates and paddles, conſtructing every part of them of the moſt ſeaſoned and durable materials, with the utmoſt precautions againſt partial wear or liability to accidents, by which the gates or paddles would leak and waſte the water; and ſhould ſuch leaks happen, the eſtabliſhment for working the canal ought to be ſuch, as to detect the ſame immediately, and apply the proper repair or amendments without delay. It is of great importance, to adapt the plan or ſurface of the water in the lock, to the ſize of the boat or boats that are to be uſed, leaving as little water uncovered in the chamber of a lock as poſſible, and for this purpoſe, where water is ſcarce, it will be neceſſary to enforce the regulations, that the act ought to contain for the length, width, and form of the boats that are to be uſed; and on canals for large and ſmall boats, to ſee that two or more of the ſmaller boats are ſo contrived as to lie cloſe together in the lock, and occupy the whole ſpace thereof as one of the large boats would do: leſs than this number of ſmall boats muſt not, when water is ſcarce, be allowed to paſs, or without paying ſuch increaſed tonnage or lock dues, as will act like a prohibition.

The *waiting for turns*, particularly by empty or lightly laden boats, ought alſo to be provided for, and it may be neceſſary on ſome occaſions to enforce the ſame; viz. to ſuffer no boat to paſs down, until there is another arrived below, and ready to aſcend as the lock is filled; or any boat to aſcend, till another is ready above to deſcend with the ſame lock-full of water. Where ſmall or ſhort boats are in pretty general uſe upon a canal, as on the *Shrewſbury*, it may be right to adopt the practice which Mr. *Thomas Telford* has deſcribed, who ſays, "the locks are ſo formed as to admit of either one, three, or four boats paſſing at a time, without the loſs of any more water than what is juſt neceſſary to regulate the aſcent or deſcent of the boat or boats that are then in the locks. This is accompliſhed by having gates that are drawn up and let down perpendicularly inſtead of being worked horizontally; and each lock has three gates, one of which divides the body of the lock, ſo as to admit of one, three, or four boats at a time." See *Plymley's* Report before quoted, page 299.

A very ſenſible writer, who has given a full account of the *Grand Junction* canal, in the *Agricultural Magazine* for 1803, vol. viii., under the ſignature of a conſtant reader, ſuggeſts at page 204, the propriety of an additional ſet of narrow locks on each ſide of the ſummit which is in want of water, for the uſe of the narrow boats, to which they ſhould be exactly fitted; as alſo, to avoid the expence of lifting or pumping water, that can be collected in reſervoirs or feeders at ſome diſtance below the ſummit level, by uſing ſhallow locks of only three or four feet riſe each, between the ſummits and the points where ſuch waters can be taken in without lifting. The pumping of water from a lower level to ſupply the waſte of lockage, by means of ſteam engines, has been practiſed with ſucceſs on the old *Birmingham*, the *Barnſley*, and ſeveral other canals; the *Croydon* was to be conſtructed with a dependence on this mode of ſupply, as appears by its act; and on the *Grand Junction*, engines have lately been erected near Tring and near Braunſton, for raiſing water to the ſummit-levels. A very conſiderable power is loſt in the deſcent of the water through the paddle-holes, to fill the lower part of a lock, and again through the gate paddles in emptying the upper part of the lock; we have often thought that it might be practicable to apply this power for returning a certain quantity of water into the upper pound, either by making the deſcending ſtream act on a wheel, or on vanes like thoſe of a ſmoak-jack, or by means of hydroſtatic preſſure, or momentum machines. See *Monthly Magazine*, vol. vi. page 124.

*Side-ponds* are an expedient for retaining part of the water, from the upper part of a lock when it is to be emptied, and to uſe the ſame towards filling the lock again for the next boat: they are ſaid to have been invented by M. *Dubie*, and one with 3 diviſions was tried in a lock of 20 feet fall, on the canal of *Ypres*, near 100 years ago; they are deſcribed by M. *Belidor*. On the 5th July, 1791, Mr. *James Playfair* took out a patent for this mode of ſaving water in uſing locks. See *Repertory*, vol. iii. 303. And in the ſame work, vol. i. p. 377, Mr. *W. Pitt* has deſcribed three ſide-ponds, in form of ſectors of a circle. We read that in April laſt, (1805) an experiment was made on the *Grand Junction* canal, and two of theſe ſide-ponds, with earthen banks like a canal, and each about the ſame ſize as the lock, were tried near Berkhamſtead; into one of them, whoſe bottom coincided with about half the height or altitude of the lock, the upper quarter of the water of the lock, for a deſcending boat, was drawn, and it was there retained by a cloſe ſhuttle; the ſhuttle of the other ſide-pond, whoſe bottom was about level with one-fourth of the height of the lock, was then opened, and about another quarter of the water in the lock flowed into it, and was there retained by the ſhuttle; the remainder being emptied by the gate-ſhuttles into the lower canal; and the boat having paſſed out, and another aſcending one taken its place in the lock, the ſide-pond that had laſt been filled was emptied into the lock, and then that alſo which had been firſt filled; theſe together filled half the lock, before the upper paddles were drawn to fill up the remainder, the ſhuttles of the ſide-ponds being firſt ſhut down; by this means, two boats were paſſed, by letting down only half a lock-full of water into the lower pound; and the lock remained full, ready for another deſcending boat, as before. The time taken up by the above operations was about nine minutes for each boat that paſſed, or 3½ minutes more than if the ſide-ponds had not been uſed. We underſtand that ſide-ponds are becoming common on different canals; their conſtruction offers a very curious exercise for the abilities and ſkill of the engineer, ſo to apportion the number, ſize, and height of the ponds, that, conſidering,

dering the expence of conſtruction, loſs of time in paſſing, and the ſaving of water that is effected, the reſult may be the moſt advantageous.

It appears, that Mr. *Michael Logan* took out a patent in 1804, for raiſing or forcing water into a lock; alſo, that in January 1791, Mr. *Joſeph Brooks* obtained a patent, for a method of drawing up the falſe or moveable bottom of a deep ſide-pond or large well near a lock, and by that means filling the lock with water, until a barge had paſſed up, or another was ready in the lock to deſcend, when the falſe bottom being again let down, the water retreated by the ſame connecting culvert that had brought it into the lock, it was again emptied, and the boat able to proceed on the lower canal, without having waſted or let down any water. See *Repertory*, vol. vii. p. 361.

Mr. *Lawſon Huddleſton* has communicated, through the medium of *Nicholſon's Journal*, 8vo. vol. iv. p. 236, a method of raiſing the water in a lock, from a deep ſide-pond or well as above, by means of a ſolid or heavy plunger that can be let down into the well, by means of machinery that ſuſpends it, when the water is to be raiſed, and drawn up when it is to be allowed to ſink again; the plunger being balanced in all its different degrees of immerſion by a counter weight acting on a ſnail or ſpiral curve.

Mr. *Robert Salmon* has invented a different mode of accompliſhing the ſame thing; his plunger being hollow, and as buoyant as poſſible; and for forcing the ſame down into his ciſtern or ſide-pond, when the lock is to be filled with water, he has contrived a very curious apparatus; it conſiſts of a very heavy carriage on four low wheels, or heavy rollers of metal, connected together by a frame to anſwer the ſame purpoſe. Two frames or planes are prepared, that turn on fixed centres, as a door does on its hinges, but horizontally inſtead of vertically; the other two ends of theſe planes reſt on the two ends of the plunger, by means of uprights therefrom and moveable joints; upon theſe planes the carriage rolls, in ſuch a manner, that when it is drawn forwards, by means of a rope or other machinery, the weight advances upon the plunger, and the planes being at liberty to turn on their joints, it ſinks the plunger by degrees, until at length the four wheels reſt exactly over the joints at the ends of the plunger, exerting the whole weight of the wheels and carriage, to keep it down and elevate the water in the lock; on the carriage being withdrawn, the weight on the plunger leſſens, and it riſes, until at length the four wheels reſt juſt over the hinges or fixed joints, and no part of the weight of the carriage or wheels is then exerted upon, or to counteract the buoyancy of the plunger, and the water retreats from the lock into the ſpace under the plunger. That this carriage, which muſt be extremely heavy for large locks, may not be ſubject to run forwards or backwards on the planes; Mr. *Salmon* has contrived one of them with a peculiar curvature or bend, ſo that the tendency of the carriage is as great to advance as to retreat, in every part; and a conſtant and ſmall weight, hung on the end of a line over a pulley, in the model, will cauſe it to move either way, with a regular and ſteady motion. During the laſt ſeſſion of the *Society of Arts*, in the *Adelphi*, Mr. *Salmon* preſented a model and deſcription of his invention, for which he was honoured with a premium; the model is lodged in the Society's collection, for public inſpection, and a particular deſcription of the ſame is expected to appear in their next, or 23d volume of *Tranſactions*. Mr. *Salmon* has hit upon a method of mechanically conſtructing the *curve* above-mentioned for one of the planes, which is found to approach very nearly to the arc of a circle. A mathematical friend of Mr. *Salmon*, who was ſhewn the model in an early ſtage of his experiments thereon, has propoſed as the 84th queſtion in *Leybourn's Mathematical Repoſitory*, the determination of the nature of the curve in a particular application of Mr. *Salmon*'s principle; we are ſorry, however, to ſee this queſtion ſtill unanſwered by the ingenious correſpondents of that very uſeful and learned work; becauſe this curve promiſes to be applicable on ſeveral occaſions in the conſtruction of hydraulic machines. We have been treating of various contrivances for ſaving water in the uſe of locks of the common conſtruction; and we ſhall now proceed to mention ſeveral ſubſtitutes for locks in overcoming aſcents on a canal or river, but in which the boat continues floating in water; before we proceed to inclined planes, or other ſchemes, in which the boat is to be drawn or ſuſpended out of the water, or the goods to be removed by cranes, &c. to other boats.

*Subſtitutes for locks*, have been called for in ſome ſituations by the actual ſcarcity of water, in others by the previous and neceſſary appropriation of the whole of the ſtreams to mills or the practice of irrigation, and not in a few caſes by the jealouſy and oppoſition of mill, park, and land owners; the intemperate zeal alſo of ſome projectors may have operated, who do not heſitate to prognoſticate the annihilation of lock-canals, by "improved ſcience; in like manner as improvement in machinery renders the old apparatus uſeleſs." See *R. Fulton's Treatiſe*, page 28 and 110, *&c.*: alſo, *W. Chapman's Obſervations thereon*, page 2, &c. Several canals have, like the *Haſlingden*, been reſtricted from erecting locks in particular places, without the mill-owners' conſent; it is therefore no matter of ſurpriſe, that various ſchemes have been propoſed to obviate the neceſſity of common locks. On rivers where the boats are hauled up againſt the ſtream, it is not unuſual to lighten a boat by ſhifting part of its cargo into other boats, called lightening boats, ſo that their diminiſhed draft of water may enable them to be dragged over any particular rapid; and in more extreme caſes, the whole of the lading may be taken out, and be conveyed by land to meet the boat again after it has been dragged empty over the rapid. Rapids may themſelves often be made navigable by jetties, or contraction of the width of the ſtream in ſuch places, and if the fall is rendered very conſiderable thereby, capſtans or machinery may be erected for the hauling up or eaſing down of boats; theſe methods have doubtleſs been in uſe from the earlieſt periods; and we read of great numbers of men in China being employed with ropes to haul boats up their artificial rapids or falls. The methods of uſing ſtop-planks occaſionally to cauſe an artificial flood in Egypt, China, Flanders, and Ireland, as before-mentioned (when ſpeaking of the invention of locks), are alſo very ancient, and ſuch are ſtill in uſe upon ſeveral of our rivers; on the *Ivel* river below Biggleſwade, we think we remember ſeeing upright narrow planks uſed againſt a moveable beam at top of the water, and a fixed ſill at the bottom of the ſame, for penning the water and producing a fluſh or flaſh of water, when the planks are removed and a boat is to paſs. On moſt of our old river navigations there are gates erected to pen the water, and the ſame are drawn up to occaſion a ſudden flaſh while a boat is to paſs. At the entrance of the Worſley mine on the Duke of *Bridgewater*'s canal, we remember a large door that was drawn up for our boat to paſs under it into the tunnel, and then let down to pen the water therein three or four inches higher than it ſtood in the canal. The difficulty of opening large gates, to produce a fluſh of water or to let a boat paſs has been before noticed ; and in the *Memoires de l'Acad. des Sciences* for 1707, we find the deſcription by *M. de la Hire* of gates calculated to obviate this inconvenience in part, by having a large pair of doors in the gates opening the contrary way, or with the ſtream, which on the drawing of a pin can be let to open by the preſſure of the water ; after which the great gates can be opened with eaſe, and when open, the doors can as readily be ſhut again and pinned, owing to their ſtanding in the direction of the ſtream ; and the gates then are ready to be ſhut again as ſoon as the head of water is run off, or the boat has paſſed. It appears, that in extending the navigation of the *Seine* river in France, gates were introduced, which the Duke of *Rouanez* had invented, and which are deſcribed in the *Memoires de l'Acad. des Sciences* for 1669, conſiſting of two upright gates, rather wider than half, and as deep as the channel of the ſtream or river, bent into the arc of a circle of about 48 feet radius; to each of theſe gates ſeveral long beams of wood were fixed, meeting in or near the centre of the circle, of which the gates formed a part ; and here being firmly united, they abutted againſt a ſolid pier of ſtone, or worked on a centre-pin fixed in a ſtrong pile, drove very firmly into the earth by the ſide of the channel, at 48 feet below the place where the gates were intended. A notch was formed in the bank of the channel on each ſide, in form of ſectors of circles, ſufficiently large to contain the two gates and their beams or centering as above. By this conſtruction, the whole of the preſſure of the gates when ſhut and the water penned by them, was brought to act on the two upright pins or centres ; and a very moderate force applied to the head of each gate would draw them apart and into the ſector-like receſſes prepared for them, leaving the channel or courſe of the ſtream perfectly free of any obſtacle, to check either the current or a boat in paſſing through. By a ſmall adjuſtment of the places of the centres, gates of this kind may at all times be made to fit cloſe to each other in the centre of the channel, on its bottom, and alſo to the ſide walls of the channel above them, and yet on being moved a ſmall ſpace from each other they may clear thoſe walls and be free to move into the receſs, in the bottom of which there may be ſmall rollers to carry the gates with leſs friction, or rollers under the gates may be uſed for the ſame purpoſe. See *Jacob Leupold's Theatrum Machinarum*, folio, publiſhed in 1726 at Leipſig.

Dr. *James Anderſon*, of Edinburgh, has contrived, and publiſhed in 1794, in his *General View of the Agriculture, &c. of the County of Aberdeen*, a method of elevating or depreſſing ſmall boats, floating in a coffer or large tight open caſe full of water, that can at will be made to coincide and connect at one of its ends with either the upper or lower canal ; into or from which the boats may paſs without the loſs of more water than is neceſſary to fill the narrow ſpace between a draw-gate at the end of each canal and at the ends of the coffer, when the ſame is preſſed and retained cloſe to the end of the canal, and a ſmall additional quantity to reſtore the equilibrium and give motion to the coffers, of which there are two exactly of ſimilar dimenſions ſuſpended and connected together by ſtrong chains. *Mr. Chapman's* conciſe deſcription of this invention is ſo much to our purpoſe, that we beg to uſe his words, who ſays, "the doctor there obſerves, that, for all the purpoſes of commerce, no more width of boat is requiſite than four feet, or more than two or three feet depth ; and that the length might be indefinite, ſo as not to be inconvenient for aſcending and deſcending between any two levels of canal, which he propoſes to be done in the following manner, viz. that the lower level be run up to nearly under the end of the upper, and terminate by an upright end and two ſide walls of maſonry, to the full height of the fall, with a pier in the middle dividing the paſſage between the two ſide walls into two openings of rather greater width than the boat ; the two ends of this pier are to be elevated ſo as to ſuſtain the axis of a wheel, of a diameter equal to the width of the pier, and half of each opening. A chain paſſing over the wheel ſuſpends from each end a rectangular caſe, ſo hung, that when one ſhall be at the bottom ready for a boat to float into, the other ſhall be at the top, and cloſe preſſed to the wall or frame at the end of the canal, ſo as to prevent the eſcape of water ; then, by opening a ſtop-gate at the end of either canal, and another at the correſponding end of the caſe, it is obvious that the boat may float in or out. The lower boat and caſe (or caſe with water only) are then in a kind of lock juſt containing the caſe, and of ſufficient depth to permit it to deſcend to the level of the lower canal. From this lock there is a conduit to keep the water down below the canal bottom. Theſe are the outlines of the invention, which, where the connection between the two levels is a precipice, or ſo ſteep as to require only a ſhort tunnel to the well or pit, up or down which the boats are to move, may, on receiving ſuch improvements as it is capable of, be eaſily carried into effect for ſmall boats, for which the author alone propoſes it. It is obvious that under other circumſtances, as to ſituation, the expences of high embankments above, of deep ſinking below, and of bringing up the conduit to lay dry the lower locks, muſt more than counterbalance any advantage than can be derived from it." Where the fall is conſiderable, the doctor has propoſed a balance chain, of the ſame weight per foot as the ſuſpending one, to be hung from each coffer or caſe. See *Repertory*, vol. ii. p. 21.

On the 24th December, 1798, Mr. *James Fuſſell* took out a patent, (ſee *Repertory*, vol. xi. p. 7.) for a method differing in principle from that of *Dr. Anderſon* above deſcribed, only in having an axle and *two* wheels thereon, at a diſtance from each other on the middle pier, and under his coffers or receptacles, ſimilar axles with a pair of wheels, and inſtead of his coffers or receptacles being ſuſpended from the two ends of a chain paſſing *over* the wheel, as in *Dr. Anderſon's* method, *Mr. Fuſſell's* two chains are fixed to the tops of the ſide walls, paſſing *under* the wheels of his receptacles, and over the wheels and axle on the middle pier. He alſo deſcribes rollers or guides by the ſides of his lock-pits to ſteady the receptacles, and a toothed wheel on the middle ſhaft or axle connected with a fly or brake wheel to regulate the motion of the chains and receptacles ; he alſo propoſes the gates or hatches at the end of his receptacles, to be balanced by counterweights, and to draw down into a cavity prepared for the purpoſe, when a boat is to be paſſed in or out, inſtead of drawing up. And if the fall be very conſiderable, he ſuggeſts the propriety of a ſhort tunnel or arch to conduct the lower canal into the lock-pit, inſtead of an open notch or perpendicular-walled cut in the hill for the lower canal. It appears that this balance-lock of *Mr. Fuſſell's* was put in practice, or at leaſt tried, on the *Dorſet and Somerſet* canal, near Froome, on the 6th of September, and 13th of October 1800, on a 21 feet fall, and with boats of ten tons burthen ; delays in completing the above canal, and forming a communication, prevented this lock from being made uſe of for a long time afterwards ; but we believe that the note of a late writer on the above experiments, ſtating that a ſubſcription was ſet on foot in 1802, to raiſe money to make a lock in this very place, originated entirely in miſtake.

On the 18th of March, 1794, Meſſrs. *Rowland* and *Pick-*

the axis or barrel for the rope, to give motion to the ropes and cradles with their contents, when a ſufficient quantity of water had been let into the upper cheſt by a valve and pipe contrived for the purpoſe, or out of either of the cheſts by means of a ſtring attached to their valves, till an equilibrium of the two cheſts, cradles, and boats upon them were obtained. By this apparatus it was propoſed, that in general one boat ſhould be aſcending upon one of the planes while another deſcended on the other; but the caiſſons were large enough to admit of ſufficient water from the upper or lower level being taken into one of the cheſts, to balance a loaded boat on the other. The capſtan worked by men was propoſed to be uſed, for dragging boats out of the upper canal over the upper plane and platform on to the cradle in order to deſcend. Walking-wheels, to be worked by men, were alſo propoſed inſtead of water-wheels, where the water was very ſcarce in the upper canal. The canals abovementioned were never carried into execution, although an act of parliament were obtained for the former, nor have we heard of any of Mr. *Leach*'s planes being brought into actual uſe.

Mr. *William Reynolds*, of Ketley, in Shropſhire, was the firſt who contrived and executed an inclined plane (which was completed in 1788) for the paſſage of boats and their cargoes, which was found fully to anſwer, and continued in practical uſe. Mr. *Thomas Telford* has thus deſcribed the ſame, in *Plymley*'s Agricultural Report of Shropſhire, p. 291. Mr. Reynolds "having occaſion to improve the mode of conveying iron-ſtone and coals from the neighbourhood of the Oaken-gates to the iron-works at Ketley, theſe materials lying generally at the diſtance of about a mile and a half from the iron-works, and at 73 feet above their level, he made a navigable canal," called the *Ketley* canal, "and inſtead of deſcending in the uſual way, by lock, continued to bring the canal forward to an abrupt part of the bank, the ſkirts of which terminated on a level with the iron-works. At the top of this bank he built a ſmall lock, and from the bottom of the lock, and down the face of the bank, he conſtructed an *inclined plane*, with a double iron rail-way. He then erected an upright frame of timber, in which, acroſs the lock, was fixed a large wooden barrel; round this barrel a rope was paſſed, and was fixed to a moveable frame; this laſt frame was formed of a ſize ſufficient to receive a canal boat;" theſe boats were 20 feet in length, 6 feet 4 inches wide, 3 feet 10 inches deep, and each carrying 8 tons; "and the bottom upon which the boat reſted was preſerved in nearly an horizontal poſition, by having two large wheels before and two ſmall ones behind, varying as much in the diameters as the inclined plane varied from an horizontal plane. This frame was placed in the lock, the loaded boat was alſo brought from the upper canal into the lock, the lock-gates were ſhut, and on the water being drawn from the lock into a ſide-pond, the boat ſettled upon the horizontal wooden frame, and as the bottom of the lock was formed with nearly the ſame declivity as the inclined plane, upon the lower gates being opened, the frame with the boat paſſed down the iron rail-way on the inclined plane into the lower canal, which had been formed on a level with the Ketley iron-works, being a fall of 73 feet. Very little water was required to perform this operation, becauſe the lock was formed of no greater depth than the upper canal, except the addition of ſuch a declivity as was ſufficient for the loaded boat to move out of the lock; and in dry ſeaſons, by the aſſiſtance of a ſmall ſteam engine, the whole of the water drawn off from the lock was returned into the upper canal, by means of a ſhort pump. A double rail-way having been laid upon the inclined plane, the loaded boat in paſſing down brought up another boat, containing a load nearly equal to one-third part of that which paſſed down. The velocities of the boats were regulated by a brake acting upon a large wheel, placed upon the axis, on which the ropes connected with the carriage were coiled." It appears that this plane has an inclination of about 22°, except near the extremities, where it diminiſhes to about $11\frac{1}{2}$°; and that about 400 tons of coals uſually deſcend thereon daily. In 1789 a copper medal, or halfpenny, having a repreſentation of this plane on one ſide, and of the caſt-iron bridge at Coalbrook-dale on the other, was ſtruck, and iſſued by the Coalbrook-dale company. Since the practicability of inclined planes has been eſtabliſhed, by the ſucceſs of the Ketley plane, but few acts have been paſſed for new canals, without a clauſe authorizing the company to erect inclined planes, inſtead of locks, if they ſhould be found moſt adviſable. Before proceeding to mention the inclined planes of different conſtructions, which have been ſince made or propoſed, we ſhall notice the under-ground plane at Walkden Moor, which was completed in October 1797, upon *Bridgewater*'s canal, it being ſo ſimilar to the Ketley plane above deſcribed.

The *Duke of Bridgewater*, in the year 1800, cauſed an account to be preſented to the Society of Arts, in the Adelphi, London, of the inclined plane which he had erected and brought into uſe, under the direction of his agent, Mr. *Benjamin Sothern*, between two different levels of his tunnels or ſubterraneous canals from Worſley near Mancheſter; for which the Society voted his grace their gold medal, and publiſhed plans and ſections, and an account thereof, in their 18th volume of *Tranſactions;* to which we refer, only mentioning, that this plane, which is $35\frac{1}{2}$ yards high, and 151 yards long, through an inclining tunnel hewn in the ſolid rock, at near 60 yards below the ſurface of the ground, differs from the Ketley plane, in having, upon about 57 yards of the lower end of the plane, a ſingle rail-way only, to or from which the two rail-ways above join by eaſy curves, to proceed up to the locks by one rail-way, or down by the other. A winch and pinion are provided, to be occaſionally worked by two men, into cogs in the large brake wheel, for ſetting the boats in motion. Rollers are placed between the iron rails, for the ſlack part of the great ropes to run upon, and for further preventing the wear of theſe ropes, they are lapped round with a ſmall cord. About 12 tons of coals are let down in each boat, and a boat and cradle on which it runs, weigh about 9 tons more. About 16 minutes is conſumed in paſſing a pair of boats: the boat-cradles are 30 feet long and $7\frac{1}{3}$ feet wide, moving on 4 iron rollers. A ſmall bell gives notice from the bottom to the top of the plane, when the boats are placed on the cradles, and the machine ready to work. The water of the locks is let down by a paddle, through a perpendicular ſhaft, to the middle canal, and acts as a water-bellows to force freſh air down into the extenſive tunnels and works that are on the lower level. The upper gates of the locks turn in hollow grooves like a common lock, but the lower gates draw up in grooves, by means of windlaſſes, to let the boats paſs out or in when the water is let off.

Mr. *William Reynolds* has the honour of introducing another ſort of inclined planes, on the *Shropſhire* canal, where there are three planes in uſe of 120, 126, and 207 feet riſes! The act for this canal paſſed in 1788, and it was completed, under the direction of Mr. *Henry Williams*, as reſident engineer, and opened in 1792. Theſe planes are upon the ſame conſtruction as thoſe at Ketley, except that there are no locks at the top of the deſcending planes, but the ſame are continued above the ſurface of the water in the upper canal, and terminate in a croſs beam, from which another plane and rail-way deſcend into the upper canal: this is for avoiding the waſte of water which locks at the top of the planes occaſion. A ſmall ſteam engine is uſed for working the axis of the rope barrel, at ſome diſtance from which, on the upper ſide, there is a large pulley or wheel, fixed at a proper height, for the great rope to paſs over, to draw the boats up or let them down the long deſcending plane; another ſmaller axis and rope barrel are provided, which can, like the larger one, be caſt in or out of the engine-geer at pleaſure; this laſt is uſed for hauling the boats up the ſhort aſcending plane, from the upper canal. The engine can alſo be uſed to draw empty boats occaſionally up the long plane, in caſe ſuch want to paſs, when there are no loaded ones ready to deſcend, and draw them up, as we have before deſcribed. The wheels or rollers under the cradles appear on theſe planes to be equal in diameter, and not of different ſizes, ſo as to bring the two ends of the boat to a level, as on the *Ketley;* they do not, therefore, appear applicable to very ſteep planes or to long boats. On the windmill plane, which is 600 yards in length, and 126 feet riſe, ſix boats have been paſſed down, and ſix taken up within the hour, the ſteam-engine and three men only being employed: the boats here are of the ſame length and breadth as on the *Ketley*, but ſhallower, ſo as to carry but five tons; and ſuch boats are ſaid to be paſſed down theſe planes for three-pence each, and the empty boat taken up gratis. At Wombridge on the *Shrewſbury* canal, Mr. *Thomas Telford* has ſince erected a plane, 223 yards in length, and 75 feet riſe, exactly on the ſame conſtruction as the above, of which an account, with plans and ſections, may be ſeen in *Plymley*'s Report, p. 294.

On the 18th of June, 1793, Mr. *Joſhua Green* took out a patent for the uſe of double inclined planes and rail-ways, on which cradles for the boats are to be uſed, conſiſting of a frame of wood, and the bottom corded by ſtrong ropes acroſs each other like the common bedſteads, that the boat may not be ſtrained; in order to introduce wheels of four feet diameter for the cradle to move upon, a ſtrong frame is to ſurround the cradle, and be firmly bolted to it, but leaving an interval ſufficient for the four or more wheels to move between it and the cradle, by which the axles can be fixed to the wheels, and work in gudgeons at each end, with leſs friction than common wheels or rollers. To his brake-wheel handſpokes are adapted, for men to aſſiſt in ſetting the machine in motion, inſtead of a winch as before deſcribed on *Bridgewater*'s; the ropes are to be capable of adjuſting to the proper length as they ſtretch or contract, by a ſcrew or otherwiſe. A third inclined plane is directed to be made, for the purpoſe of carrying a counter weight or veſſel, whoſe rope is to paſs over another axis with a brake and handſpoke wheel, for hauling the cradles and boats out of the upper level to the ridge or croſs beam, or to eaſe them down into the ſame. He recommends ſpare veſſels laden with water to be in readineſs to paſs up or down the oppoſite plane, as a counterpoiſe to any ſingle loaded boat that may arrive at the plane. Alſo that ſingle planes, and with leſs inclination, may in ſome inſtances be adopted. See *Repertory*, vol. v. p. 11.

*Earl Stanhope*, in the year 1793, in recommending the *Bude and Hatherleigh* canal, propoſed, between the different ponds or water-levels of the intended canal, to have iron rail-roads of gradual and eaſy aſcent, on which boats of two tons were to be uſed, ſuſpended between a pair of wheels of about 6 feet diameter, and to be drawn up or let down the ſame by a horſe, in order to be launched in the upper or lower water-level or canal.

On the 8th of May, 1794, Mr. *Robert Fulton* obtained a patent for the uſe of a double inclined plane, whereon cradles having ciſterns or caiſſons under them, no ways different from Mr. *Leach*'s above deſcribed, except that the boats were in ſome caſes to be taken on to the cradles *ſide-ways* inſtead of length-ways; this was propoſed to be accompliſhed by ſhort inclined planes, on which the boats, upon wheeled carriages, were to be dragged out of the upper and lower canals by means of ropes working on the axles of water-wheels; a brake is to be uſed for regulating the motion of the boats and ciſterns, when brought nearly to an equilibrium by the valves; brace-blocks, or pulleys, to be uſed for ſhortening or lengthening the large ropes when neceſſary. See *Repertory*, vol. vii. p. 222.

Mr. *William Chapman*, at page 85, of his Obſervations, which were written principally in anſwer to Mr. *Fulton*'s treatiſe, ſuggeſts this *ſide-way* motion of boats on inclined planes, as before-mentioned, not knowing, as we apprehend, of Mr. *Fulton*'s patent above-mentioned, becauſe it was not publiſhed till 1797; and it is indeed ſingular, that Mr. *F.* ſhould, in 1795, have written 144 quarto pages on the ſubject of canals, and not once have given a hint of his having taken out a patent in the year before for ſome of the principles therein explained, and ſo highly recommended; nor does his long letter in the *Star* Newſpaper of the 30th of July 1795, announcing this work being in the printer's hands, make the leaſt reference to his patent. The Board of Agriculture muſt, we are confident, have been equally in the dark, in March 1796, or they would not have given Mr. *R.* the opportunity of puffing into notice, a ſubject wherein he was a patentee through their means. We beg here to remark, that our duty, in treating this part of our ſubject, ſeems to require the mention of all the inventions and methods which have come to our knowledge; and though we ſhould have more pleaſure in making known the inventions of thoſe who lay the ſame at once open to the community, yet, as all of theſe will be ſo in a few years, we have not thought it right to exclude or be leſs particular in the mention of, inventions or contrivances ſo circumſtanced: but to give the dates of ſuch patents wherever we could, that their termination (at the end of 14 years) may be known.

Mr. *Robert Fulton*, in his 4to. work, entitled a "Treatiſe on the improvement of Canal Navigation," publiſhed in London in 1796, with many plates, has propoſed the uſe of narrow canals and inclined planes, on which ſmall and ſhallow rectangular boats are to be uſed, having low *wheels*, or rather trucks fixed underneath their bottoms; he propoſes to have on his double inclined planes, an endleſs chain paſſing up the track of one plane and down the other, round or over wheels that are of the proper ſize and fixed in proper places and directions at top and bottom of the planes to ſuit the ſwag or curvature of the leading chain; theſe are made to revolve at pleaſure, with power ſufficient to drag a loaded boat up one of the planes, (by means of a ſhort double chain belonging to the boat which is to be hooked into, and will at the proper time diſcharge itſelf from the leading chain), by means of toothed geer attached to the upper wheel, on which there are ſtubs to prevent the chain from ſlipping; which connect with a water-tub deſcending in a perpendicular ſhaft, diſcharging itſelf at bottom by means of a valve, and returning again to the top, when caſt out of geer, by means of its counter weight, balance-chains, and fly, ready to be again charged with water from the upper canal. The motion of the whole is regulated by a pair of fanners or an expanding fly; a ſmaller axle and cog-wheel are provided, working into the tub-ſhaft geer, when neceſſary to draw the boats up a ſhort plane that deſcends into the upper canal, on to a bridge or curving top which unites the two planes, a ſtop being provided to retain the boat in its proper poſition, while this laſt chain is diſcharged, and the boat-chains are hooked into the leading chains as before mentioned. When a deſcending boat happens ready to draw another up, or a ſingle one requires to be let down, the tub-geer is to be caſt off after the boat has been dragged on to the bridge thereby, and the fanners are to be truſted to for eaſing it down. Mr. *Chapman*, who reviews this ſyſtem, juſtly objects to the ſmallneſs of the boat-wheels, and recommends that larger ones ſhould be uſed in a water-tight caſe or groove in the floor of the boat. Owing to the endleſs chain, Mr. *Fulton* ſays, that during part of the deſcent of a boat, the power thereby acquired may draw another boat out of the upper canal on to the bridge; and a boat may in ſome caſes be kept ready in that ſituation to begin the work; or, he propoſes a common windlaſs tooth and pinion to be uſed for that purpoſe. For protecting delicate goods in his boats, he propoſes a frame above the boat for ſupporting the leading chains; and for transferring light timber that is too long for his boats, he propoſes rafts to be made with a carriage under them, having wheels like thoſe of his boats, by which theſe rafts are to be conveyed on the inclined planes. A totally deſcending trade will not require the tub-ſhaft, tub or its geer; and the ſame may be added without interrupting the trade, when at any future time it ſhall become an alternate one.

Mr. *Fulton* next deſcribes (page 71.) his ſingle inclined plane for great heights; here, his wheel-boats are to aſcend and deſcend on the ſame rail-way on his plane; the leading chain winds round a barrel or drum, that can, by means of geer that caſts in and out, be moved with two different powers and velocities, by a water-tub working another barrel at the head of an upright ſhaft as before deſcribed; or the tub-ſhaft geer can be entirely caſt off, for the tub to aſcend, or for a boat to deſcend on the long plane, regulated by a brake or fanner as before mentioned. Mr. *Fulton* propoſes his leading-chain, wheel or barrel, to be ſo placed over the bridge between the upper and lower planes, and with a roll or ſmall drum below it, that the leading chain hooked to one end of the boat may drag it out of the upper canal on to the bridge, and lower it down from thence without unhooking, and the ſame in aſcending. Mr. *Fulton* (at page 76.) propoſes for ſmaller riſes, inſtead of a tub-ſhaft, tub or its geer, to erect an overſhot water-wheel, to be ſupplied from the upper level, with proper geer, and a drum for one end of a chain to wind round, the other, after paſſing over two pulleys at the head of a plane, (one pulley would anſwer better, by placing the water-wheel or its drum oblique to ſuit the ſame) to be hooked to the ſtern of the laſt of three or more boats that are to aſcend, each of the boats before it being in like manner hooked by their own chains to the leading chain, according to the weight of the boats, and the power of the water-wheel; when water is let on to the wheel, theſe are to be dragged up, and diſcharge themſelves one by one, and ſlide down into the upper canal; boats are to be dragged up, ſingle or more than one, out of the upper canal on to the bridge, and when they begin to preponderate towards the deſcending plane, the water is to be ſtopped from the wheel, which is to be allowed to turn backwards, and act as a fly or regulator to the velocity of the boats in their deſcent. The water-wheel will not often admit of being ſupplied from the lower level, as Mr. *Fulton* has ſuggeſted, on account of the great expence or the impracticability of a drain or ſough to diſcharge its water; the ſame difficulties, as Mr. *Chapman* has obſerved, attend ſeveral of the tub-ſhafts which Mr. *Fulton* has propoſed, for the perpendicular lift of boats from one level of a canal to another, of which we ſhall treat hereafter. At page 37, and fig. D, in his 5th plate, Mr. *Fulton* has recommended his wheel-boats, to be uſed, on a ſingle aſcending plane to a coal-pit mouth, to be drawn up the ſame by a chain winding on a drum, worked by the mine-engine, and lowered down the ſame by means of a brake attached to the drum.

On the 2d of Auguſt 1796, Mr. *John Luke* took out a patent for an inclined plane, on which boats in a cradle are to be drawn up, by the deſcent of a water-tun on another plane, aſſiſted by a water-wheel in certain parts of its motion, or in ſcarcity of water, by a hand winch. See *Monthly Magazine*, vol. ii. page 652.

Mr. *William Chapman* recommends an improved kind of inclined plane in his *Obſervations*, &c. of which he has given an account at page 96., "by making the deſcending and aſcending way continuous, like Mr. *Fulton*'s; and having a lock at the head of the deſcending way, long enough to contain a ſeparate carriage for three or four boats (or ſo many as form what has been called a conjoined boat). Theſe boats, on deſcending, would draw another gang light, or half loaded upwards, over the top of the ridge, no lock being requiſite on that ſide. The chief objections to this, lie in the vaſt weight of a gang of boats, which, in a ſteep angle of deſcent, would require a very heavy rope, and in the difficulty of returning the carriages to their proper place. The latter may be got over by keeping the two ways at a little diſtance, and joining them above and below by a ſemicircular rail-way for the carriages; coupled to each other (in ſuch a way as to ſuit the different boats that are to reſt upon them, and yet admit of the neceſſary extenſion, when the boat came over the concave part of the inclined plane, which may be affected by a worm ſpring) to run along under water, after they have parted with their veſſels. Both in this and the method laſt deſcribed, the water contained in the lock may be drawn off into a reſervoir, at the head of the inclined plane; in this reſervoir, or a pond communicating with it, may be fixed a broad underſhot water-wheel between the two rail-ways, to retard the motion of the deſcending boats and throw back the water. This wheel may run in a cloſe caſe, and be divided round its periphery by different ſhroud boards, forming ſo many wheels that one or more portions of its width may be employed at the ſame time in throwing up water according to the neceſſity of the caſe, to be determined by the velocity of the deſcending boats, which by means of a centrifugal regulator" (the flying-balls or governor uſed in Bolton's engines, windmills, and other machines,) "will open one or more of the penſtocks to let water below the wheel, or ſhut them all as occaſion may require. The reſervoir under the wheel ſhould of courſe never be exhauſted, but when drawn down to a certain extent ſhould by a floating weight or any other method let in water from the head canal. Theſe means will anſwer for a deſcending trade, and if the aſcending trade be more that the other can draw up and water be deficient, recourſe may be had to a ſteam-engine."

We have thought, that a different kind of lock at the top of an inclined plane might be uſed with advantage, compoſed of a rectangular box, water-tight, except one end, which ſhould be open, and having wheels under it of different heights, ſo as to ſupport it upon the plane in an horizontal poſition, its ſize being juſt ſufficient for a boat to float into it. The end of the upper canal ſhould terminate in a ſingle lock-gate, the outſide border or edges of which ſhould be leathered, or covered with liſt; ſo that when the carriage or cradle above deſcribed is drawn up to the top of the plane, its open end ſhould fix itſelf againſt the lock-gate opening, in a water-tight manner, by means of wedges or ſcrews prepared for the purpoſe of confining it; a ſmall ſhuttle in the lock-gate might then be opened to admit water to fill the cradle, making it act as the chamber of a lock; the lock-gate being opened, a boat might enter the cradle, from which it would expel great part of the water into the upper canal again, if the boat and cradle were nicely adapted to each other; the lock-gate and ſhuttle ſhould be again ſhut, when the water might be drawn off into a ciſtern, (to be returned if neceſſary by a water-wheel or any of the methods before mentioned), the cradle be unfaſtened from the lock, and be let down the plane by any of the regulators before propoſed. For paſſing the boat out of this cradle at the bottom of the plane, the back or other end of the cradle might open, or, perhaps a better method would be to continue the plane deep enough into the lower canal, that the cradle, which ſhould in this caſe be heavy enough to ſink in water, might deſcend low enough for the boat to float out or in, over its end; ſide rails ſhould, in this caſe, ſtand up from the cradle, to ſhew its place when under water, and for guiding and fixing the boat over it, with liberty to ſink into the cradle, as it is drawn up the plane to the ſurface of the water.

Mr. *Chapman* informs us (page 7.), that for avoiding the friction of the gudgeons of rollers, when charged with the weight of a loaded boat on an inclined plane, *Earl Stanhope* has propoſed, that rollers between the boat's bottom and a ſmooth plane ſhould be uſed, moving or rolling with the boat, for half the boat's length; the rollers then to return to their places by means of weights acting over pulleys, and connected by a chain to the ends of each roller. Mr. *Fulton*, he ſays, propoſes to uſe moving rollers, attached to, or going under and through the cradle that contains the boat, the gudgeons at the ends of the ſeveral rollers being paſſed through the links of an endleſs chain or collar, by which the rollers are returned in a cavity under the boat, that is reſting in the cradle; this endleſs chain of moveable rollers for leſſening of friction, appears to be claimed as part of *A. G. Eckardt*'s patent of the 31ſt of January, 1795, for various machinery: ſee *Repertory*, vol. ii. p. 365.

The principles of ſetting out canals, where inclined planes are to be uſed, are ſimilar to thoſe we have explained, in recommending ſeveral locks to be brought together to form a ſet of ſuch, or a conſiderable fall in one place; it will, however, be neceſſary, in determining the place for an inclined plane, to chooſe ground which ſlopes as regularly as poſſible between the intended upper and lower levels; if any part of the ground for the intended plane is ſpringy and diſpoſed to ſlip, the ſprings muſt be cut off by effectual and durable under-drains. It will be better ſo to contrive the plane, if practicable, that little, if any, filling up of hollows ſhall be neceſſary in forming the plane, to avoid new made ground, which on a conſiderable declivity would perhaps ſlip, after heavy rains had ſaturated it with water; the foundations for the ſtones or bearers muſt alſo be carried through ſuch new made ground, and into the firm-ſtuff. The ſtuff which is removed in forming an inclined plane, ſhould be carefully levelled, or diſpoſed of in holes, ſo as not to form ſpoil-banks, and be covered with the top ſoil previouſly taken from thoſe places. In caſe a perpendicular ſhaft and ſough thereto is wanted at the head of the plane, the knowledge of the *ſtrata*, or matter which compoſe the hill, may be of conſiderable importance, in determining the beſt place for the mouth of the ſough; which may not always be the neareſt point at the proper level, to the intended ſhaft, if the *ſtrata* or meaſures of the hill are various and dip conſiderably. The plane being formed of a ſufficient width on the ground, a ſtrong framing of timber braced acroſs may be uſed, if good and durable hewn ſtone is not in plenty, fixed firmly down to a ſufficient number of piles drove into the ground, the interſtices between the framing being filled with good rubble ſtone, or gravel rammed very tight down. On theſe frames two or four ſils or rails of ſound oak, according as the plane is to be ſingle or double, ſhould be laid parallel and at the proper diſtances from each other, and firmly bolted down; and on theſe the ſlips or ribs of iron are to be evenly and ſmoothly fixed, for the wheels of the boat, or boat-cradle to run upon, and upon which they are to be confined from getting off ſideways, by a rib ſtanding up for that purpoſe, either upon the wheels or on the rails. If good ſtone is in plenty, it will be proper to cover the whole of the plane with aſhler or well jointed ſtones, taking care that the courſes acroſs the plane at proper intervals are formed of large ſtones let ſome diſtance into and firmly bedded in the ground; and to theſe the caſt-iron rails (that are uſed on good and durable planes) may be faſtened by pins caſt into a hole with lead. Or, if wooden rails are to be uſed inſtead of caſt-iron ones, ſtrong ſleepers of wood ſhould be worked into the paving of the plane at proper intervals, on which to bolt and faſten down the rails. Care ſhould be taken, in all works of this kind, where large or hewn ſtones are uſed, to let no part of the mortices or holes which are cut in ſuch ſtones remain open or unfilled with lead or cement, to prevent the rain filling them with water, which would in winter time expand with the froſt, and in moſt inſtances ſplit the ſtone. It is unneceſſary for us to point out to experienced engineers, the great care and precaution which ought to be uſed in works of this nature, to make every thing ſubſtantial and more than ſufficient to ſuſtain the weight or ſtrain to which it will be ſubjected, and which ought in moſt caſes, particularly the moving parts, to be previouſly calculated, and before the apparatus is put together for actual uſe, every rope, chain, framing, wheel, &c. &c. ſhould be ſubjected to a greater ſtrain than can occur in practice, to avoid the unpleaſant, and perhaps fatal accidents, which might otherwiſe happen, by which a prejudice might at the onſet be excited againſt the ſcheme, ſo powerful as to cauſe it to be laid aſide without proper trial. It would much exceed our limits to enter fully into this ſubject, we ſhall therefore proceed to thoſe other contrivances for overcoming aſcent on canals, where boats have been lifted out of the water, or propoſed ſo to be, by a perpendicular aſcent; after which, there will ſtill remain to deſcribe thoſe methods which require the ſhifting of the cargoes of boats into other boats, or to rail-way waggons, &c.; firſt mentioning that on the *Shrewſbury* canal, an inclined plane is uſed for paſſing the boats over part of the aſcent, while locks are uſed for the other parts; and Mr. *William Chapman*, at pages 54 and 99 of his *Obſervations*, &c. recommends whenever coals in large quantities, lime, lime-ſtone, or other minerals, are to be conveyed along canals, or are brought in by branch canals on a ſmall ſcale, there being a ſcarcity of water which reſervoirs cannot remedy, where it can be done in ſetting out the canal, in addition to the locks, to overlap the levels in a ſteep place, and communicate them by an inclined plane for boats (or a double rail-way for tram-waggons) leaving the lock communication to anſwer all the general purpoſes of commerce. The ſame author obſerves, that the porterage of articles from one level to another, and carriage of the boat itſelf is ſtill practiſed in various parts of North America, as the falls of the Mohawk, from the Mohawk to Wood Creek, at the falls of Orandaga, &c.; alſo at ſeveral places called Tarbets, in the Highlands of Scotland, as in Cantyre, Loch Lomond, Arrachar and Long, Jura, &c. Among the principal inclined planes for boats, are thoſe of Hay, Windmill-hill, and Wrockardine-wood on the *Shropſhire* canal, Walkden Moor on *Bridgewaters'*, Ketley on the *Ketley*, Wormbridge on the *Shrewſbury*, &c.

On the 8th of May, 1794, Mr. *Robert Fulton* took out a patent, as before-mentioned, in which he deſcribes (ſee *Repertory*, vol. vii. p. 227.) either a rectangular upright notch in the ſteep face of a hill, to the top and bottom of which the two levels of a canal are brought, or a large perpendicular ſhaft and tunnel at the bottom for the lower canal, through which notch or ſhaft boats are to be drawn up or let down, in a pair of water-tight cradles, ſuſpended at the two ends of ſtrong ropes of chains, that are to paſs over pulleys fixed above the top of the ſhaft, and connecting with a brake-lever or wheel, to regulate the deſcent of a boat in one cradle, and aſcent of another in the other, after they have been brought to an equilibrium by the letting out or in of water by proper valves. The boats are to be drawn into and out of the cradles, by ſhort inclined planes, in the upper and lower canal, on which the boats on wheeled carriages are to be drawn by ropes winding on the axis of water-wheels, to be turned by water let out of the upper canal thereon; brace-blocks are to be uſed for adjuſting the length of the great rope, and capſtans may be uſed inſtead of water-wheels, for paſſing the boats on and off the cradles. Mr. *Fulton,* in plates 11 and 12 of his "Treatiſe on Canal Navigation," and his deſcriptions thereof (pages 97 and 100) has more fully deſcribed this method; and propoſes for a deſcending trade, that the full boats ſhould draw up the empty ones, and inſtead of inclined planes for getting the boats on to the cradles, a cage of iron ſhould be uſed, into which the boats on the lower canal can be floated; and for diſcharging them into the upper canal, he propoſes two lock-carriages, or large water-tight boxes, open at one end, moving on iron rail-ways, and which can be advanced by racks and pinions over the ſhafts, while the boat is ſuſpended high enough to clear its bottom; the open end of this lock-carriage is made to fit, and be retained againſt the frame of a lock-gate at the end of the upper canal, (as in Dr. *Anderſon's* and *Fuſſell's* methods, and the water-tight cradle which we have lately mentioned), when the water being admitted by a valve, to float the boat in the lock-carriage, to the level of the upper canal, the lock or draw-gate thereof is to be opened, and the boat floated out of the cage to proceed on the upper canal; to the pulleys or drum-wheel over which the chains act, a fly or fanners is propoſed to be connected to regulate the motion; as alſo an axis with cranks to work pumps, by which the water that is drawn off again from the lock-carriage into a ſide reſervoir may be pumped up again into the upper canal, that no water may be loſt. For an alternate trade, to which it may be at firſt adapted, or the neceſſary parts applied afterwards, an additional ſhaft muſt be ſunk, in which a water-tub is to be ſuſpended, inſtead of another cage and boat, as a preponderating weight; this is to be filled out of the water reſerved in a ciſtern that is drawn out of the ſliding lock-carriage.

Mr. *Robert Fulton* (ſee his "Obſervations," p. 94. and plates 9 and 10.), particularly deſcribes a ſpecies of Cranes, by which boats are intended to be drawn up, in an iron cage, through an upright notch or ſhaft, and by the motion of the jibs, are to be moved over the upper canal and lowered down to float thereon, or the reverſe in deſcending; for this purpoſe a perpendicular notch or ſhaft for the boats, and another for a water-tub, as a counter-acting and motive force, is to be provided; a reſervoir is to be formed by the ſide of, and about 8 feet from the bottom of the tub-ſhaft, into which the water diſcharged from the tub, when at top, can be conveyed by a proper valve and ſpout; proviſion is to be made, by valves and ſpouts, for filling the tub from the upper or lower level of the canal, as occaſion may require; and a valve is to be provided, opening by a pin in its bottom, for diſcharging the water when it reſts on the bottom of the tub-ſhaft; over the tub-ſhaft a drum is to be fixed, for the tub-chains and crane-chains to wind round, and to this drum a fly or fanner is to connect by toothed wheels and axles, to regulate the velocity of the motion. The crane-chains are to be double, and proceed to two ſeparate jibs fixed on centres, at proper diſtances from each other, having the ends of their jibs connected by a coupling-rod of the ſame length, by which they will always move parallel, and ſuit the diſtance of the hooks on the top of the iron boat-cage. For raiſing a boat out of the upper canal, the ſame being floated on to the cage ſuſpended from the cranes or jibs, and the water-tub (to which balance-chains are to be adapted) being near the bottom, water is to be drawn, by a valve and ſpout, out of the reſervoir into the tub, till it preponderates and draws the cage and boat out of the upper pound; the jib is then to be moved over the boat-ſhaft, and the water emptied from the tub by ſuffering it to deſcend a little farther and ſtrike the bottom, when the boat will be lowered eaſily, by means of the fly, to the lower canal, where it can be floated out of the cage; and the reverſe on aſcending. If water is very ſcarce in the upper canal, and a ſough or tunnel can readily be driven, for emptying the tub-ſhaft, the ſame may be made deep enough to draw water from the lower inſtead of the upper canal, for the preponderating power. We have not heard that any of theſe perpendicular lifts for boats have been executed, we ſhall therefore proceed to the other kinds of cranes and perpendicular lifts for the cargoes of boats.

Mr. *Bridge*, of Tewkſbury, about the year 1759, contrived, for the navigation on *Stroudwater* river, a kind of cranes, with double jibs, that could be either uſed ſingly or together, and act as a balance to each other; theſe were erected on a ſtrong walled bank, that ſeparated the upper and lower levels of the river at the ſeveral mills. The boats to be uſed on each different level, or mill-ſtream and dam, were all of one ſize, and made exactly to ſuit and contain a certain number of ſtrong wooden boxes, without any loſt ſpace. The goods or lading of the boats were placed in theſe boxes, and when they arrived at the firſt crane, one end of the chain thereof was hooked to a box, while the other was hooked to a ſimilar box of goods in the other level, and by a peculiar ſtructure of the crane, worked by two men at windlaſſes, both boxes were drawn up and ſuſpended, ſomewhat higher than the bank of the upper canal, when the jibs were turned half round, and the boxes of goods were lowered down and replaced each other in the boats; the ſame operation was repeated with each of the remaining boxes, when each boat was ready to proceed with its new lading upon its own level to the next cranes. It can hardly be neceſſary to add, that the expence and delay of this method cauſed it to be ſoon laid aſide.

Mr. *Edmund Leach*, in his treatiſe before quoted, propoſes boats to be unladen and laden with boxes of goods as above, but to work the cranes by water-wheels, or by wheels for men to walk in.

The *duke of Bridgewater*'s tunnel from his canal into the coal-works at Worſley, after it had proceeded for a great way ſtraight into the hill, came at a great depth to be under a ſmall brook or conſtant ſtream of water, by the ſide of which a large water-ſhaft was ſunk, and a drum and large brake-wheel erected over it, of ſufficient ſize that a man who ſtands before the lever thereof has his two hands at liberty to pull the lines which connect with the valves, and give ſignals to thoſe below, while by lunging, or ſtepping forwards, with his breaſt againſt the lever, he can in an inſtant ſtop the machinery in any part of its motion, or regulate the ſame at pleaſure. There are two water tubs, which are very large and have a valve and pin to empty themſelves quickly when they arrive at the bottom; they are ſuſpended by large ropes or cables from the drum, while other large ropes deſcend therefrom through another, or coal ſhaft, by the ſide of the middle or principal tunnel, into and over the navigable tunnel, which there is at, we believe, 60 yards lower level. On this loweſt canal boats are uſed, ſimilar in their dimenſions to thoſe above, and containing boxes, which being filled with coals at the ſeveral terminations of this canal, in the ſeams of coals; the boats are puſhed along by means of rings that are fixed all along the roof of the tunnel, at the proper height for a man, who walks on the top of the coals, to lay hold of, and ſhove the boat along by. The boat being arrived under the coal-ſhaft, and one of the water-tubs being at the top of its ſhaft, the coal-rope anſwering thereto is hooked on to the box of coals, and the deſcent of the water-tub, immediately on the ringing of a bell, draws up the ſame to the level of the principal canal, where being drawn aſide over an empty boat, it is lowered into the ſame by a ſlight reverſion of the motion of the machine; when the interval of emptying the tub at the bottom by its valve, gives time for hooking another box to the other rope which is at the bottom, when the other water tub is filled, and the machine ſuffered to move, by the man who leans againſt the brake. This very complete and economic machine was contrived and erected by Mr. *James Brindley*, and it is ſo conſtructed, that when coals are not drawing, the alternate deſcent of the water-tubs work ſome very large pumps, which are ſufficient to lift all the mine-water of the lower level into the middle canal and keep the lower canal always at the proper height for navigation.

The ſame tunnel of *Bridgewater*'s canal being continued a great way further into Worſley hill, till under Walkden moor, another ſubterraneous canal or tunnel there begins, at 35½ yards higher level, this laſt being near 60 yards from the ſurface; from the ſurface two ſhafts were ſunk, one terminating in and over the upper tunnel or canal, and the other in and over the middle or principal canal; there is another canal ſtill lower, which we have been laſt ſpeaking of, after paſſing cloſe by the canal above: between theſe ſhafts a large drum was erected on the ſurface, with a brake wheel and a pair of ſtrong ropes. Two boats being arrived at the ſhafts on the upper canal, one of them loaded with boxes of lime-ſtone, that was wanted at the ſurface, and another with boxes of coals intended to be transferred into an empty boat in the middle canal; the ends of the two ropes were faſtened to a box of coals and a box of lime-ſtone, when the ſuperior ſize and weight of the coal-boxes drew the lime-ſtone to the ſurface, to be there landed and depoſited, at the ſame time that the box of coals was depoſited in the lower boat, ready to proceed on the canal to Mancheſter or other places. This method was in 1797 ſuperſeded by an inclined-plane for letting down the boats laden with coals, from the higher to the middle level, and returning the empty boats and boxes, as we have before-mentioned. At Brierly-hill, near Coalbrook-dale, the extremity of a branch of the *Shropſhire* canal, great quantities of coal and iron in crates made of iron were let down one of two ſhafts, which connected, with the termination of the canal above and the ends of a rail-way in a tunnel below, from which lime-ſtone in ſimilar crates was drawn up the other ſhaft to be placed in the boat; a large barrel and brake-wheel were fixed between the tops of the ſhafts, and cranes with jibs, by which the crates could be raiſed and moved from the boat over the ſhaft, or the reverſe; theſe ſhafts, which were 120 feet deep, were not found to anſwer, in point of expence, ſo well as inclined planes, and Mr. *Telford* informs us (*Plymley's Report*, p. 296 and 307.) that inclined planes have been ſubſtituted, on which crates of coal, or iron pigs, or goods, deſcend and draw up other crates containing lime-ſtone, for the uſe of the iron-works above, by means of ropes, a drum, and brake-wheel, with a much leſs portion of manual labour, and more expedition, than was done by the ſhafts above-mentioned. Near Lilleſhall lime-works, on *Donnington Wood* canal, ſimilar ſhafts were once uſed, but are now ſuperſeded by an inclined plane. At Coombe-hay, on the *Somerſetſhire Coal* canal, after the trial of Mr. *Weldon's* diving caiſſon, inclined planes for deſcending boxes of coals were erected, and uſed for ſome years; but the delay and expence were found ſo great, that the company effected the purchaſe of ſome mills, and under a new act of parliament, erected 22 locks in place of theſe inclined planes. Having finiſhed with the different kinds of inclined planes, and other ways of procuring the aſcent of boats or their cargoes, we proceed to thoſe which are uſed for overcoming the principal or ſudden aſcents on rail-ways or tram-roads; whereon waggons or trams are uſed for the conveyance of goods, the ſame being drawn on the level parts or eaſy aſcents or deſcents by a horſe, as we ſhall deſcribe ſhortly.

Mr. *John Buddle*, in the *General Magazine* for 1764, page 285, has given a view and deſcription of the coal-waggon which had been then long in uſe on the wooden rail-ways in the neighbourhood of Newcaſtle upon Tyne. This waggon moved on four wheels of caſt-iron, or of wood with iron rims, having an edge ſtanding up on the rim of each wheel, in order to guide and keep them upon the wooden rails. The waggon is in ſhape of an inverted priſmoid, having a door or falſe bottom hung with hinges and faſtened by a haſp, that can be let go to let out the coals when the waggon has arrived on the ſtaith, and over the ſpout which is to convey the coals into the ſhips or keels, or into a heap below as a ſtore; obliquely over one of the hind wheels a ſtrong crooked lever of wood is fixed and ſuſpended, by a ſtrap when not in action; this lever, called a convoy, is intended to act as a brake, by being let down upon the wheel when the waggon is deſcending down an inclined-plane, or ſteep part of the rail-way called a run; and on theſe occaſions the horſe is unharneſſed from the front of the waggon and tied behind, and the waggon-man mounts aſtride on the hinder end of the convoy, the fore-end being confined cloſely in a ſtaple in the ſide of a waggon; and, by means of a reſt that there is for his feet at the tail of the waggon, he applies juſt ſo much of his weight upon the convoy as will either ſtop the waggon or give it the proper velocity in every part of its deſcent down the hill or run: ſee the *Agricultural Magazine*, vol. iii. p. 241. In the year 1783, we remember ſeeing an inclined plane or waggon-way as above deſcribed, on which the coal waggons deſcended down the hill from Wibſey-ſlack to the town of Bradford, which is on a branch of the *Leeds and Liverpool* canal, their velocity being regulated by convoys as above. But ſome waggons which we have ſeen, had the convoy fixed to a moveable joint at the front of the waggon, and had a large block of wood thereon, which, when the convoy was let down, wedged in between the fore and hind wheels, and acted moſt ſecurely as a brake for ſtopping or regulating the velocity of deſcent. The empty waggons were drawn up the hill again to the coal-pits by a horſe.

An *inclined plane for waggons*, was erected ſome years ago by Mr. *Barnes*, a coal viewer at Bywell, near the *Tyne* river, of which a deſcription is given in the *Agricultural Magazine*, vol. iii. p. 367, as follows: "It is a very ingenious, yet ſimple combination of machinery, for the purpoſe of regulating the conveyance of waggons laden with coals down an inclined plane, and for bringing the empty ones back again, by the ſame power that reſiſted its impetus in the deſcent. The length of the rail-way in which the waggons

gons run is about 864 yards, which diſtance it deſcends in two minutes and an half, and re-aſcends in the ſame ſpace of time; ſo that the loaded waggon can be let down with eaſe and ſafety, the coal diſcharged and the empty waggon returned to the pit within the compaſs of ſeven minutes. The impelling and reſiſting power of motion are derived from a plummet of 16½ cwt., which the waggon in deſcending and aſcending alternately raiſes and lowers to the depth of 144 yards. The rope, by which the waggon is impelled and accelerated, winds round the axis of a large wheel in a nich or groove in the middle, which gives the rope only ſpace to coil round upon itſelf, and thereby guards againſt all poſſibility of entanglement. Near to the axis of the large coiling-wheel, there is an oblique indention (a range of teeth or cogs) of caſt-iron, which correſponds with and works into a ſimilar conformation on the rim of a ſmaller wheel; round which the plummet-rope is coiled or warped, and it is in conſequence thereof moved round, only once in ſix rotations of the ſuſpending and retracting wheel, which is the ſame proportion that the elevation of the plummet weight bears to the deſcent of the waggon; to preſerve the rope from injury by dragging on the ground, rollers with iron pivots and braſs ſockets for it to run upon, are elevated in the middle of the rail-way, but ſufficiently low to prove no obſtruction to the waggons which paſs over them." On ſhorter inclined planes than the above, horſe-gins are ſometimes uſed, for drawing loaded waggons up, and at the ſame time letting empty waggons down the planes.

The *conſtructing of Rail-ways*, or, as they are often called, tram, dram, or waggon-roads, require the application of principles ſo exactly ſimilar, and they are ſo intimately blended with our ſeveral navigable canal and river eſtabliſhments, that we have before mentioned our idea of the impropriety and difficulty of ſeparating them by deferring the account thereof to a future place in our work: the ſubject of inclined planes, of which we have laſt been treating, has required the mention of ſo much relating to *rail-ways*, that we beg to proceed with and finiſh that part of our ſubject, before we reſume the ſubject of bridges, towing-paths, fences, drains, boats, moving boats, &c. which yet remain to be mentioned. From the firſt opening of the coal-mines on the banks of the *Tyne* river above Newcaſtle, until about the year 1680, it appears, that the coals were conveyed in carts and wains, from the mouths of the ſeveral pits, to the keels or veſſels, that conveyed them to the ſides of the ſhips lying below the bridge. As this kind of fuel came to be ſubſtituted for wood in London and other cities, and towns on the ſouth and eaſtern parts of the iſland, the conſumption of Newcaſtle coals became ſo conſiderable, that we are told, that ſeveral coal-mines, as the Kinton, Benwell, Jeſmond, &c. gave employment to 400 or 500 carts or other carriages each, for conveying the produce of thoſe pits to the water-ſide: the difficulty and expence of maintaining ſo many horſes, and coſt of repairing roads for ſuch conſiderable traffic, occaſioned the introduction, about the period above mentioned, of waggon-roads or wooden rail-ways, on which waggons of a large ſize, with wheels of a particular form to ſuit the rails, were uſed, and which one horſe could draw, owing to the regular and eaſy deſcent with which the rails were laid. It was not until the year 1738 that this important improvement was introduced at the White-haven collieries on the weſtern coaſt, and it is truly ſurpriſing to obſerve how ſlow the introduction of them was in other parts.

Way-leaves or ſlips of ground were ſet out and hired on leaſes, or purchaſed by the different coal-owners of the ſeveral proprietors of lands, lying between their pits and the river, and this, not by the neareſt route, but in ſuch a direction as gave the moſt eaſy and regular deſcent. The inequalities of this ſlip of ground were levelled as a road, hollows were filled up, and ſudden hills lowered, when ſleepers or large logs of wood were laid acroſs the ſame, their tops being all of a regular height; upon theſe, two rails, generally of beech wood, were laid parallel to each other, their ends abutting cloſe to each other, and were firmly pegged down to the ſleepers. The tops of the rails were planed ſmooth and round; the wheels of the waggons were low and of caſt iron, or of ſolid wood with iron rims, which were not flat on the edge, but hollow to receive and move on the wooden rails; the inſide edge of each wheel projecting near two inches, in order to confine the wheels effectually to the rails, and prevent the waggon from being drawn off the road. From all conſiderable works, there was a main way made for the paſſage of loaded coal-waggons as above; and another, or bye-way by its ſide, for the return of the empty waggons. When coal-mines had been worked into deeper ground, and pits or ſhafts were opened below Tyne-bridge, the rail-ways therefrom were conducted to the top of a ſtage or wooden building called a ſtaith, on the wharf or key where the ſhips lay; and the coal-waggons, a deſcription of which we have already given, were either emptied at once through the ſpouts into the hold of the ſhip, or depoſited in the warehouſe below in ſtore for future ſhips. One indifferent horſe could in general draw three tons of coals from the pits to the river ſide upon theſe wooden rail-ways; which mode of conveyance became further improved by the introduction of plates of wrought iron nailed on to the rails for the waggon-wheels to run upon. Attempts were made in different parts, to introduce caſt-iron inſtead of wooden rails; but owing to the brittleneſs of the material, and the great weight of the waggons in uſe, they did not in general ſucceed.

About the year 1768, Mr. *Richard Lovell Edgeworth* contrived a remedy for the principal objection to caſt iron rail-roads, in making uſe of two or three ſmaller waggons linked together, inſtead of one large one; a model of three of theſe he preſented to the *Society of Arts* in the Adelphi, London, and was honoured by the premium of their gold medal. In the year 1788, the ſame gentleman, on ſome temporary wooden rail-ways for manuring of land, made ſeveral experiments, in the preſence of different Mechanics, on the application of friction-rollers for diminiſhing the friction of waggon axles. The rail-ways hitherto conſtructed were private property, or for the accommodation of particular mines or works, and it was not, we believe, until about the year 1794, that Mr. *Samuel Homfray*, and others, obtained an act of parliament for conſtructing an iron dram-road, tram-road, or rail-way, between *Cardiff* and *Merthyr Tidvill* in South Wales, that ſhould be free for any perſons to uſe, with drams or trams of the ſpecified conſtruction, on paying certain tonnage or rates per mile to the proprietors. Soon after the year 1797, iron rail-ways began to be conſtructed as branches to the canals of Shropſhire; and, in other parts of England, Mr. *Benjamin Outram*, an engineer, began to conſtruct the ſame upon improved principles, of which Dr. *Anderſon* has given an account in his *Recreations*, vol. iv. pages 199 and 473.

On the 25th of June 1799, the houſe of commons made a ſtanding order for extending to all bills for making any ways or roads, commonly called rail-ways, or dram-roads, all the orders (of May 7, 1794) relating to the introduction of canal bills. One principal difficulty, the proviſion of water, does not here occur, unleſs for docks or baſons, which are not unfrequently neceſſary, at the termination of a rail-way, at a river, or exiſting canal; and, as the owners of ſtreams of water are not under dread of loſing the ſame by the paſſage of a rail-way near them, and the ſame is applicable ſo much more eaſily to the uſes of the owners and occupiers, than a canal is, leſs difficulties will attend the obtaining of general powers for making ſide or collateral branches, at any future period; and of connecting the ſame with different rivers, canals, or rail-ways, making the parties a compenſation in tolls or otherwiſe, if ſuch connection ſhall appear to draw off or leſſen the trade upon any part of their line of communication, as often happens; and ſuch ought always to be carefully inveſtigated, and liberally eſtimated by the engineer, and the company be adviſed to act accordingly.

In ſurveying a line of country for a *rail-way*, principles ſomewhat different from thoſe which apply to a canal, are to be kept in view; in the latter caſe, exact or dead levels are traced out, and the caſe of towing or dragging boats thereon is nearly the ſame in going one way as in returning the other, whether laden or not, for the aſcent or deſcent of the locks or planes are there overcome by a different power than that applied to towing upon the levels; in a rail-way the caſe is different, the horſe which in going one way draws a very heavy load down a ſlight deſcent, has to return again with the empty waggons, or a lighter laden, up the ſame aſcent. It will therefore be neceſſary, as a preliminary ſtep to ſetting out a rail-way, to calculate as accurately as poſſible the quantity of lading which will at the firſt or any future period be to paſs each way upon the line, or on any particular parts of it, becauſe on this will depend, in a great meaſure, the ſlope that it ought to have, and conſequently the ground which the rail-way line ought to occupy. If it ſhould appear, on an accurate calculation, that the ſame weight of lading may be expected to paſs one way as the other, or that the ſame will preponderate at ſome periods one way, and at others the other way, the rail-way muſt in this caſe be ſet out in levels or very nearly ſo, and the unavoidable aſcents and deſcents muſt be made by inclined planes, as before mentioned; on which either a greater number of horſes muſt be ſtationed to draw waggons up, and in letting down, their wheels muſt ſome of them be ſlippered; or loaded deſcending waggons muſt draw up the others; the deſcent of a weight or tub full of water in a ſhaft muſt draw up a waggon, or more than one; or, a ſteam-engine, horſe-gin, or walking-wheel, muſt be uſed as a moving power, with fly or brake regulators of the motion, as we have before mentioned. If the trade will always preponderate one way, as it generally will in the deſcent from mines to navigations, and the ground will admit of the ſame, the regular inclination of the rail-way ought to be ſuch, that a horſe can draw the uſual lading down with the ſame eaſe as it can return with the waggons when emptied, or with a partial lading, in caſe of there being a ſmall aſcending trade. If the ſlope of the ground ſhall be found greater than to ſuit the above calculation, the rail-way ought to be ſet out for as great lengths together as is practicable, with the proper ſlope, and then to ſet out an inclined plane, as before mentioned. It ought to be well conſidered, where a rail-way or a branch from the ſame appears likely to have a deſcending trade at preſent, whether, at a future period, by extending the ſame forwards to any town or manufactory, or by other change of circumſtances, the aſcending trade is likely to be materially increaſed, in proportion to the deſcending; becauſe in ſuch caſe, the line would require to be altered in its ſlope, and moved to a new place, or it muſt continue to be worked to a conſiderable diſadvantage by the horſes having to travel down the line unemployed, to fetch up a portion of the loaded waggons. It will readily be perceived, that the adoption of *the beſt line*, of which the circumſtances of the trade and nature of the ground is ſuſceptible, is a taſk requiring a degree of ſkill and patient reſearch, not at all inferior to any thing required in the ſetting out of a canal, and it can hardly be neceſſary to point out the neceſſity of employing the moſt competent engineer, and allowing him proper time and aſſiſtance, in order to get the moſt eligible line marked out. A rough ſection of the different routes which appear eligible for a rail-way made by levelling with a ſpirit level, will be very uſeful in the firſt inſtance; from which, and a view of the ground, the engineer will be able to determine nearly the place and extent of the inclined planes, or ſteeper parts of the rail-way which will be neceſſary; theſe laſt being always made as ſhort as the nature of the ground and circumſtances will admit. Theſe being ſettled, the line of the intended rail-way muſt be traced on the ground, beginning at the higheſt point, and ſtretching a chain on the ground, one end being held at the point of departure, the other muſt be turned round upon the face of the deſcent, until a point marked by this end is found, which is one link (or ſomething more or leſs, according as the ſlope is to be) lower than the upper end; the chain being now moved forwards, till the hinder end reſts on the point laſt determined, the other end is to be moved, accompanied by the levelling target, until a new point is found, one link lower than the laſt, and ſo on; by which, a line having the regular deſcent of one link in a chain, will be traced out on the ground, until the place of an intended inclined plane is reached. The ſtakes which are put in to mark the place of each ſucceſſive ſtake will, as in the caſe formerly mentioned, of ſetting out a level for a canal, be found very crooked in many places; and it will be neceſſary for the engineer to ſtake out a new line, after a moſt careful view and conſideration of the ground, as the approximate line for the centre of the rail-way; which muſt be without any ſudden bends, that would occaſion friction of the wheels againſt the ſides or ribs of the rails. Single rail-ways will generally require about four yards wide, and double ones about ſix yards wide (excluſive of the neceſſary ſpace for drains and fences), and this width will require to be levelled like a road or plane: it will therefore be proper ſo to ſet out the line, that the quantity of ſtuff which is to be lowered in one place ſhall always, with the leaſt diſtance of throwing or barrowing, make up other places which are too low. Where ſudden valleys are to be croſſed, it will be neceſſary to conduct the line, ſo as to cut into the hill at each ſide of it, to find the ſtuff as readily as poſſible for forming the embankment: it will alſo be neceſſary to ſearch carefully for gravel or ſtones fit for making the road between and under the rails; and if ſuch can be got in the line, it may be a conſiderable ſaving of labour and of damage to the land, as well as a ſource of future advantage to the concern, to cut pretty deeply into ſuch materials, as we have before ſuggeſted and explained on the ſetting out of a canal; which the reader, who wiſhes to underſtand this ſubject, would do well to conſult. A line of ſtakes, exactly at a chain (100 links) apart, ſhould be put into the line laſt ſtaked out, and drove ſucceſſively into the ground, beginning with the higheſt, ſo that the head of each may be very exactly one link (that being the fall we have aſſumed) below the level of the laſt; of courſe theſe will either ſtand above the ground, or be drove in the bottom of a hole, according as the ground wants raiſing or ſinking, and will enable the engineer, on a review of the line, to judge more correctly, or to calculate where neceſſary, whether the line is ſet out in the right place to be formed at the leaſt expence of labour, and with the leaſt damage to the land; and when this is found to be the caſe, the neceſſary width of land can be determined on, and the ſame ſurveyed and deſcribed by the ſurveyor, for the purpoſes of depoſiting the neceſſary plans with the clerk of the peace and with parliament. The different regular ſlopes or parts of the rail-way being determined in this manner, the ſteeper ſlopes or planes that may be neceſſary to join them, muſt next be ſet out and determined, by taking the whole fall or difference of the levels of the two ends, and dividing the ſame by the number of chains that the plane is to be long, for obtaining the fall which is to be allowed between each pair of ſtakes, inſtead of a link as before aſſumed. In ſetting out a ſingle rail-way, it will be neceſſary, at proper intervals, to allow the width of land proper for a double rail-way, for a ſhort ſpace, in order to form paſſing-places for the waggons that are coming different ways. As part of the rail-way will in moſt caſes be conducted along the ſide of a hill, or on ſide-lying ground, it will be neceſſary to conſider the ſame in calculating to diſpoſe of the ſtuff, and for the neceſſary ditches and drains for intercepting the ſprings and ſurface water in every inſtance, ſo that the ground of the rail-way may at all times remain dry. The draining, fencing, and bridges, will require to be done on the principles which we ſhall further on explain reſpecting canals; and the embankments, culverts, or tunnels, which may be neceſſary for preſerving the proper ſlope in all places, are alſo to be done on ſimilar principles to thoſe of canals before treated of. It may be proper here to mention, that Mr. *Robert Fulton,* in his *Treatiſe* before quoted, pages 82, &c. has ſuggeſted and deſcribed different kinds of caſt iron bridges for paſſing rail-ways over valleys, either level acroſs, down one ſlope, and up the other of the valley, or riſing obliquely up; in the firſt and laſt of which he propoſes to avoid any ſolid platform or top for carrying the horſe path, and to tow or drag the waggons over this open rail-way, by an endleſs rope or chain, paſſing over a pulley at each end, which can be ſet in motion by a windlaſs, a deſcending weight, or other power. On the approach to a river or yard, where conſiderable quantities of coals or other minerals are to be diſcharged, it will be proper to keep the rail-way upon a high level, by embankment, or on arches, or on a ſtage of timber, that the waggons may be diſcharged from the top of a ſtaith or ſtage into ſhips or boats, or into carts and waggons, without being moved by manual labour. Rivers, brooks, or hollow roads, muſt be croſſed on bridges whoſe tops are formed to the regular ſlope of the plane; and where roads croſs the intended rail-way, they muſt either be raiſed ſo as to be carried over, or ſunk ſo as to paſs under the ſame; or be made up to the ſame height; and the rails muſt, in that part, have ribs of leſs height and greater ſtrength, and the whole muſt be ſo firmly embedded on maſonry, that the heavieſt carriages, in croſſing, cannot damage it: an inſtance of which may be ſeen in Wandſworth town ſtreet, and at ſeveral other places on the *Surry iron rail-way.*

A conſiderable facility is occaſioned in the *conſtructing of Rail-ways,* after the plan of the whole is ſettled, the act paſſed, the land purchaſed, the work ſet out, and the ground levelled and properly ſettled, by being able to begin in any part where ſtone, gravel, and other materials that are wanted are to be moſt conveniently had, and to work from thoſe places without the heavy expence of common cartage, except for the iron rails or blocks of ſtone for ſleepers, if ſuch are not found upon the line.

We will therefore ſuppoſe the work to begin at ſome point where the line interſects a rubble rock or a bed of good gravel, and the ſurface of the road is to be covered therewith for about a foot thick, and the ſame is to be nicely levelled, and any great or rough and out ſized ſtones ſhould be carefully picked or raked off, that the whole may the ſooner ſettle down and become one compact maſs; theſe large ſtones may be thrown forward upon the unformed part of the road, to be covered with ſmaller and better gravel. This covering of rubble or gravel muſt be nicely raked and levelled and beat or rammed down, to make it as compact and ſolid as poſſible. A great quantity of blocks of hard and durable ſtone muſt be got in readineſs, from 8 to 12 inches thick, and weighing 150 to 200 lb. each; the ſhape of them is not very material, ſo that the bottom is flat, to bed firmly and evenly on the gravel, and the top is to be chiſelled to a level to receive the ends of the iron rails; in the centre of this flat part a hole muſt be drilled about 1½ inch diameter, and 6 inches deep. Two flat and ſtraight gauges of iron muſt be provided with pins riveted into their ends to ſuit the holes in the ſtones; the pins on theſe gauges ſhould be at the exact diſtance on one of them to ſuit the length of the iron, generally three feet, and the other to ſuit the diſtance of the rails apart or breadth of the road, uſually about 4 feet. One of the ſtones being laid in the proper place for the beginning of one ſide of the rail-way, and nicely bedded and rammed down upon the gravel, another ſtone is to be laid at 4 feet diſtance for the other ſide of the road, and for bringing them to the exact diſtance and level, the pins of the breadth-gauge are to be entered into the holes in each ſtone, and a common or maſon's level is to be applied to the top of the gauge; if the ſtone laſt laid is found too high or two low, it muſt be lifted up again, and gravel muſt be raked out, or more fine and good gravel ſprinkled in and rammed down, until the right height is obtained; the ſtone is then to be laid on again, and brought to its proper place by means of the gauge and level; care is to be taken that the top of the ſtone is level, ſo that the flat ends of the guage bed exactly and evenly on the ſtone all around the hole; and if this is not the caſe the chiſel muſt be uſed to take down any irregularity and produce this bedding of the gauge bar. A third ſtone is then to be laid on one ſide and the length-gauge pins entered into the holes, by which the exact and proper diſtance of the ſtones will be aſcertained, and for trying the truth of this ſtone as to height, a level is to be uſed, in which a line is very carefully drawn by the engineer, making the exact angle with the perpendicular line that the rail-way is to make with the horizon; this being applied upon the length-gauge will ſhew whether the ſtone laſt laid requires more gravel under it, or any to be taken out, obſerving always to level the gravel carefully and to ram it down, and alſo to ram the ſtone down upon the gravel, before each ultimate trial of its proper poſition as to level, its diſtance meaſured by the gauge from the other ſtone, and its range by a line ſtretched in direction of the intended rail-way. With theſe precautions the ſtones are to be ſucceſſively laid, and gravel of the beſt quality, and without any large ſtones, is to be laid in, to fill up the ſpaces between them; and ſome on the outſide of the ſtones, the better to ſecure them in their places; and when a certain length is done, as no mortar or other ſoft material is uſed which requires time to dry or ſet, the work is ready to receive the rails, and will be then immediately fit for uſe, to carry forward the gravel, ſtones, and other materials for the work as it proceeds. We have before mentioned that the ground work ſhould be ſettled; and for this purpoſe the levelling of the road ſhould be performed early in the winter, and the rains and froſt will effectually ſettle it, by the time the work gets dry enough in the enſuing ſpring;

before which, the work ſhould be carefully gone over again, to level and fill up any parts which have ſettled more than was expected and allowed for.

The *caſt Iron Rails*, in the earlier uſe of them, as on the extenſion of the Caldon branch of the *Trent and Merſey* canal, to Mr. *Gilbert*'s lime-works, 4 miles in length, (which was in uſe long before 1794,) were faſtened down upon longitudinal rails of wood, which lay acroſs ſeveral wooden ſleepers, embedded in the gravel, as we have deſcribed above; theſe rails were three feet long, and had two holes, at 18 inches apart, to receive the wooden pins which faſtened them down, or rather confined them in their places, on the wooden rails: (ſee *fig.* 31, *Canals, plate* iv.) at one end there was a triangular projection, and at the other a ſimilar notch which fitted into each other; a rib ſtood up along one ſide, to confine the waggon wheels to the track; and oppoſite the holes, the rail which was about 1¾ inch thick and weighed about 42 lb. was made wider to ſtrengthen that part; yet, with this precaution, ſuch rails were very liable to break in two at the pin holes, as well as to looſe their connecting triangular piece; the rib alſo was very liable, by the wheels or other things ſtriking againſt it, to get broken off near the ends, and the waggons were not confined from running off the road in ſuch places. The rails of the *Surrey Rail-way* are repreſented in *figs.* 32 and 33, and are, we believe, of the moſt improved conſtruction; they have their ends reſting on ſeparate blocks of ſtone embedded in the gravel as above deſcribed, and, inſtead of pin-holes through them, each rail has a ſimilar rectangular notch in its end, which, when two of them are laid cloſe together, forms a counter-work-hole for a ſquare and headleſs ſpike of iron, that is to faſten the ends of both the rails. Theſe rails conſiſt of a rectangular plate of caſt iron, 3 feet 2 inches long, 5 inches broad, and 1 thick; a piece of metal about half an inch thick is added in the caſting, to increaſe the thickneſs at each end for 5 or 6 inches in length, where it is to bear on the ſtone and receive the ſpike; a rib is caſt on to each edge of the rail, one of them above, and ſerves to guide and confine the waggon wheels; the other below for adding ſtrength; theſe ribs which are about three-fourths of an inch thick form by their top the ſegment of a large circle, being about 3¾ inches high in the middle, and about 1½ inch at the ends, by which theſe ribs are calculated to give the greateſt ſtrength to the rail in the middle, where it has no bearing, and to make them not to be eaſily ſnipped or broken off, as mentioned of thoſe rails above, whoſe ribs are of an equal height throughout; ſmall circular projections of metal are caſt on to the width of the rail near each end, and the ſame are carefully bedded upon the ſtone, for preventing the rail from being overturned laterally, by the action of the wheels againſt the rib. For croſſing of common roads, the rib, (ſee *fig.* 34,) is made only an inch high throughout, and near an inch thick, and its edges are well rounded off. In theſe ſituations, a few rows of pavement, of good ſquare ſtones, ſuch as the carriage way of the ſtreets of London are now paved with, are kept nearly or quite as high as the ribs of the rails, by which the heavieſt waggons, carts, and coaches paſs over them almoſt without any ſenſible jolt. Croſſing-rails are uſed at every paſſing-place, or point where waggons are to paſs out of one track of rails into another, which are very numerous in the company's yard, by the ſide of their baſon or dock for barges, in order that empty waggons or thoſe loaded may be readily puſhed into one of the tracks further off the wharf, to let other full or empty ones advance, on their proper track, to the ſides of the barges. A B C D, *fig.* 35, repreſents one kind of croſſing-rails, ſhewn in connection with four common rails, parts of which are repreſented by E, F, G and H; a wedge or tongue of wrought iron, I, is moveable round a pin, and is repreſented in the figure, as placed againſt the ſtub K, ſo that the track from G to F is clear for one of the wheels of a waggon; and by moving the wedge I till it reſts againſt the ſtub L, the track from H to E would be clear; before the waggon can paſs in the directions above-mentioned, the wedge will often want moving by hand to the proper poſition, but in going in the oppoſite direction from E to H, or from F to G, the action of the wheel againſt the wedge will always move it into the right poſition; there is a circular guard or ſtub caſt on to the rail behind the joint of the wedge for preventing the wheels from ſtriking directly againſt the end of the wedge.

The method in which the rails are faſtened to the blocks of ſtone on which they reſt, is by an octagonal peg or trunnion of good ſound dry oak, fitted to the hole in the ſtone, ſo as to drive eaſily into the ſame, otherwiſe its ſwelling by wet and the driving of the ſpike might ſplit the ſtone, this plug of wood is not long enough to reach the bottom of the hole, and is ſawed off even with the top of the hole; a hole is then bored through this plug of wood, and an iron ſpike with a flat point, and a head juſt fitted to the counter-ſunk notch in the ends of two rails, when applied endways together, is drove; by which the rails are ſufficiently confined, and yet in caſe of any wear or ſettling of the ſtone, ſo that the rail gets a little looſe, it is capable of moving that ſmall ſpace without breaking out the ſides of the pin-hole in the rails. It will be proper, always to drill a ſmall hole from the bottom of the plug-hole, quite through the ſtone, for the rain water to ſoak away into the gravel, otherwiſe the freezing of water in the holes would often burſt the ſtones. Care muſt be taken from time to time, to keep the tread or ſurface of the rails clear of dirt or ſtones, which laſt would ſtop the waggon, and perhaps break the rails; and too much pains can hardly be taken by raking and ſorting the gravel, for the finiſh or top of the road, and rolling or ramming of it down, to ſettle the ſame into a compact and hard road as ſoon as poſſible, having no looſe ſtones, which the horſes are always kicking on to the rails, and while this is the caſe, the man who attends the waggons ſhould always go before his horſe, and look carefully to the rails, and remove any ſtones that may have got upon them. The waggons in moſt general uſe on the *Surry iron Rail-way* weigh, including their loading, about 3¼ tons, the wheels are two feet five inches high, of caſt iron, with 12 ſpokes, which get wider as they approach the hub, which is eight inches long to receive a ſmall wrought iron axle; the fellies or rims of the wheels are two inches broad, and nearly as much thick, and the ſharp angles are rounded off, ſo that theſe wheels are capable of being uſed without damage on any hard common road; a very principal advantage attending the modern uſe of rail-ways. The axles of the wheels are fixed at two feet ſeven inches diſtance; the bodies of theſe waggons are ſeven feet nine inches long, four feet five inches wide, and two feet four inches high; theſe are uſed for bringing down chalk from the Surry hills to make lime, carrying back manures, &c. The founders, and others upon the line, have trucks or waggons of different kinds to ſuit the nature of their goods; the only apparent limitations being in the width of the wheels and carriage, the length of their axles, and weight of lading.

For the more ready emptying or ſhooting the contents of the waggons into barges lying in the dock, a ſtrong ſtage is erected on the wall, which projects over the water, and in order to turn waggons ſhort round and back them on to this ſtage, the rail-way paſſes over a large circular plate of caſt iron, which is ſuſpended on a pin beneath its centre; there being a circular ring under its circumference, which moves round freely, with a conſiderable number of ſmall wheels or rollers, whoſe axles are fixed therein, (ſee *figs.* 45 and 47, *Plate* VII.) upon another circular iron plate firmly fixed below; by this arrangement, it happens, that as ſoon as the fore and hind wheels of the waggon are advanced on to this circular plate, a very ſmall force applied to the waggon will turn it a quarter round, along with the plate and rails on which it reſts: the waggon is then run backwards off the plate, on the ſtage before mentioned, and its contents are ſhot into the barge below; it is then returned upon the plate, and the ſame is turned round until the rails thereon match the track, and the waggon can then move forwards, to make way for another loaded waggon, to be emptied in like manner, or it can be ſhoved backwards to a croſſing-place, as may be required. A ton weight or more in a waggon can eaſily be ſhoved along by a man, as he does a wheel-barrow. Rail-way branches are capable of being conducted into every foundery, or other great work near the line, to terminate under their large cranes for hoiſting goods, ſo that heavy articles can be loaded at once on to trucks for the rail-way. The branches of a rail-way admit of being multiplied almoſt without limit; farmers and others who have but an occaſional trade, may have their own waggons to be kept locked, and left for them by the ſide of the rail-way, one or more at a time, from the gang that is paſſing along the line. About November 1800, Dr. *Anderſon* recommended, in his *Recreations*, vol. iv. p. 204, the adoption of a double rail-way for heavy carriages between London and Bath; and about March 1802, Mr. *R. L. Edgeworth* recommended, in *Nicholſon's Journal*, 8vo. vol. i. p. 221, the experiment to be tried, on one of the great roads, for ten miles or more out of London, of a rail-way with four tracks, one for ſlow and another for faſt travelling carriages going each way, in order to avoid meeting or delay; theſe he propoſes to adapt to chaiſes and ſtage coaches, by means of low cradles or platforms, with wheels adapted to the rails, on to which a chaiſe, coach, or other carriage, could be drawn, and there confined, in order to be drawn along the rail-way; and which cradles the coaches might leave at any deſired point, to be drawn on the common road, which he propoſes to have by the ſide of his rail-ways. Dr. *Anderſon*, in the volume above quoted, recommends rail-ways to be made from the docks in the Iſle of Dogs, to different points in the environs of London; and he propoſes the bodies of theſe rail-way waggons to be moveable, and to be hoiſted off by cranes with their lading in them, and be placed on other, and larger wheels, with ſhafts adapted to the ſtreets; which, after delivering their lading, would return, perhaps laden with other goods, to the cranes to be replaced on the rail-way wheels. In vol. v. p. 291, of the doctor's work, it is recommended to uſe waggons on the propoſed rail-way with wheels large enough, and of a proper conſtruction, to be uſed in the ſtreet alſo. Wherever any conſiderable work is to be done, as in the excavation of the *London-Docks*, it has been found to anſwer, to lay down temporary rail-ways; and ſuch as admit of being moved as parts of the works become complete. For the uſe of mines, this facility of removal is often of conſequence, as the veins or pits wear out.

Doctor *Anderſon* obſerves, that 20 tons, in a barge upon a canal, will be drawn with eaſe by one horſe, travelling at the uſual rate that waggons move; and that on a rail-way the ſame horſe would, under favourable circumſtances, tranſport the ſame quantity of goods in a given time: but Mr. *Fulton* ſays, that five tons to a horſe is the average work on rail-ways, deſcending at the rate of three miles per hour; or one ton, upwards, with the ſame ſpeed. Mr. *Telford* obſerves, that on a rail-way well conſtructed, and laid with a declivity of 55 feet in a mile, one horſe will readily take down waggons containing 12 to 15 tons, and bring back the ſame waggons with four tons in them. Mr. *Joſeph Wilkes* in 1799 ſtated, that a horſe of the value of 20l. drew down the declivity of an iron road $\frac{5}{10}$ of an inch at a yard, 21 carriages or waggons, laden with coals and timber, weighing 35 tons, overcoming the *vis inertiæ* repeatedly with eaſe. The ſame horſe, up this declivity, drew five tons with eaſe. On another part of the road, where the acclivity was $1\frac{3}{4}$ of an inch at a yard, the ſame horſe drew down three tons; but it was neceſſary to ſlipper or lock the wheels here, to prevent his being overpowered by the deſcending weight. On a different rail-way, one horſe, value 30l. drew 21 waggons of 5 cwt. each, which, with their loading of coals, amounted to 43 tons 8 cwt. down the declivity of $\frac{1}{3}$ of an inch in a yard; and up the ſame place, he afterwards drew ſeven tons; the cwt. in all theſe experiments of Mr. *W.*'s being 120lb. In the ſummer of 1805 a trial was made on the *Surry* rail-way by Mr. Bankes, wherein a horſe, taken indiſcriminately out of a team, drew 16 waggons, weighing upwards of 55 tons, for more than ſix miles along a level or very ſlightly declining part of the rail-way.

Dr. *Anderſon* has calculated the expence of carrying goods in common waggons, or turnpike roads, a diſtance of eight miles, at 5s. 4d. per ton, and of carriage, the ſame diſtance, on a rail-way, at 4d. per ton, or only a tenth part of the former. *Recreations* iv. 208.

For ſteep deſcents, ſledges, or ſlippers of iron, muſt be provided, ſimilar to thoſe in common uſe with road-waggons, which can be placed under the wheels of the rail-way waggons, and hooked to the ſide of the waggon by a ſhort chain, in order to cauſe the wheel or wheels to ſlide upon the rails, whereby the tendency to deſcend may be checked.

Mr. *William Chapman* has, in his *Obſervations*, p. 42 and 54, recommended the uſe of waggons, that are to run on to the rail-ways that are to be prepared in the bottom of a flat-bottomed boat, inſtead of unloading the contents of the waggons into the boat; and when this boat with its waggons has arrived at its deſtination, the waggons are to be run out upon other rail-ways, to proceed forwards by land if neceſſary.

Mr. *Carr*, we are told, has introduced in the mines of Shropſhire, and other places, a ſlight kind of iron rail-ways, called train-roads, for the uſe of very ſmall waggons in their under-ground works.

Mr. *R. L. Edgeworth* has ſuggeſted (*Nicholſon's Journ.* 8vo. i. 223,) the uſe of light circulating chains running upon rollers, which are to be put in motion by ſmall ſteam engines placed at conſiderable diſtances; to theſe chains he propoſes carriages to be attached, for dragging them along upon rail-ways inſtead of uſing horſes. Since ſteam-engines have been brought into uſe, to work by the expanſive force of ſteam, and requiring no water for condenſation, a ſucceſsful trial of applying them to moving the trams on a tram-road has been made, *viz.* in February 1804, on the *Cardiff and Merthyr* rail-way, where 10 tons of iron (long weight) loaded on tram-waggons, with the additional weight of about 70 perſons for great part of the way, were drawn for nine miles upon the tram-road, at the rate of near five miles per hour, by the uſe of one of theſe ſteam-engines fixed on its own waggon made by Mr. Homfray, (for which engines Mr. *Trevethick* had previouſly taken out a patent, though it is perhaps an old invention) no ſupply of water for the boiler being found neceſſary in this diſtance.

The coſt of a ſingle rail-way, with croſſing-places, for a deſcending trade, was eſtimated by Mr. *Fulton*, who wrote in 1795, at about 1600l. per mile. Mr. *Wilkes*, in 1799, ſtated, that the expence of completing a mile of ſingle rail-way, where materials of all deſcriptions lay convenient, and where the land lies tolerably favourable for the deſcent, would be about 900l. or 1000l. fenced, &c. excluſive of bridges, culverts, or any extra expence in deep cutting or high embankments. Dr. *Anderſon* mentions, in 1800, the ſum of 1000l. per mile as the probable coſt of a double rail-way in the moſt favourable ſituations, and of very ſtout ones in the vicinity of London, where labour is dear, not leſs than 3000l. per mile; and Mr. *Wilkes* ſays, that wherever the quantity of goods to be conveyed on a rail-way, having a deſcent of not more than ½ an inch in a yard, amounts to two-thirds of downwards, and one-third of upwards loading; it is a doubt, if it will not, in that caſe, be a cheaper conveyance than by a canal, beſides the rail-way being more certain, where diſpatch is neceſſary, on account of froſt and dry ſeaſons. Another advantage attending rail-ways is, the greater certainty of the eſtimates for the ſame, when made with care and judgment, and the facility with which the whole work may, in general, be contracted for, to be completed at a ſtated time. The principal rail-ways which have been executed, are the *Cardiff and Merthyr*, the *Caermarthenſhire*, the *Sirhowy*, the *Surrey*, and the *Swanſey and Oyſtermouth*; and ſuch branches will be found to the *Aſhby de la Zouch*, *Cromford*, *Derby*, *Erewaſh*, *Lancaſter*, *Leeds and Liverpool*, *Peak Foreſt*, *Shropſhire*, *Somerſet Coal*, *Trent and Merſey*, and ſeveral others, to which number almoſt every day is adding.

The *conſtructing of Bridges* for croſſing canals and navigable rivers, often occaſion a very ſerious part of their whole expence, and this circumſtance occaſioned the attempt in ſome of the earlier canals, to ſubſtitute paved *fords* in many inſtances; Mr. *James Brindley* propoſed theſe at firſt, for ſome places on the *Trent and Merſey* canal; and on the canal which Mr. *Davis Dukart* conſtructed to the Tyrone collieries in Ireland, theſe were ſubſtituted in place of bridges. Mr *Fulton* has recommended the general adoption of fords on his ſmall canals, but Mr. *Chapman* obſerves, that the water in ſuch caſes muſt not exceed two feet nine inches in depth, as otherwiſe hay, ſheaves of corn, &c. in common carts would be liable to get wet in croſſing. On the China canals we read, that there are elliptical arches of ſtone over their canals, the longer axis being vertical, and high enough for the maſts of their veſſels; theſe bridges being only intended for foot paſſengers, and are aſcended and deſcended by ſteps. On our canals, bridges for foot paſſengers only are generally conſtructed of wood, and are mounted by ſteps, as at Paddington on the *Grand Junction*. In all large and important bridges the arches ſhould undoubtedly be ſo formed that the materials thereof are in equilibrium, independent of the cement that may be uſed between the ſtones or bricks; the principles of which arches will be found in our articles ARCH and BRIDGE; but for the common bridges for croſſing of canals, which are wanted in ſuch great numbers, flat ſemi-elliptical arches have been, in general, adopted, on account of ſuch giving width for the canal and towing-path underneath, without raiſing the top any unneceſſary height, which ſo enhances the expence of landing up, or forming the ſlopes to the bridge. From the habits which neceſſity has in a great meaſure introduced with canal bridge-makers, of uſing only the beſt materials, performing the work with great care, and not ſtriking their centres too ſoon, ſuch bridges are found to ſtand tolerably well, although very far removed from an equilibration figure; yet inſtances are not wanting on moſt canals of their ſettling, and even falling down in ſome caſes. A kind of brick bridges have long ſince come into almoſt general uſe on canals, of which we have given a plan, ſection, and perſpective view. See CANALS, *Plate* IV. *figs.* 40, 41, and 42. The form of theſe bridges is well calculated for ſaving of materials, and giving ſtrength at the ſame time, the whole of the walls being more or leſs battering, and the ſide walls are ſplaying outwards at their ends, to make the entrance on to the bridge the more eaſy, by which the ſide walls are rendered curving inwards in every part. In the building of bridges the utmoſt care muſt be taken to ſink the foundations down to ſound ſtuff, or to drive piles on which to begin the work; it is a good practice to have wedge-like or arching bricks made, on purpoſe to uſe after a certain number of courſes of key bricks, or thoſe forming the ſofits of the arch, and to introduce oblique courſes of bricks for the more effectual tying of the work together, as we have mentioned in ſpeaking of tunnels. Large bricks made of the beſt earth and well burnt, ſhould alſo be uſed, placed on edge upon the top of the walls of the bridges, as a coping, unleſs very good ſtone is near at hand, the top corners of the coping bricks or ſtones ſhould be carefully rounded off in the making, in order that the ſame may preſent as few angles as poſſible for the weather or the traffic to catch hold of.

We have before mentioned the care which ought to be taken in every inſtance, to find ſtuff with the leaſt poſſible expence of moving it, for landing up the bridges; from theſe having, in ſome inſtances, been left too ſteep for the convenient and ſafe uſe of the public; it has not been uncommon, in later acts, to make proviſions on theſe ſubjects; on the *Grand Weſtern* it is enacted, that the aſcents to the bridges ſhall not exceed 2½ inches in a yard, and on the *Wilts and Berks* this riſe is limited to 3 inches in the yard at the moſt. The width of the carriage-way, on the bridge, in the narroweſt places, is alſo fixed in ſome acts, wherein we have ſeen 12 feet mentioned as a limit in ſome caſes. We have before obſerved, that the canal ought, if practicable, to be conducted into deepiſh cutting, wherever a brick or ſtone bridge is to be erected, in order that the ſtuff may be thereby procured, for landing up each ſide of the bridge, and that the abutments of the bridge may be the more ſolid, and the foundations more likely to reach ſound ſtuff, without an extra depth of walling, or the neceſſity of piling for ſuch purpoſe. On this account it is, that the tail of a lock generally preſents a proper place for a bridge, and where the walling, which muſt have been made for wing-walls, below the lower lock-gates, is avoided, or turned to account in the bridge. In places, where from the great traffic that is to be expected, or other cauſe, a towing-path will be wanted on both ſides of the canal, the bridges ſhould be made on a ſcale large enough to admit of a towing-path on both ſides under the bridge, as in the two or three bridges neareſt to Paddington baſon, on the *Grand Junction*.

For *occupation*, or accommodation bridges, and even on ſome public roads, as on the *Sankey* canal, and others, a kind of ſwing or ſwivel bridge has in general been adopted, of which ſome mention has been made under our article BRIDGE. See *fig.* 43 *Canals*, *Plate* VII. A flat platform of wood ſtrongly framed together, covered with planks, and having ſide rails, is prepared, wide enough for the purpoſes of a bridge, and about half as long again as the canal is wide, in the contracted walled part intended for the ſwing bridge. One end of the platform for this bridge is framed as light as can be conſiſtent with ſtrength, and the other very heavy, with proviſion for ſtowing large ſtones or pigs of caſt iron therein, ſo that the ſame will reſt in equilibrio on a point at about one-fifth of its length from the heavy end; under this point, a large circular plate or ring of caſt iron is fixed, having a ſmooth circular hollow ſunk therein. An exactly ſimilar plate is embedded, and firmly fixed on the ſolid wall at the ſide of the canal, except that this laſt has a ſtrong iron centre or point ſtanding up, to enter a hole ſunk in the upper plate to receive it. On this pin the bridge is ſuſpended in equilibrio, and in order that no impediment may ariſe to turning the bridge round, when its balance is by any circumſtance deſtroyed, a number of ſmooth caſt iron balls, of two and a half or three inches diameter, are placed in the circular groove or hollow ring in the two plates, which act effectually as rollers for leſſening the friction between the circular plates, in turning the bridge on and off the canal; or, a ring containing ſeveral rollers (*fig.* 45 and 47), is ſubſtituted inſtead of the iron balls above-mentioned, between the lower and upper plates *figs.* 44 and 46. A receſs is formed on the bank juſt to receive the bridge, when a boat is to paſs, and when the bridge is turned acroſs the canal, each end of the bridge (which ends are rounded into circular arcs, ſtruck from the centre pin), ſlides on to a ſimilar circular receſs in the road, with a firm bearing at a very ſmall diſtance below the ends of the bridge, when it is in equilibrium, on the centre pin and balls or rollers; by this arrangement it happens, that the heavieſt loaded carriage croſſing the bridge, is not able to depreſs either end of the bridge on which it paſſes, in any ſenſible degree. The engineer ſhould carefully avoid the uſe of theſe ſwing, or indeed of any moveable bridge, where the towing-path is to change from one ſide of the canal to the other, becauſe the bridge muſt remain acroſs the canal until a barge in paſſing, is got near enough for the towing-horſe to croſs over the bridge, and the bridge muſt then be turned off the canal before the boat can paſs, and it continually happens, unleſs the towing-line is of great length, or is caſt off at ſome diſtance before the boat arrives at the bridge, or the greateſt dexterity is uſed, that the boat ſtrikes the bridge before it can be turned off the canal into its receſs: where ſeveral boats are cloſely following each other, there difficulties are much increaſed, and great delay muſt take place, or the bridge will ſoon be knocked to pieces. Swivel or turn bridges have ſometimes been erected on the towing-path ſide, but they form there a moſt ſerious obſtacle to the towing of boats; and on that account are generally placed on the off bank, and as no methods have hitherto been brought into general uſe, of turning on or ſhutting ſuch bridges for perſons to paſs over them, except the perſons, or ſome others, are at the time, on the ſame bank of the canal on which the bridge ſtands, in order to turn it over the canal; this has occaſioned the neceſſity of clauſes in every act, or ſet of bye-laws, requiring boat-men always to ſhut to every ſwing-bridge, or draw-bridge, as ſoon as their boat has paſſed. The great loſs of time and labour in thus continually turning the bridges on and off, the wear that ſuch continual uſe occaſions, and the frequent damage which ſuch bridges ſuſtain from boats ſtriking againſt them, if, by the leaſt delay of the boat-men or accident, they are not turned off before the boat gets up; have occaſioned our thinking a good deal on the ſubject, in hopes of deviſing ſome method of turning the bridge on when wanted, from either ſide of the canal; becauſe ſuch a contrivance would authoriſe the alteration of the preſent regulations, and require each ſwing-bridge to be left open, and out of the way of the navigation, except during the time that it was actually in uſe, by perſons or carriages paſſing over it: another material evil would thereby alſo be remedied, that is, the difficulty which now exiſts of preventing the farmers' cattle, in the fields on the off ſide of the canal, from paſſing over the bridges, and eſcaping along the towing-path, without an expenſive circle of fencing and a gate to ſeparate the bridges from the fields, for no gate or obſtacle can conveniently be made on the towing-path ſide to obſtruct their paſſage. Chains and pulleys under the canal, and motion conveyed upon *Bramah*'s patent principle, in pipes under the ſame, were conſidered among others, as the means of turning the bridge on, when wanted; but, our ſpeculations hereon were, happily, at the moment of writing this (October 1805,) interrupted by the information of a method, which was ſucceſsfully brought into practice very lately, by Mr. *Benjamin Bevan*, the engineer upon the middle diſtrict of the *Grand Junction* canal, *viz.* near the ſteam-engine on the Wendover branch, where a ſwing-bridge of the common conſtruction, with a railing or fence on each ſide of it, has an addition made to it, on the ſide that is next the canal when the bridge is open, or in its receſs, at about three-fourths of its length, from the centre pin on which the whole turns; this conſiſts of a jib like that of a crane, or the bars that are ſometimes uſed for ſtopping carriages at the ends of ſtreets: an upright piece of wood is hung by two hooks and thimbles, like thoſe of a common gate, to the ſtandard or upright on the ſide of the bridge; to the top of this a rail of 4 or 5 feet long is fixed horizontally, ſupported by a brace underneath, from near the bottom of the upright piece; on the top of the horizontal piece are two ſtrong ſtaples fixed, adapted to receive the thickeſt end of a very ſlender and light pole, ſuch as are uſed for the handles of hay-rakes, but they muſt be longer, and rather larger for wide canals; a nail drove in between the ſtaples through the pole fixes the ſame, and makes it form a light and eaſily renewable continuation of the top rail quite acroſs the canal, ſo that a perſon, wanting to croſs the bridge from the towing-path, can take hold of the end of the pole and pull by the ſame, and thereby turn the bridge over the canal; or, if a perſon has croſſed the bridge towards the towing-path, he can with equal facility take hold of the end of the pole and ſhove the bridge round to the other ſide. The hinges of the jib that carry the pole are ſo adapted, that the pole has a tendency to hang directly acroſs the canal, to the moſt convenient point for being taken hold of; but, at the ſame time it is with the leaſt force turned round on its hinges until it is brought along-ſide of the bridge, and quite out of the way of boats that are paſſing. This very ſimple and cheap apparatus, we are told, anſwers effectually; no impediment is offered to the horſe or towing-line; but when a boat arrives, whatever part thereof ſtrikes againſt the pole, it recedes and ſuffers the boat to paſs, and then by its own weight reſumes its ſituation acroſs the canal, ready for turning the bridge. The ſolid part of the jib is not made long enough to be liable to be ſtruck by the boat, or a man ſtanding thereon; and poles in plenty, of the proper ſize and length, can be in readineſs, for replacing in a minute any pole which is worn out or broken by accident.

Bridges which have no towing path under them, preſent a great obſtacle to towing, becauſe the line muſt in thoſe caſes be caſt off from the barge; except, occupation bridges, like the wooden one at Rotterdam in Holland, could be introduced, where the bridge, we are told, conſiſts of two ſeparate ſegments, each ſupported firmly on its own bank, and leaving a ſlit quite acroſs the bridge for the towing-maſt to paſs through, and thus they avoid caſting off of the line: this ſlit need not be ſo wide but that foot paſſengers can with eaſe and ſafety ſtep acroſs it; and, on the paſſage of horſes or carriages, a moveable flap turning quite flat back upon hinges, might be turned over to complete the road.

Where ſwivel bridges of great width and ſtrength are required, and need but ſeldom to be turned off, as for admitting ſhips at high water to the *Weſt India* and *London Docks*, double wooden or caſt iron ſwivel bridges are in uſe, with a moveable frame under each part, conſtituting parts of the ribs of the bridge, which frames turn on a hinge or joint, and are taken up or ſuſpended by a ſcrew at the other end, to clear the walls of the bridge when the ſame is to be turned off; and which, when the bridges are turned over to meet in the middle, can be let down by turning a winch, ſo as to fall in ſtrong grooves prepared in the copings of the walls, and complete the abutments of the ribs of the bridge, as ſtrongly almoſt as a fixed wooden or iron bridge could be made; an excellent example of which may be ſeen in Wapping ſtreet, croſſing the entrance to the *London Docks*, as mentioned under the article Bridge. It appears that Mr. *H. Shadwell* was rewarded for ſome improvements to ſwivel-bridges which he ſuggeſted to the *Society of Arts*. See their *Tranſactions*, vol. xiii. page 227.

*Draw-Bridges* are not uncommon as accommodation bridges on ſome canals; the frame or platform of them, with their ſide rails attached, is moveable on ſtrong hinges upon the top of the wall or one ſide of the canal, and when down ſhuts into a groove prepared on the oppoſite wall, ſo as to preſent no projection or obſtacle to the road over it. For raiſing theſe bridges, two ſtrong and tall poſts are fixed upright on the bank of the canal a little behind the hinges of the bridge; on the top of theſe poſts are two very long and tapering pieces of timber called balance-beams, which turn on a hinge near their middle, their ſmall ends being connected by chains to the further end of the bridge, to which the thick ends of the balance-beams are made to be a counterpoiſe, by means of lead or iron nailed on to the ſame if neceſſary: when the bridge is ſhut, or prepared for paſſing over, the balance-beams reſt nearly horizontal, there being a chain attached to the thick end of each, which hang down and can be reached by a man or boy, and by pulling at which, he can rear the bridge up upon its hinges for boats or veſſels to paſs. For croſſing the Docks in Liverpool in different places, very large draw-bridges are in uſe, ſuppoſed to be the largeſt in England. But we are informed by Mr. Rennie, an engineer of the firſt eminence, that he has ſeen much larger draw-bridges in France. On the *Forth and Clyde* canal the draw-bridges are double, meeting in the middle of the canal when ſhut down. It appears that the Chineſe have a ſort of draw, or rather ſliding bridges over the piers of the flood-gates of their canals, which, to prevent interruption to the maſts of veſſels, are conſtructed ſo as to be eaſily withdrawn when veſſels are about to paſs; they are flat wooden bridges, narrow and light, reſting on rollers fixed in their frame, and running on a couple of looſe ſpars that are withdrawn after the bridge. Wooden bridges are very often wanted for carrying the towing-path over the entrances to docks, or the ſide branches of a canal, and from their great ſpan, to avoid a narrow place at the turning; theſe are often attended with conſiderable expence; they ſhould be conſtructed of very ſound and durable timber, well truſſed, and as light as is conſiſtent with ſtrength, as they are ſeldom made wide enough to be uſed except by men and horſes. We cannot too often adviſe that bridges of wood or iron, and ſtone ones alſo of large ſpan, ſhould be wider at the abutments, and diminiſh by a proper curvature of the ſides to the middle, to prevent the ſtrain of the materials on a ſudden lateral impulſe, from cauſing them to give way and cripple ſideways.

The ingenuity and enterpriſe of Britiſh artiſts have given riſe within the laſt 30 years to an improvement of the firſt importance to river navigation, by the introduction of caſt iron bridges of great ſpan and height, by the adoption of which, in favourable ſituations, ſhips may be admitted farther up into our large rivers; and in almoſt every caſe, the impediments to navigation may be removed that are occaſioned by the narrowneſs and lowneſs of the arches of our old ſtone bridges, which not only exclude or interrupt the towing-path and neceſſitate barges to lower their maſts, but in general cauſe ſuch a fall in the water, owing to the deficiency of their water-way, as to be dangerous and impaſſable at particular ſtates of the river. Near Coalbrook-dale on the *Severn* river this improvement was firſt carried into effect. particularly deſcribed in our article Bridge. A perfect model of this bridge, which is 100½ feet ſpan and 45 high within the arch, was prepared by Mr. *Abraham Darby*, who caſt the ſame, and preſented to the *Society of Arts*, in whoſe collection it may be ſeen by any one who applies in the Adelphi: ſee their *Tranſactions*, vol. vi. pages 228 and 232. Buildwas bridge of iron over the *Severn*, within two miles of the former, we have already deſcribed in the article referred to, and have only to add, that Mr. *Thomas Telford*, the engineer of this bridge, has given a plate of the ſame in *Plymley's Agricultural Report of Shropſhire*, page 316. For the principles on which the Wearmouth bridge, which we have deſcribed, is formed, Mr. *Rowland Burdon* on the 18th September 1795 took out a patent, which ſee in the *Repertory*, vol. v. page 361, where a view of this very curious ſtructure will alſo be found. We are ſorry to add that we heard lately in converſation, that this bridge has ſhewn ſymptoms of twiſting or giving way ſide-ways, which have greatly alarmed ſome perſons for its ſafety. The caſt iron bridges at Bridgewater on the *Parret* river, and at Staines on the *Thames*, have been mentioned in our article referred to above; the latter, owing to the miſtaken economy of the truſtees, in having vaults made in the abutments, which ought to have been of ſolid maſonry, gave way, and has been entirely taken down, as the new ſtone bridge erected before it, was obliged to be from the ſame cauſe. We cannot enough admire the prudent precautions of the ſelect committee of the Houſe of Commons in 1800, who inveſtigated the different propoſals for rebuilding of London bridge. (See *Tilloch's Philoſophical Mag.* vol. x. page 13.) They conſulted the opinions of the moſt eminent profeſſional men, and had a very accurate ſet of models, conſtructed in braſs by Mr. *Berge*, the ſucceſſor to the celebrated *Ramſden*, under the direction of Mr. *Atwood*, for illuſtrating the nature and properties of equilibrium arches. One of the deſigns which were preſented to this committee, and which has ſince been engraved by Mr. *Wilſon Lowry* and publiſhed, is that of Meſſrs. *Telford and Douglas*, for a ſingle arch of caſt iron of 600 feet ſpan, and riſing 65 feet above high-water mark: as this ſcheme has not yet, nor ever may be carried into execution, it would be ſwelling the preſent article too much to detail the excellent proviſions which the contrivers had made, for the execution and ſtability of this grand work. We proceed, therefore, to mention, that Mr. *Fulton*, in his treatiſe ſo often before quoted, has given deſigns (plates 14, 15, and 16), and explained the principles, page 120, of different bridges of caſt iron. On the 24th May 1796, Mr. *James Jordan* took out a patent for conſtructing bridges which ſhould be ſuſpended from ribs of iron above: ſee *Repertory*, vol. vi. page 220, and on the 7th February 1797, Mr. *John Naſh* obtained a patent for a method of conſtructing bridges of hollow quoins of iron, that can be filled with maſonry or other ſolid matters after the bridge is put together; the piers of bridges he propoſes in like manner to conſtruct of hollow caſes of iron, to be filled with maſonry after they are brought to their proper places: ſee *Repertory*, vol. vi. page 361. Of wooden bridges for large and navigable rivers, we have given an example in the once juſtly famous Schaffhauſen bridge over the *Rhine*, in our article Bridge. Mr. *Fulton* mentions a very famous one at *Wettingen* in Switzerland; and has given us deſigns for bridges for newly ſettled and woody countries, wherein large timbers dowelled together, ſupply the place of key-ſtone, above which the platform for the road is to be ſupported. The ſame gentleman has propoſed in conſtructing the above kind, or iron bridges that are very flat and low, to obtain the neceſſary ſtability of the butments, by continuing the line of key-timbers or ribs with their proper curvature for ſome diſtance into the bank on each ſide. We have before ſpoken, under the article Bridge, of the proper form of the projecting angles of the piers of a bridge, and ſhewn that for navigable rivers, ſharp corners ſhould be avoided, from the damage that ſuch might do to the boats and veſſels.

Bridges will be wanted in the conſtruction of rail-ways for carrying the rail-road over rivers, ſudden valleys or roads; ſome of theſe may require caſt-iron arches; ſome of them muſt be of ſtone or brick; but oftener, ſuch may with propriety be conſtructed of wood, taking care that they are effectually truſſed, or formed on the beſt principles, alſo that the joints are effectually ſecured from wet, and the whole covered with a coating of mineral tar or paint, to be renewed from time to time to keep out the weather. One other thing remains to be mentioned reſpecting bridges, i. e. owing to the contraction of the canal and curvature of the towing-path at a bridge, the towing lines are apt to fret and wear away the corners of the bridges, occaſioning alſo a great waſte in ropes: for remedying this, light hollow cylinders of wood are placed upright, or nearly ſo, according as the wall is upright or battering, at all the corners of the bridges or other obſtructions to the direct line of the towing-path; theſe cylinders being hung on centres or pivots, at top and bottom, they turn round by the action of the rope, and prevent friction and wear.

The *Towing-Path*, horſe-path, or hauling-way of a canal, ſhould always be on the lower ſide if practicable, the traffic on the ſame having a tendency to conſolidate the new made bank, to prevent the accumulation of weeds and the harbour of vermine, that by lodging in and perforating the bank might endanger the ſame. The towing-path ſhould change as little as poſſible from one ſide of the canal to the other, and when this is unavoidable, it ſhould be always done at ſome fixed bridge, to avoid the inconveniencies before pointed out; the change ought never to be made in deep-cutting, as has been done near Tring on the *Grand Junction*. The towing-path ought never to be interrupted if the ſame can be avoided; and, beſides having a way under all bridges (except thoſe where a change of ſides is to be made) we hope to ſee the example followed, which has been ſet at Atcham on the *Shrewſbury*, and Newbold on the *Oxford* canals, of continuing the towing-path through the tunnels, wherever the ſame ſhall appear practicable. On the propoſed *Bude and Launceſton* canal, it was intended to form a towing-path on both ſides; a hint that may prove very uſeful in ſome ſituations of greater traffic, than there ever was likely to be on this canal. It is often provided in the act, that the towing-path may be uſed by the owners and occupiers of land on the line as a bridle-way, or as a drift-way for their cattle; as on the *Aſhby de la Zouch*, *Grantham*, *Leiceſterſhire and Northamptonſhire Union*, *Oakham*, &c. Frequently, permiſſion is given to perſons to uſe the towing-path as a foot-path or bridle-road, and we think it would in ſome inſtances be proper to obtain the power of levying a ſmall toll on horſe paſſengers; if the company ſhould at any future time ſee it right by public notice to permit their towing-path to be ſo uſed. It ſeems inapplicable to the purpoſe of a towing-path, to make public drift-ways of them in any caſe, on account of the damage which looſe cattle would do to the banks and fences, and the impediments which droves of cattle would preſent to the hauling-horſes and lines. In forming the towing-path, care muſt be taken to make the ground ſound, and to cover it with a proper thickneſs of good gravel; and we cannot but recommend the raking or ſorting of this as it is laid on, throwing the large or irregular ſtones forward to be covered with better gravel, ſo that the ſurface may be ſmooth and even, without rough and large ſtones to throw the horſes down, and render the uſe of the path unpleaſant. On the duke of *Bridgewater*'s canal, where proper materials for road-making are very ſcarce, the ſhale and ſlates, or refuſe coals from the mines are brought out and calcined, or burnt in very large heaps, the cinders of which are uſed for making and repairing the towing-paths upon his canal. The height of the towing-path ought not to be leſs than one foot, or more than two or three feet above the ſurface of the water, or top-water line.

The *fencing* of the ſides of a canal is a buſineſs deſerving of more attention than has been uſually paid to the ſame. Quick-ſet or other live fences ought by all means to be made, except in the caſe of a rocky country, where good and durable walls can be built at an eaſy expence: rail or pale fences are very improper, except in and near towns, on account of their heavy expence in repairs. The continual weeding which quick-fences require, the great injury which the plants ſuſtain from weeds, if the ſame are at any time ſuffered to grow up, and the damage which the pulling or hoeing up of weeds ſo repeatedly, do, in wearing away the ſoil, and more or leſs expoſing the roots of the quicks, and beſides theſe, the plants being often wounded in their tender bark by the hoes uſed by the weeders, are moſt ſerious difficulties in the raiſing of quick-fences, wherever our experience has extended, except in the north-eaſtern parts of Norfolk, where the ſpirited and intelligent tenants, that there abound, have a method of raiſing fences, which they are continually doing during the currency of their leaſes, that we are happy, in this inſtance, of being able to mention, becauſe it has not yet, we believe, appeared in print. The line of an intended hedge and ditch being marked out, the firſt ſtep is to collect carefully all the top-ſoil or vegetable mould into a ridge where the centre of the bank is to be, and if this vegetable mould proves too abundant, the extra quantity is thrown into heaps further off, in order to be mixed with dung, or carted to ſome parts of the land, which wants a greater ſtaple of mould. This done, a row of ſpits or lumps of earth out of the ditch are laid carefully in the front of the bank, and on theſe, when reduced to a regular line by paring with the ſpade, the white-thorn ſets are placed a little inclining upwards, at about four or ſix inches apart; care is taken in laying in the ſets, that their roots are bedded in the vegetable mould, that is to form the centre of the bank; when this is done, another row of ſpits or lumps is dug out of the bottom of the ditch, and laid upon the quicks, which being patted down and levelled at top with the ſpade as before; another row of quick-ſets is laid in, taking care that each plant in the upper row is over a ſpace in the lower one, and that their roots are incloſed in the top-ſoil. Other ſods are then dug out of the ditch and piled up, with the proper ſlope or batter, until the bank is raiſed to the intended height; the vegetable mould is then dreſſed up into a regular bank at the back, and the remainder of the ſtuff from the ditch is thrown over, and is afterwards carefully ſpread and laid up againſt the back of the bank, ſo as entirely to encloſe the vegetable ſoil in a caſe of dead earth, or ſtuff taken from below, where cultivation has depoſited the ſeeds, or nature the viviparous roots of ſuch plants. Still further to accompliſh this excluſion of the ſoil in the bank, from the action of the ſun, air, and other ſtimulants to vegetation, at a proper ſeaſon in the ſpring, a quantity of dead earth is pared up from the bottom of the ditch, and worked and chopped about, until it is in the ſtate of *puddle*, before deſcribed. The tops of the quicks are cut off nearly even with the ground, after which, a labourer carefully plaſters every part of the face of the bank with this prepared or puddle-like ſtuff; and after it is laid on, having a pail-full of water at hand, to wet his ſpade in if neceſſary, he works this plaſter about, giving the flat ſurface of his ſpade exactly the circular and plaſtering motions that plaſterers uſe when at work on a ceiling or wall. If it ſhould appear that froſts have mouldered down, or injured the facing of the bank, the ſame is carefully repaired and worked again, as above, before the ſeaſon for the vegetation of the quicks. As ſoon as the white-thorns have put forth their leaves in the ſpring, a careful labourer walks along the ditch, with a knife in his hand, and wherever a plant is miſſing, from among thoſe which have ſhot forth, he digs in the point of his knife with care, to find and releaſe the top of the ſet, which otherwiſe might be ſmothered and confined by the plaſtering of the bank. The benefit of this procedure is inconceivably great, in almoſt totally preventing the growth of weeds, and in confining the moiſture in the vegetable mould from eſcaping in dry ſeaſons. At a time in the ſummer, when every part of the ſurface was covered with vegetation, we have with pleaſure examined ſome miles in length of quicks treated in this manner, and although the quicks had made the fineſt ſhoots which could be imagined, not a veſtige of vegetation of any kind beſides was to be found on the bank; and thus, with proper care in renewing the plaſtering or working of the bank, many of them remain until the quick is grown up to be a fence; and it is almoſt literally true, that weeding is here unneceſſary, although no ſoil can be more congenial to, or worſe ſtored with the ſeeds of annual weeds, than ſome of thoſe were of which we have been ſpeaking. The ditches are made deep, and the ſides of them as ſteep as the ſoil will ſtand in the general, ſo that dead or guard fences are generally omitted on that ſide; and ſo they are often on the other, or back ſide, and a prick-hedge is ſubſtituted, which, with care, and the letting of ſheep only looſe in ſuch fields, anſwers the purpoſe very well. Some time before the bank is made up to the intended height, the labourer goes along upon the top of it, ſhovels off the looſe top, and treads down the top of the bank ſo as to form a flat of perhaps 12 or 14 inches wide; into the centre of this he ſtrikes in his ſpade, and gives the ſame a lunging motion, ſo as to open a narrow and deep notch; this operation he repeats, until a notch of this ſort is opened the whole length of the bank; he then proceeds to ſtick this with ſhort and rough buſhes, ſo cloſe as to make a complete hedge; he then throws up out of the ditch as much ſtuff againſt the buſhes as will lay on the plane or top, in which the hedge is ſtruck, and beats the ſame down ſtrongly with his ſpade; the ſame proceſs is followed at the back of the hedge, by which theſe buſhes are ſo ſecurely ſet into the bank, that they will often ſtand until the quick is become a fence; in places where the deſtructive pilfering of the poor is properly repreſſed. Some may perhaps conſider us as going here too far into the ſubject of fencing, but we requeſt of ſuch to conſider how important the ſubject is to a canal-company, which may have to raiſe much more than a hundred miles in length of quick-fences, as was the caſe a few years ago with the *Grand Junction* canal company, and ſome others, ſome of whom are ſtill feeling the very heavy burden of weeding their quicks two, three, or four times annually; which an adoption of the above principles would, we are certain, have tended to reduce moſt materially. See our articles INCLOSING, FENCING, &c.

The quick for a canal ought to be placed a little above the level of the towing-path, and be ſeparated therefrom by a ſmall ditch, to prevent the towing-horſes from biting or trampling on the quick; but the principal ditch, where the ſudden falling away of the off-bank does not anſwer the ſame purpoſe, ought invariably to be on the field ſide, for keeping the farmers' cattle at a proper diſtance from the quick, and to check their attempts at jumping through or over it. The quick ought not to be placed too near the towing-path, and the hedges ſhould be carefully cut and plaſhed about every twelfth year, both to preſerve them vigorous and in good growth, and alſo to preſerve the towing path clear. On the *Oxford* canal, near Braunſton, we remember that the hedges were ſo grown over the towing-path, in the year 1799, that it was quite dangerous riding along, and the horſes were driven ſo near the edge of the canal, by the intruſion of the buſhes on the path, that the bank was ſuffering materially. In places where the canal is embanked, it will be proper to place the hedge at the bottom of the ſlope, in order to enable the company the better to prevent the growth of rank and large weeds, and the conſequent harbouring of vermin, which would lodge in the bank: ſteep embankments might alſo be materially damaged by the treading of cattle on their ſides. Through common fields, or very large paſtures, it is ſometimes not neceſſary to fence off the towing-path therefrom, but at the boundaries or entry to ſuch fields, a gate is placed in the towing-path, to prevent the intermixture or eſcape of the cattle; and generally theſe gates are double, falling rather forcibly towards each other, by which conſtruction the cattle are prevented from puſhing, or the wind from blowing open the gates, as would otherwiſe often happen.

At the termination of every principal eſtate or farm that adjoins the towing-path, it is uſual to place a ſwing gate acroſs the ſame, to prevent cattle getting away, in caſe they ſhould break, or by accident get into the towing-path. Cylinders ſhould be placed, as before deſcribed, againſt each of theſe gates for the towing-line to run upon; and ſide rails ſhould be placed inclining up to the top of the poſts, to aſſiſt the rope in getting over the ſame.

*Draining* is another expenſive buſineſs, of which a canal company will have a good deal to perform, in moſt caſes. Soon after a canal is filled with water, and often ſooner on the upper ſide, owing to the courſe of the land-ſprings, and thoſe of a more permanent character being intercepted by the puddle-ditches, wet places will appear on the land, which would, if neglected, become unfit for cultivation; theſe are often of conſiderable extent below the canal; and the committee of the canal company muſt not be ſurprized at hearing the farmers attribute many wet places in ſuch ſituations, to the ſoakage of their canal, that really are not affected thereby. It would be of uſe, and the ſource of much ſatisfaction, if the reſident engineer were to note down in his book all the wet and ſpringy places that appeared on the ſloping land, below the level of the canal for a conſiderable diſtance, and the condition or run of water from each before the canal was made; becauſe the appearance of new queaches, as the farmers in many parts call them, or the increaſe or enlargement of others, is often the firſt and only indication of an increaſing and hurtful leak from the canal. The committee ſhould not be nice in drawing the line, as to the extent of draining which they order to be done; but it would, on the contrary, be highly to the credit of their concern, and the intereſt of future canal ſchemes, to bear the whole or a portion of the expence of effectually draining all the land, whoſe wetneſs could, even in miſtaken prejudice, be aſcribed to their canal. The execution of theſe operations ought not to be confined to the quackery of boring a hole here and there in a trench, without any theory or meaning; but the reſident engineer, or ſome profeſſional man employed expreſsly for the purpoſe, ſhould, by a judicious application of his experience and knowledge of the *ſtrata* in every place, apply that particular method of draining, as to the ſituation and depth of the drains, &c. which every ſpot may require. And theſe operations are more various and important than what any perſon, who has not made the ſubject his particular ſtudy, can poſſibly be aware of. See our article Draining. There is a danger attending drains made near a canal, from rats or moles working their way unobſerved beneath the ſurface, between the drain and the canal; for detecting which, or other leaks, it will be proper for the reſident engineer to enter in his book a minute deſcription of the ſituation of the mouth or vent of every drain, chooſing ſituations for the ſame, when they are made, in ditches, where they can be readily got at, and not be liable to be damaged by time, or the treading of cattle. The length and direction of every branch of under-drain which vents at that mouth, ſhould be noted down, and the quantity of water which the drain diſcharges ſhould alſo be carefully eſtimated, at ſome ſhort diſtance of time after the ſame is finiſhed; and a regular and periodical inſpection of theſe drain-mouths by the engineer with his book in his hand ſhould be made, by which any ſecret leak could hardly fail of being detected. It is almoſt unneceſſary to point out the importance of an attention to theſe circumſtances, in ſituations where water is very ſcarce.

The *conſtruction of Boats* for canals and rivers requires ſome notice in this place. Mr. *Chapman*, who has given ſome excellent directions reſpecting the form of boats leaſt liable to overſet or be injured by heeling, has very properly obſerved (*Obſervations*, p. 102.), that the area of a croſs ſection, of a boat to be uſed on a canal, ought not to approach ſo near to the area of a croſs ſection of the water in the canal as 1 to 3, or conſiderable inconvenience will ariſe, both from the increaſed reſiſtance of the boat, and the damage to the banks, from the counter current to fill up the ſpace the boat leaves in her rear. This circumſtance requires particular attention, particularly in boats that are to move quick, like the paſſage-boats from Mancheſter and Paddington, on *Bridgewater*'s and the *Grand Junction* canals: in the former of theſe, we obſerved a conſtant elevation of the water before the paſſage boat, as it moved along, of at leaſt 9 inches, and perhaps more than a foot at times; and the rapidity with which the water ran backwards, between the boat and the ſides of the canal, appeared to have a moſt deſtructive effect upon the latter, particularly on the towing-path ſide; and often this was laid quite under water, for conſiderable diſtances together, by the ſurge or wave oppoſite to the head of the boat as it paſſed along: while the labour of towing was moſt materially increaſed. We regret that we had not the means of aſcertaining, how much the head of the boat was elevated upon this artificial wave in the general, and up which inclination the towing mules were conſtantly drawing it. Some attention ought to be paid to the form of the head and forepart of the boat, with a view to its letting the water paſs freely off by its ſide: flat headed boats, and thoſe whoſe ends are rectangular in particular, ought not to be towed faſt, or great loſs of labour and damage to the banks will be the conſequence, unleſs the canal is very wide and deep. It has been propoſed to form boats ſharp at one end and flat at the other, ſo that the flat ends being joined, two of them may form a body, diminiſhing properly at each end, for eaſy paſſage through the water, and for ſteerage. Mr. *Nicholas King*, an American, has propoſed boats in four parts, that can be detached when the ſame are to paſs an inclined plane, and be afterwards rejoined. Since the uſe of caſt-iron has become ſo general, Mr. *John Wilkinſon* has conſtructed boats and barges of iron, ſome of which are uſed on the *Severn* river, and others upon the different canals in Staffordſhire, Worceſterſhire, &c. Mr. *Robert Fulton*, in his *Treatiſe*, p. 31, has propoſed and deſcribed a kind of rectangular boxes, with low wheels (or rather trucks, as the axle and them are to be caſt in one piece) fixed under their bottoms, to be uſed upon canals inſtead of boats, on account of the uſe which he propoſes to make of them, upon inclined planes and rail-ways, as well as on the water, as we have before mentioned. Mr. *William Chapman*, who has examined this ſyſtem particularly, in his *Obſervations*, has propoſed and given drawings of wheeled-boats of a different conſtruction, larger wheels let into the bottom of the boat being uſed; and his boats are ſo contrived, that ſeveral of them, linked together by their ends, can be uſed together either upon a canal, or a rail-way, or plane. The ſame author has recommended and deſcribed a kind of flat-bottomed boat, with a ſingle or double rail-way on its floor, which he propoſes to receive or diſcharge a loading of rail-way waggons, as it lies in a ſhallow dock, from which the water has been drawn, and to which it is to be again admitted when the boat is to float out into the canal. For eaſe in getting loaded waggons in and out of theſe boats, a pair of leaves, or water-tight flaps, are contrived to let down, and permit the junction of the fixed rail-way on the land and the part thereof that is on the floor of the boat. A curious method of ſteering boats is in uſe on the Bedford, *Ouſe*, the *Cam*, and others of our eaſtern rivers: two boats are always uſed together, one of them having a ſtrong pole, or bowſprit, projecting horizontally from above its prow; this is brought over the ſtern of the boat which is to go before it, and the prow or ſtem of one boat is faſtened by a rope cloſe to the ſtern-poſt of the other: to the firſt boat the towing-line is fixed, and the bowſprit of the laſt boat is uſed as a tiller to ſet or retain the laſt boat to any required angle with the firſt, by which the laſt boat acts very effectually as a rudder for ſteering the firſt. Mr. *Chapman* propoſes to adopt this principle with ſmall boats upon canals. The weſt-country bargemen, on the Thames, guide or ſtop their boats, as they are floating down the ſtream by a long and ſtrong pole, with iron prongs at bottom and a croſs handle at top, round which they dexterouſly wrap a ſhort rope, faſtened to the ſide of the barge, when the pole has ſtruck into the bottom of the river.

For ſpeedily emptying the cargoes of ſmall boats into larger veſſels, Mr. *Davis Dukart* contrived, on the navigation to the Dungannon Collieries, to float his ſmall boats on to cradles or wheeled carriages, on which they were dragged up a ſhort inclined plane, and upon a rail-way conducted over the barges in the baſon; and then the boats could be turned over, and their contents ſhot at once into the barge. A different method, as Mr. *Chapman* informs us, is practiſed in South Wales: it conſiſts in continuing the canal (which may be a wooden trough) to the place of diſcharge, and terminating it on a caiſſon, ſuſpended on a tranſverſe centre; the boat being arrived at its place, the end of the canal is cloſed by a ſtop-gate, and the ſmall quantity of water contained in the caiſſon (which the boat ſhould as nearly as may be fill) being let out, the caiſſon with the boat in it may be turned over, as already deſcribed.

The *moving of Boats* upon canals or narrow rivers, where ſailing is impracticable, has always appeared attended with conſiderable difficulties. Where the width and depth of water will admit, long oars have been uſed, worked by one or two men on each ſide of the veſſel, as is done on the coal-barges and lighters on the *Thames* in or near London. On the *Tyne* river at Newcaſtle, their keels are ſaid to have been in uſe ever ſince 1378, and are rowed by an immenſe oar *on one ſide*, another being uſed at the ſtern to ſteer by, and counteract the tendency of this ſtrange mode of rowing. It is ſaid that the large oar is hung by an iron ring, ſo as to admit of its being laid on the gunwale of the keel, when not in uſe, but not of its being removed. Owing to the want of any regular and proper path on which horſes could travel by the ſides of rivers, the firſt hauling or towing of boats was performed by men, as ſtill continues to be the caſe on the canals of China; and in this country moſt of our navigable rivers were without horſe towing-paths till of late years. Within our recollection, ten or fifteen men were ſeen tugging at the hauling-line of a barge on the *Thames*, in the meadows of Twickenham. A good horſe-path now begins at Putney bridge, on the ſouth ſide, and continues uninterruptedly on one ſide or other of the river to the extreme points of the navigation. Theſe eſſential appendages to navigation are but now completing on the *Severn* river, which has been ſo long famous for its navigation. The towing-path on many of our old navigations is continually interrupted and broken off, by mills and other obſtacles, without any bridges for the croſſing of the towing-horſes and boys. On the *Ouſe* river, below Bedford, we have obſerved the towing-path to be interrupted at the end of almoſt every field, by high and dangerous ſtiles, over which the ill-fated navigation-horſes have to leap, encumbered by their harneſs and the heavy rope. No regular path is maintained, in a great part of the diſtance, by the owner of the navigation; but frequently the fine meadows there are cut up, by the track of the horſes being at a conſiderable diſtance from the river, acroſs the many bends that it has; and the farmer's graſs, between this path and the river, is rendered of little value, by the ſoiling and dragging of the hauling-rope over it; the banks of the river are alſo miſerably worn away, by hauling ſo far from, and conſequently ſo obliquely to, the direction of the ſtream. In many places, where the river is wide, there is no track for hauling, except along the bed of the river itſelf; where often the horſes, with a wretched boy upon one of them, are ſeen ſometimes wading, and at others ſwimming, along the courſe of the river! Nothing is more common than ſeeing the horſes and boy have to ſwim over from one ſide of the river to the other, when the hauling-way changes; not unfrequently this is impracticable, from the total want of a way on either ſide, and the poor horſes are obliged to leap from the bank, perhaps when at a conſiderable height and diſtance, into the head-room of the barge, to the great peril of their bones and neck: ſhortly after, theſe wretched animals, and probably with a boy on their backs, are forced to jump out again, and perhaps plunge into the deep river and ſwim on ſhore, to reſume their labour of towing. A correſpondent of Dr. *Anderſon* has expatiated (*Recreations*, v. 318.) on the barbarous ſight of ſix horſes harneſſed at length, towing a barge up the *Thames* above Putney, by a ſingle line of inſufficient length, by which the hind horſes were in continual danger, in ſpite of their utmoſt exertions, of being precipitated into the river: what would this humane gentleman have ſaid, if his walk had been along the banks of the *Ouſe*, on a piercing winter's day? It is owing, in a great meaſure, to the enormous difficulties and expence of conſtructing and maintaining a proper horſe-path by their ſide, that the navigation of many of our rivers is ſo imperfect. In all flat countries, except the river is embanked, as in Cambridgeſhire, Lincolnſhire, &c. and without any wide waſh or fore-ground within the banks, the towing-path often cannot be made up above the reach of the floods, but, during every floody ſeaſon, will be under water and uſeleſs; and perhaps, when the water ſubſides, it will be found carried away by the force of the current for great lengths together. On ſome of our canals, the practice at firſt prevailed of towing by men; and the ſame ſtill continues on the *Stroudwater* canal, whoſe towing-path has *ſtiles* upon it, like thoſe of a foot-path, at the diviſions of different perſons' lands. Horſes are now, in general, uſed for towing boats on our canals, except the late duke of *Bridgewater*'s, who reared a large and fine herd of mules, that were found to anſwer ſo well, that none others are uſed to this day, we believe, on that canal. Except with paſſage-boats, and flies or packet-boats, for the expeditious conveyance of packages and parcels, the uſual rate of tracking or towing upon our canals is about 2½ miles per hour, including the time loſt in paſſing the locks, which, if of 8 feet riſe, will require about 5½ minutes each.

It is certain that there is hardly any limit to the load, which one horſe can move, in a number of barges attached together, when going with a proportionally ſlow pace; and this has occaſioned ſome canal advocates to aſſert that one horſe will, on a canal, draw as much as 60 on the road; while Mr. *Robert Marſhall* has aſſerted, that horſes will not be able to move more than 15 miles per day with deep laden barges on a level canal. On moſt of the wide canals it is uſual to employ a horſe to each barge, or to a pair of boats of half the width each that the barges are. It appears, that on the *Ketley* canal, on *Bridgewater*'s canal between Worſley and Mancheſter, and others, ſeveral of the ſmall boats in uſe thereon are linked together, and drawn by one horſe or mule; there being projecting and ſmooth rails provided on the *Ketley*, at all the convex points of the bank, to keep the boats in their proper track. Mr. *Fulton* has imagined, that 15 or 20 of his ſmall rectangular boats, linked together, could be drawn by one horſe, and be kept in their proper line upon the canal by a man with a boot-hook walking by the ſide of them on the towing-path. Beſides the methods of rowing and tracking, which we have been mentioning, on the *Tyne*, the *Thames*, and moſt of our rivers, hitchers, ſets, puys or poles, are uſed for ſhoving of barges along: the gunwale of the keels or barges is made wide and convenient to walk upon, and the boatman, being at the head of the barge, ſets his hitcher againſt the bottom and ſhoves againſt it, walking along the gunwale of the barge until he has arrived at the ſtern; when he draws up his hitcher quickly, and returns to the head to repeat the ſame operation, and this ſometimes on one ſide of the barge and ſometimes on the other, unleſs there are two men ſo employed, whoſe equal action could keep the barge in its direct courſe. This laſt method might be more uſed than it is upon canals; but from the neceſſity which moſt of them have found, for prohibitory clauſes in their act, againſt the uſe of any pointed poles, particularly ſuch as are ſhod or tipped with iron, on account of the damage which ſuch often do, by penetrating and diſturbing the lining and banks of the canal, and cauſing it to leak. We have heard of an attempt lately, to introduce a kind of hitcher-iron on the *Grand Junction* Canal, which ſhould preſent a flat end or ſurface, ſufficient to prevent its penetrating the facing on the bottom or ſides of the canal, and having a ſmall turn up at the point, which might remedy the loud complaints of the boatmen, at being debarred a hooked pole on board their boat, by which a comrade, who has the misfortune to fall overboard or into a lock, might be dragged up to the ſurface of the water. We have thought that it might be worth while, particularly in crooked and difficult parts of a canal for hauling, and where rubble ſtone or gravel is in plenty, when a wide canal is cutting, to form the covering of the lining, or the facing of the bottom, and perhaps of the lower part of the ſides alſo, of gravel or rubble inſtead of earth, and carefully to level and ram or roll the ſame down like a road, ſo that hitchers might be uſed freely thereon as on the bottom of a river. There would ſtill, however, require very ſtrict and well enforced regulations, to prevent the walls of the bridges, locks, tunnels, &c. from being pecked and greatly damaged by the points of the hitchers. Slide-rails will alſo be neceſſary, in and near the locks or tunnels, as we have mentioned in ſpeaking of the Bliſworth tunnel, which can, without damage to the walls, be removed, when decayed or worn out. Before we proceed to the ſubject, that has perhaps produced the greateſt number of unpractiſed mechanical inventions that are any where elſe to be found, we mean for *moving boats* by an impulſe from within or accompanying them, we have one other thing to mention, viz. that Mr. *James Jordan*, in his patent of the 24th of May 1796, for bridges, before quoted, has propoſed the uſe of circulating chains acroſs an aqueduct bridge, for towing boats over the ſame; and avoiding the expence of the extra width for, or lateral ſupport of, a towing-path thereon.

The volumes of the *machines approved by the Academy at Paris*, and the *cabinet* of *M. de Servier*, printed in 1719, contain plates and deſcriptions of many different contrivances, deſigned for *propelling or rowing of boats* on canals and rivers; one kind of theſe, which we ſhall firſt notice, depends upon gaining an impulſe or hold agaiſt the ground at the bottom of the river or canal; in one of which, a ſmall boat moved by oars was propoſed to be employed in ſucceſſively carrying forwards and dropping anchors whoſe ropes were to be attached to a horſe-gin on board of a barge, which was deſigned to tow or drag a great number of others. In another, a ſpiked wheel was propoſed to roll on the bottom of the canal, attached by a frame moveable on hinges at the ſtern of a barge, where a roller turned by a winch, was to give motion to the ſpiked wheel and propel the barge, by means of an endleſs rope or chain. See alſo *Walker's Lectures*, 4to. page 350. A ſecond kind depended upon the ſame principles as an oar, except in the conſtruction and mode of applying the power. On the 20th of July 1796, Mr. *Thomas Potts* took out a patent, for the uſe of a large flap or oar, moving on an horizontal hinge, upon a framed lever at the ſtern of a barge, intended when the handle of this lever was lifted up by ſeveral men, to turn on its hinge and preſent but little reſiſtance; but on the deſcent of the lever, its whole ſurface was by the action of the men at the lever, to be exerted on the water for propelling the barge: ſee *Repertory*, vol. vi. p. 160. In the year 1801, Mr. *Edward Steers* took out a patent, of which we have ſeen only a ſhort extract in the *Monthly Magazine*, vol. ix. p. 486, from which we underſtand his invention to differ but little from the above, except in having two paddles or oars. Mr. *Robert Beatſon* took out a patent, for applying the principle of luffer-boards or venetian-blinds to ſeveral purpoſes, which he has explained at length in his *Eſſay* printed in 1798; and at page 60, propoſes to propel ſhips by large oars or fins of this kind to be hung on the ſides thereof by hinges, and worked by a lever, as a rudder is by its tiller; poles with ſquare frames fixed on their ends, to puſh againſt the water behind the veſſel are alſo deſcribed. A third kind, depending on the reverſe of the action of an underſhot water-wheel, has had many advocates; the firſt that we have met with in our own country, is Mr. *Thomas Savery* in 1698, whoſe contrivances are ſhewn in *Harris's Lexicon Technicum*, art. Engine; it conſiſted of 6 or 8 paddles like thoſe of a water-wheel on each ſide of the veſſel, fixed on an axis acroſs the ſame, on which was a trundle head, and under this a wheel working into the ſame, by the force of a capſtan to be turned by men. We are told, that in the year 1781, the *abbé Arnal* propoſed to apply the power of a ſteam-engine on board of a veſſel, for working paddles, ſomething like the above, we believe. Soon after this period, we remember ſeeing on the ſhore of the *Thames* at Weſtminſter, a ſmall barge with a water-wheel in a cavity in its ſtern with a ſteam-engine for working it, which was ſaid to be the contrivance of *earl Stanhope*, and had been tried with ſucceſs againſt the tide in the river. In the year 1797, a veſſel having rowers by its ſide, that made 18 ſtrokes per minute, from the action of a ſteam engine on board, was tried on the *Sankey* canal near Liverpool, by which it was propelled 10 miles and back again to the ſame place: ſee *Monthly Magazine*, vol. iv. p. 75. In the ſame year, Mr. *Walker* (the lecturer) made ſome experiments on the *Thames* at Reading, and cauſed a boat to row itſelf againſt the ſtream. See his *Lectures*, 4to. page 349. About the year 1800, *Meſſrs. Hunter* and *Dickinſon* took out a patent, for a propeller for ſhips, which was tried in January 1801, on board of a government ſloop off Deptford on the *Thames*, and the ſloop thereby made way againſt the tide at the rate of three knots an hour. *Monthly Magazine* vol. xi. p. 195. In the *Journals of the Royal Inſtitution*, about the year 1802, there is a deſcription of an improved application of the ſteam-engine, to the turning of a wheel for propelling boats; the cylinder of this engine is horizontal, and the wheel with paddles is in a cavity in the ſtern of the boat, which therefore has two rudders, one on each ſide of the wheel, connected together by croſs rods. A veſſel of this kind was conſtructed for the *Forth and Clyde* canal company, under the direction of Mr. *Symington* the inventor, and in a trial made in December 1801, it drew three veſſels of 60 or 70 tons burthen each, at the rate of $2\frac{1}{2}$ miles per hour on their canal: ſee *Agricultural Magazine*, vol. vii. p. 152. We read in the laſt mentioned work, vol. ix. p. 218, that Mr. *Robert Fulton* exhibited a veſſel on the *Seine* at Paris, in Auguſt 1803, having two wheels with paddles, worked by a ſteam-engine, and that two other veſſels were towed by it againſt the ſtream at the rate of 3 miles per hour. A fourth kind of boat propellers, has depended on the rotary motion of a ſcrew, or fliers like thoſe of a ſmoak-jack; Mr. *Daniel Buſhnel*, in his attempts to navigate ſub-marine veſſels, as related in the *Tranſactions of the American Philoſophical Society*, vol. iv. p. 303, uſed oars, placed near the ſides and top of the veſſel, formed upon the principle of a ſcrew, the axles of which entered the veſſel, and by turning the ſame one way, the veſſel was made to advance or deſcend, as it was to recede or aſcend by a contrary motion of the ſcrew. Mr. *John Vidler* has contrived a veſſel, which has been lying, and occaſionally tried in the *Thames* at Weſtminſter, for 2 or 3 years paſt, that has a boom hung by an univerſal joint (Hook's) at the ſtern thereof, to a rotative axis, turned by a capſtan upon the deck of the veſſel; at the end of this boom is fixed a circle of ſtrong flyers, juſt like thoſe of a ſmoak-jack, which by ſtriking the water obliquely as the boom is turned round, propel the veſſel forwards; near to the flyers there is a collar on the boom that turns eaſily therein; to this collar ropes are attached, which go to different parts of the ſtern of the veſſel, and by which the boom, when in motion, can be drawn up quite out of the water, if its propelling action is wanted to ceaſe on any temporary occaſion, or the flies thereof can be let down into the water to any depth which may be required, or be turned aſide from the direct line of the veſſel to ſteer her on any courſe, without waſting ſo much of the propelling power upon the rudder as is uſually done in ſteering; a rudder is however applied to the veſſel ready for uſe when occaſion may require. The fifth and laſt method, which we recollect to have ſeen or read of, conſiſts in pumping water, by a force-pump through an orifice or pipe at the ſtern, or end of the keel of the veſſel, with ſuch force as to propel the veſſel along, by the ſtroke of the moving column of water againſt the water, in which the veſſel floats; we are ſorry that our memory does not ſerve us to mention the name of the inventor of this method, or the work wherein we ſaw a deſcription of the apparatus. In the *Britiſh Magazine*, vol. i. p. 397, it is mentioned, that in the year 1800, a veſſel was conſtructed at Liverpool with a ſteam-engine in it, which was moved along without the intervention of any machinery; we think this as likely to have been, an application of the pumping principle above mentioned. Although, as we hinted above, none of the mechanic contrivances here mentioned have been adopted in practice, we truſt our readers will not be diſpleaſed, at the ſhort notice which we have given of each, with a view to preſerve their memory, and in hopes that the thing may yet be accompliſhed.

On the *repairing of Canals* we think it neceſſary to ſay ſomething; and to begin, by recommending the adoption of a ſyſtem of management, by which the eaſieſt notice of any defect, or want of reparation, will be obtained: that in ſtore-houſes, at proper places on the line, a ſtock of oak, elm, and deal timber ſhould conſtantly be kept, cut out and ſeaſoned, ready for replacing any of the timbers or planks in the locks or other works, with the leaſt poſſible delay to the trade; a circumſtance which, if not attended to, may prove of incalculable injury to the credit and ſucceſs of the concern. Sound and good bricks, and ſtones, ready for replacing any which are liable, or obſerved to be likely to want repair, ſhould alſo be in readineſs, and good cement ſhould always be kept in readineſs, on ſome part of the line from whence the quantity wanted may be ſpeedily tranſported to any part where a reparation of the walls, bridges, culverts, &c. may require the ſame: however, before emptying any part of the canal, or interrupting the trade for any reparation, a ſtrict ſearch ſhould be made throughout every part in that level, or on the adjoining ones, to diſcover all the defects therein, that arrangements may be made beforehand for repairing the whole at once, or with as little delay as poſſible, while the trade is interrupted on the line. In every ſtore-houſe a conſiderable number of the *pile-planks* before deſcribed ſhould be kept piled up in readineſs, for making temporary ſtanks or dams, in order to empty any particular part of a level, which may have a culvert, trunk, ſluice, ſtop-gate, lock-ſil, or other thing which is damaged, out of order, or decayed. It is ſurpriſing, to thoſe who have not ſeen ſuch works performed before, with what facility the workmen who are uſed to this buſineſs will drive two rows of pile-planks ſo regular and cloſe to each other, that by the help of the tongues or ſlips in their grooves, and often without, a tight ſtank is made without any earth or other looſe matters to ſtop the water; and between two of theſe ſtanks, if ſuch are neceſſary, they will empty the water, by chain-pumps, or water-ſcrews, to get at any culvert, or other matter, to be repaired or altered; there have been inſtances of theſe operations being performed, and of the part being filled with water, and the plank-piles drawn up again for the trade to paſs, in the ſpace of eight or nine hours. Should any part of the canal appear to want new lining or puddling, owing to a neglect at the time of making of the canal, or to any ſubſequent accident, care ſhould be taken to chooſe the time for ſuch works, when the trade can beſt bear an interruption; and as, on the average of ſeaſons, the trade is two or three weeks interrupted by ice, during the months of January and February, it may not be amiſs to embrace that period, on ſome occaſions, although the work may be longer about, and ſome additional expence may be incurred by covering up the work with earth, before it is left at night, to prevent its freezing, and in removing all ſuch puddle, &c. again in the morning, or at beginning work, which ſhall be found frozen. Previous and explicit notices ſhould be given of all intended interruptions to the trade, as long beforehand as is neceſſary, to enable the traders to ſupply ſtocks of articles at the places of conſumption on the line, and to avoid having their barges locked in, and perhaps lying idle, when they might have been employed if they had been on a different part of the canal.

It is an eſſential point of good management to have experienced mole and rat-catchers employed from time to time upon the line of a canal, to extirpate theſe hurtful vermin; and in every inſtance of diſcovering one, to trace out all his burrows and holes, and have them carefully ſtopped up and filled in every part, as well for preventing the harbouring of other animals of the ſame ſort, as for preventing the water from making its way into and through them. On a canal in Surry, we are told by Mr. *Robert Marſhall*, in his *examination of a canal and rail-way*, &c. that a *mole* or *rat-hole* only, occaſioned, after the hard froſt of 1795, the rupture of the canal in a high embankment, by which more than 100 yards in length of a lofty bank was precipitated into the meadows and river below, and that a barge which before lay enveloped in the ice on the canal, was hurried down through this gulph into the river! It is impoſſible to take too much care againſt ſuch fatal diſaſters as theſe, and the duty of the mole and rat-catchers ought not to be limited to the company's ground, but in all fields, banks, ponds, or brooks within 100 yards or more of the canal, on each ſide, they ought to be equally attentive to the deſtruction of ſuch vermin, and the demoliſhing of their ſecret retreats. The ſame men might very properly be employed in pulling up and extirpating all large and ſpreading weeds from every part of the banks of the canal, and in mowing down the herbage occaſionally; theſe circumſtances being not leſs eſſential for the neatneſs and beauty of the canal, than to prevent the firſt harbour of vermin of different kinds. The banks of the canal will be very apt to continual wear at the ſurface of the water, and for ſome height above and below that level, if a proper kind of herbage is not encouraged upon the ſlope of the bank: conſiderable care ſhould be taken to ſuffer no plants to take root on or near a canal bank, or ſpread its ſeed, (if poſſible to prevent it where water is taken into the canal by a feeder), which will grow in deep water, or whoſe roots are large, hollow, and ſtrike deep into the ground, leſt the former of theſe ſhould choke the canal in time by weed-beds, and the latter render it leaky by the formation of numerous open tubes through the lining into porous ſtuff. None but thoſe who have ſeen many drains or new ditches opened in wet and boggy ground, can be aware of the depth, ſize, and number of hollow roots, which ſome of the aquatic plants, as the *equiſetum paluſtre*, or marſh horſe-tail, the *iris pſeudacorus*, or yellow flag, and ſeveral others, ſend forth into the ground.

Puddle-ditches, in the banks that are raiſed or made up, are a great ſecurity againſt the bank being waſhed down, in caſe of the water, riſen by any ſudden thunder-ſhower, or other inordinate rain, breaking over the top of it; as ſoon as the puddle is reached, the effect of the ſtream to tear and lower the bank will often be ſtopped; for good puddle, when properly ſet and hardened in the centre of a bank, is ſo compact as not to be liable to be abraded or ſuddenly worn by a current of water. In caſe of the breaking or ſlipping of a bank, ſo that a conſiderable and wide breach is formed, and ſtill increaſing, it is a good practice to drive in two rows of common fold hurdles, at a foot or leſs apart, laſhing the ſame well together by cords, and ſecuring them by ſtrong ſtakes drove down behind them, and if the ſtream of water be deep through the breach, it will be neceſſary to drive other long ſtakes obliquely into the ground, and ſecuring their tops to the hurdles and upright ſtakes by laps of cord, that theſe laſt may act as ſtruts to prevent the whole being borne away; into the cavity between the hurdles; ſtraw or ſtubble ſhould then be put and trod down, beginning at each end and working towards the middle, in order to prevent the current being turned, with freſh impetuoſity, againſt the ſides of the breach; ſuch a dam as this will prevent the loſs of any conſiderable further quantity of water, and will render the water ſtagnant, ſo that a row or more of pile-planks can be drove to cut off the connection with the breach, which can then be emptied of water, the hurdles and ſtraw removed, and the reparation begun, with proper puddle-ditches for its ſecurity, as before deſcribed. At the famous Dagenham breach of the embankment of the *Thames*, dove-tail, or plank-piles were uſed, we are told. It will be neceſſary to defend many places of the banks of a canal that are obliged to be unuſually ſteep, as in the approach to a bridge or lock, a wharf, &c. with a facing of planks, called *camp-ſheeting*; this conſiſts of ſtrong piles driven into the bottom of the canal, with the proper inclination, with horizontal pieces, or land-ties to their tops, on to which piles ſound and durable planks are ſpiked. In ſome places, owing to the accidental or unavoidable admiſſion of very thick water into a canal, or in more caſes by the ordinary depoſit in length of time, the canal will become choked with mud. In theſe caſes a machine with buckets, like a chain pump, to ſcrape the bottom of the canal, and afterwards diſcharge the load of mud into a barge, might be uſed, ſuch a machine, worked by horſes, being now in uſe in the *Weſt India Docks*. See alſo *Walker's Lectures*, 4to. p. 35. The late Mr. *Brindley*, we are told, contrived a plan for the purpoſe of clearing the docks at Liverpool from mud.

By neglect it will ſometimes happen in canals, that *Weeds* grow up from the bottom, and form an unſufferable impediment to the motion of the barges; and this is almoſt unavoidably and generally the caſe in river navigations, if conſtant care is not uſed to tear them up, or cut them down. On the great *Ouſe*, and other fen rivers, a machine has been long in uſe, called a *bear*, for tearing up ſtrong weeds by the roots.

About the year 1796, the *chevalier Bentancourt Molina* preſented to the *Society of Arts*, a model of a barge, having a windlaſs in its ſtern, which gives a circular motion to a pair of knives or ſcythes, or a lever giving an alternating motion to knives for mowing off weeds cloſe to the bottom of a canal, in which the barge is to float, or on the ſloping ſides of the canal; for which purpoſe, the knives can be made to revolve at any depth below the ſurface of the water, and either horizontally, or inclined in any angle; this model may be ſeen at the ſociety's houſe in the Adelphi, and a deſcription and view of it will be found in their *Tranſactions*, vol. xiv. p. 345. or *Repertory*, VI. 169. In moſt winters it happens, that an ice not more than an inch or an inch and half thick, continues for a conſiderable length of time on canals, and other ſtagnant waters; this, or even a leſs thickneſs of ice is ſufficient to ſtop the trade upon canals, unleſs the ice is broken; and, for this purpoſe, it is adviſable, every morning of a froſt, unleſs the ice ſhould be found more than uſually thick, and the froſt increaſing, and likely to continue, to break the ice on each pound; this is uſually and effectually done by a ſtrong and ſquare headed barge, whoſe ſloping or projecting head is covered with ſtrong iron plates. One of theſe barges being drawn along the canal, and into each lock, by ſeveral horſes, has a conſtant tendency to riſe up upon the ice, and thereby breaks it down before the barge: about the lock-gates it will be neceſſary to break the ice by ſtamping with the end of a pole. Mr. *Symington*, whoſe barge, with a ſteam engine in it, to propel it along, and tow other veſſels, we have lately mentioned, has provided the head of his barge with ſtampers, to be worked by the engine, for breaking of the ice before it, in froſty weather.

Leaks in a canal may ſometimes be ſtopped without emptying the water, if the depth will permit it, by preparing good puddle in a flat-bottomed dirt-boat or flat, and dropping the ſame in ſpadefulls equally over the ſurface, and when a certain length is done, raking the ſame about with a rake, with ſhort teeth to join the pieces together, and level the bottom. The difference in ſpecific gravity, in different loams and earths, is ſo conſiderable as to make ſome of them much more proper for the lining and facing of a canal than others; the heavieſt that can be found ſhould be uſed when leaks are to be ſtopped, and the water remain in the canal as above. We have paſſed along the branch of a canal on a chalk ſoil, where the lining of the bottom was ſo light, that the motion of the barge ſtirred enough of it up into the water, which was before nearly clear, to make it almoſt as white as milk behind us; this light ſtuff has ſince been taken out, and a ſubſtantial lining and facing of proper ſtuff, brought in barges for the purpoſe, and laid on the bank before the water was let out, has been applied, by an able engineer, who ſucceeded thoſe of too different a deſcription who conſtructed this very leaky branch.

Some *Implements* and machines are uſed in the making or working of inland navigations, which we have not had occaſion yet to mention or deſcribe. In every conſiderable work it will be neceſſary to erect rolling-ſtones for grinding and preparing of the cement or mortar that is to be uſed in the water-works. At Worſley, on *Bridgewater*'s canal, the power of a water-mill is applied to turning ſeveral pair of large ſtones on edge, like thoſe uſed by tanners, gunpowder-makers, &c.; in ſome of theſe the ſtones rolled round on a fixed ſtone, in others a large caſt-iron flat pan, in which the materials to be ground were put, was turned round under the ſtones, which were thus made to revolve round their own fixed axis on the materials. What appeared ſingular in the proceſs at this place was, that the lime and other ingredients were ground with water for a long time, in the ſtate of thin mortar, which was then removed into ciſterns to dry, and before the ſame was become too hard, it was cut out by a ſpade, into lumps of about half a cubic foot each, and heaps of them were preſerved in a ſtore-room, where they became quite dry, and as hard as chalk, or harder, for uſe at diſtant periods of time, in the repairs of the walls and works under water. At the *London* and *Eaſt India* docks ſteam-engines, of twenty horſe power in one caſe, were uſed for grinding their cement; but the pozzolana, lime, and other ingredients are here mixed and ground together in due proportion in a dry ſtate (as *Parker* and Co.'s patent Roman cement is done), and it is not wetted, but carefully preſerved from moiſture, till a very ſhort time before it is to be uſed in the walls, &c. See the article Rolling-stone.

The *driving of Piles* is a very conſiderable buſineſs in many large concerns; at the entrance of the *London Docks* a ſteam-engine was erected for driving the vaſt number of piles which were required for the coffer-dam. Mr. *S. Bunce* contrived a very ſimple and effective kind of pile-driver, to be worked by men at a winch. Mr. *Harvey* contrived a double pile-driver, which is deſcribed in the *Tranſactions of the Society of Arts*, vol. xii. p. 337. The horſe pile-driver contrived by M. *Vauloue* cannot, from the almoſt innumerable models, plates, and deſcriptions which have appeared of it, ſince the building of Weſtminſter Bridge, be unknown to any of our readers. Mr. *John Fould* contrived a machine, and preſented a model of it to the *Society of Arts*, (ſee their *Tranſactions*, vol. xiii. p. 280) for cutting off the tops of piles, after they have been drove, beneath the ſurface of the water. See the article Pile.

Some of the navigator's tools and implements, as barrows, horſing-blocks, grafting-tools, ſhovels, and ſcoops, we have repreſented in *figs.* 48 to 52, *Canals, Plate* VII.

*Cranes* for the hoiſting of goods will be required on the wharfs of canals and rivers. See our article Crane.

On the *general management*, and office department, of a canal concern, it is unneceſſary to enlarge. The committee with which the conduct of it is entruſted will, without doubt, direct their attention to thoſe various circumſtances on which its proſperity depends. Accordingly, they will appoint proper officers in the ſeveral ſubordinate departments, and give them ſuch inſtructions for the regular diſcharge of their duty as occaſion may require. It may not, however, be improper to ſuggeſt, that the canal committees ſhould direct their reſident engineer to eſtabliſh proper rain and evaporation gauges at ſeveral lock-houſes upon the line, to be kept by the lock-keepers, and regiſtered daily or weekly with great care: theſe obſervations, preſerved in the company's books, or, what would be better, publiſhed in ſome of the magazines, would prove of great advantage to ſcience, and to canal undertakings in general. In canals of conſiderable length, particularly if ſome parts of them are indifferently and variably ſupplied with water, or leaky, it will be right to fix gauges or graduated rods on each upper lock-gate, that would ſhew at all times how many inches depth of water there is at the time, in the ſhalloweſt part of that pound; and to cauſe the lock keepers to mention the ſame at the foot of the printed permits or paſs tickets, that the toll-clerks ſhould give to every bargeman who paſſes, containing the number and deſcription of each barge, and the deſcription and weight of its loading; theſe, tranſmitted regularly to the toll-collector, would enable him, or ſome other perſon, to keep for the information of the committee, a regiſter of the daily ſtate of each long or leaky pond of water; at the ſame time that the lock keepers, toll-clerks, &c. at each extremity, and on different points of the canal, would always be acquainted with the ſtate of the water, and the loading which a barge could paſs with at every particular place; and could inform bargemen; for want of which knowledge great delay and expence are often incurred, in dry ſeaſons, by ſetting off with more lading than can be carried through, for want of a ſufficient depth of water, and part of the ſame is obliged to be left on the road, or taken into other boats. All the regulations contained in the act, for working of the canal, and ſuch by-laws as the committee may ſee it neceſſary to make, for regulating the conduct of the bargemen and others on the canal, ſhould be printed, and ſtuck up at every wharf on the canal, and in every toll-clerk and lock-keeper's houſe; and all the company's agents and ſervants ſhould be ſtrictly enjoined to notice every breach of theſe rules and regulations, not by altercation with the offenders, but by immediately noting down in writing the exact and true particulars, of the time, place, and name of the offender and bye-ſtanders or witneſſes, &c. tranſmitting the ſame immediately to the committee, and preſerving a copy thereof themſelves: and, though we are far from recommending [illegible] in puniſhing on theſe occaſions, yet a ſyſtem of this ſort, by ſhewing the offenders that the committee would always be prepared to proceed againſt them, would, in moſt inſtances, eſpecially if the parties were written to, to threaten them, go a great way to prevent the ſame parties or others from offending again.

*Tonnage Tables*, fully and explicitly ſtating the toll or tonnage payable to the company, on goods or articles of every different kind, or on different parts of the line, if, as often happens, theſe vary, ſhould be printed and ſtuck up on all the wharfs and toll-houſes, for preventing all doubts or altercations between the company's ſervants and the traders. At ſome convenient place on the line of the canal, a *weighing-houſe* ſhould be prepared, conſiſting of a dock under cover, large and deep enough to contain the largeſt veſſels which are to navigate the canal; this dock ſhould be furniſhed with a draw-gate to let down, or doors to ſhut, when an empty barge has entered, in order to render the water quite ſtill within the dock. Caſt-iron or leaden weights of 2 cwt. each ſhould be provided, and a crane to hoiſt the weights readily in or out of the barge, and place them in any part of the ſame, ſo as always to load her evenly. To this weighing-houſe, the act or by-laws ſhould require every barge to be ſent, having the name thereof, and the owner's name and reſidence previouſly painted on the ſtern of it, before it is allowed to trade on the canal: the empty barge being arrived in the dock, the gauging-maſter fixes four ſmall plates of iron, each containing the *number* that this barge is in future to be diſtinguiſhed by, two on one ſide, and two on the other, againſt the gunwale, near the head and ſtern. Theſe plates are all fixed at the ſame diſtance from the ſurface of the water, when the barge is empty; this diſtance, in inches and tenths, is entered into the gauging-maſter's book, under the number of the barge, name, owner's name and reſidence, date, and other particulars; two tons of weights are then hoiſted into the barge, and regulated until the diſtance from all the four plates to the water's ſurface is the ſame, which diſtance in inches and tenths is alſo entered in the book againſt two tons; two tons more of weights are then hoiſted in and adjuſted, and the height of the number-plates above the water is taken and entered againſt four tons as before; theſe operations being repeated until the utmoſt lading of the barge is on board, when the weights are taken out again, and the barge removed from the dock. For meaſuring the height of the plates at the Paddington weighing-houſe, a tin tube is uſed, that is furniſhed with a float moving freely in it, to mark the ſurface of the water, which carries a light ſtick graduated to inches and tenths, to ſhow the height of the number-plate againſt which it is applied. At every toll-houſe on the *Grand-junction* canal ſimilar floating-rods are kept, and to every laden barge which paſſes this gauge is applied againſt the number-plate, at each end, and to thoſe on the other ſide, if the barge appears to heel at all to either ſide. If the dry inches and tenths ſhewn by the gauge, between the number-plate and the water's ſurface, are different, they are added together, and divided by the number of them for the mean height. It is the buſineſs of the gauging-maſter to calculate, from the particulars entered in his book, of each barge as above, the weight to the neareſt of $\frac{1}{4}$ of a ton, which anſwers to every inch and tenth of an inch, of the dry inches ſhewn as above by the gauge; the number of the barges are applied in a regular ſeries, in the order in which they come to be gauged; and a book, containing a table for the tonnage on board, anſwering to every dry inch and tenth, as above, is calculated, and a copy of each is in the poſſeſſion of each toll-clerk, by a reference to which, he ſees and enters in his toll-book, and in the paſs-ticket or permit, the number of tons and quarters for which tonnage is to be paid to the company. On a great number of canals the practice is different; the gauging-maſter prepares four ſlips of copper or lead, about $\frac{3}{4}$ of an inch broad, and $\frac{1}{8}$ thick, and ſtamps thereon at every diviſion anſwering to two tons, agreeable to the obſervations entered in his book, and between theſe ſtrokes are drawn to mark the intermediate tons and quarters of a ton. Theſe plates he ſees carefully nailed on to the ſides of the barge, under the number-plate; by help of which the toll-clerk, and the bargeman alſo, can at any time ſee the tonnage on board, by the place on the plates cut by the water's ſurface.

Moſt acts contain a proviſion reſpecting barges occaſionally navigating a canal, or any others where reaſon appears to the toll-clerk to ſuſpect a deception or fraud, for requiring the bargeman to give an accurate account of his lading on board; which if unſatisfactory, the toll-clerk may take ſuch barge to the neareſt wharf where accurate ſcales, ſteel-yards, or engines for weighing goods are kept, and there have the cargo unloaded and weighed; which expence, as well as a penalty, the bargeman is made to pay, if he had refuſed or neglected to give an account of his lading, or if his account ſo given ſhall prove below the real weight of the goods. New barges are uſually indulged, in two or three voyages, before they are gauged, in order the better to ſuit the bargeman's and gauging-maſter's convenience for doing it, during which they are ſubject to have their goods weighed, as they alſo are, whenever they have different goods on board, liable to different rates of tonnage, and do not give a ſatisfactory account of the weight of each.

In many acts there are clauſes inſerted to prohibit the planting of trees in the canal-hedges, or on its banks, as there are alſo in others, for reſtraining the company from erecting any houſes or buildings on the banks of the canal, except certain ſpecified public wharfs, unleſs for the immediate uſe of the canal. A clauſe will be neceſſary, to puniſh perſons who are found throwing ballaſt or any kind of ſoil overboard or into the canal, by which it might be choaked up: it will alſo be requiſite, ſtrictly to prohibit the throwing of looſe ſtuff, as chalk, gravel, ſand, &c. by means of ſhovels, from heaps or barrows on the bank, into any barge, unleſs a broad and cloſe ſtage of boards was firſt laid to catch the ſtuff, which will unavoidably ſcatter, and to prevent its falling into the canal.

Neceſſary tackle ſhould be kept in readineſs, for weighing up ſuch barges that are ſunk, without delay, on account of the total interruption that ſuch will often occaſion to the navigation. Where a ſunk barge lies ſo that another barge cannot be floated on each ſide of it, the following method may be adopted: chains ſhould be looped round the ſunk barge and hooked, having four ends of ſufficient length proceeding from near the four corners of the barge, two empty barges ſhould be brought, one to each ſide of the ſunk one, and ſtrong beams of timber be laid acroſs each of theſe barges, and the ſpace between them; water ſhould then be admitted into each of the barges by their plugs, to ſink them almoſt to the water's ſurface, the plugs ſhould then be put in, and the four chains be faſtened tight to the croſs beams, when a pump ſhould be uſed in each of the barges to throw out the water, and as this is accompliſhed, if the chains are properly fixed, the barge will be buoyed up, often to the ſurface of the water, ſo that ſhe may be freed by pumping her; if not, ſhe muſt be ſhoved along, ſuſpended between the light barges, to ſome ſtrong crane, where ſhe can be further aſſiſted, or into ſome dock or ſhallower place, where ſhe can be relieved by a repetition of the ſame proceſs.

Several further *Regulations for working of Canals* require yet to be mentioned. They are ſuch as relate to the penalties that ſhould be provided in the act or by-laws for preventing bargemen from taking in above a certain weight, adapted to the ſize of their boat and the depth of the canal; and alſo for preventing ſuch boats from damaging the lock-ſils or bottom of the canal, or ſticking faſt to the interruption of other boats. The nature of the lading and the manner of diſpoſing it in the boat, ſo that the ſides of the bridges, &c. may not be injured, ſhould be duly attended to. Penalties ſhould be provided to puniſh thoſe bargemen who ſuffer their boats to ſtrike againſt any of the locks or bridges, or thoſe who ſuffer their barge to lie either for unloading or any other purpoſe, ſo as to obſtruct the paſſage of other boats. In ſome acts this penalty is fixed, by the hours that ſuch interruption continues, and at an increaſing rate. Boats left at wharfs or other places, on or by the line of the canal, ſhould be moored at both their ends. Bargemen ſhould be prohibited from fiſhing, or having tackle for ſuch purpoſe on board. It ſhould be provided, and made known by the by-laws, that barges or veſſels going one particular way on the line, and on each of the branches, ſhould give way for thoſe they meet or have occaſion to paſs; and on narrow canals or branches, it ſhould be provided, that when two barges that are meeting each other firſt come in ſight, or one of them hails the other, that which is neareſt to a paſſing place, ſhall ſtop at or go back to the ſame to let the other paſs. Common trading barges and veſſels, and all others, ſhould be prohibited from paſſing any locks or moving along the canal except in the day-time, and for this purpoſe it is uſual to divide the months of the year into three or four portions, and to ſpecify the hour both morning and evening in each, between which the canal is to be open. Light boats, for the conveyance of market-goods, parcels, &c. are allowed on ſome canals, as the *Grand Junction*, to paſs on during the night, their owner paying a ſpecified ſum for a licence for ſuch privilege, engaging to employ the moſt careful and experienced boat-men, and to make good all damage which ſuch boats may do to the works of the canal, or to the barges or property of other traders. Mr. *Thomas Pickford*, the great waggon proprietor, has ſubſtituted boats in place of many of his waggons, and which travel night and day, and arrive in London with as much punctuality from the midland and ſome of the moſt diſtant parts of the kingdom, as the waggons do.

As few of the tunnels are conſtructed wide enough for two wide barges to paſs each other therein, it may become neceſſary in ſuch caſes, where the tunnels are long, to eſtabliſh an overſeer at each end of the tunnel, where a baſon of ſufficient dimenſions for ſeveral boats to lie and paſs ſhould be provided, to ſuffer no barges to enter at either end for an hour, or other period, or until the laſt boat from the other end is come out, to prevent wide ones meeting others in the tunnel. If the number of wide boats be very ſmall in proportion to the narrow ones, the periods for the entry of narrow boats may be ofteneſt repeated, and wide boats might, in extreme caſes, be only ſuffered to paſs the tunnel between the two baſons after dark in the evening, when the other boats are lying ſtill on the canal.

Gentlemen's pleaſure-boats, and narrow ſhort huſbandry-boats, for the uſe of the occupiers of the lands on each pound, are often allowed at very eaſy rates, if not quite free of tolls; and ſometimes ſuch, as well as any other boats laden with manures and road-materials, are allowed to paſs the locks on the ſame conditions, at ſuch times only as the water runs over the lock-weirs, or is within a very ſmall quantity, as half an inch, of that height.

The regulations of veſſels *paſſing the Locks* are uſually very explicit in canal-acts, that boatmen may not ſuffer the water to remain in the locks longer than is neceſſary for their boats to paſs; that every boatman in going down a canal, ſhall, previous to his bringing his boat into any lock, ſhut the lower gates of ſuch lock and the cloughs thereto belonging, before he ſhall draw the cloughs of the upper gates; and, after he ſhall have brought ſuch boat through the lock, he ſhall then ſhut the upper gates before he ſhall draw the cloughs of the lower gates, and in going up the canal, ſuch boatman, as ſoon as he ſhall have paſſed his boat through the lock, ſhall ſhut the upper gates of the ſame, before he ſhall draw the cloughs of the lower gates, unleſs there ſhall then be a boat coming down the canal, in ſight of the ſaid boatman, in which caſe the lower gates of the lock ſhall be left ſhut, and the upper gates ſhall be left open; and in all dry ſeaſons, or where there ſhall be a ſcarcity of water in the canal, the boat ſo going up (if within ſight of a boat ſo coming down,) and at a diſtance not exceeding two hundred yards below a lock, ſhall paſs through ſuch lock before the boat coming down, and then ſuch other boat ſhall come down into the lock; and if there ſhall be more boats than one, below and above any lock at the ſame time, in any ſuch dry ſeaſon, within the diſtance aforeſaid (which diſtance ſhall be diſtinguiſhed by a poſt ſet up for that purpoſe), ſuch boats ſhall go up and come down at ſuch lock *by turns*, until all the boats have paſſed, by which means one lock full of water may ſerve two boats. A penalty ſhould be provided againſt any bargeman or other perſon, who draws the cloughs, except while barges are paſſing as above, or for leaving any clough open; as alſo againſt any lock-keeper or other ſervant of the company who gives undue preference to any boatman in paſſing the locks, or in unloading his barge at the public wharfs. Poſts ſhould alſo be provided by the ſide of the locks, for ſtrapping or ſtopping the velocity of boats before they enter the locks, and penalties ought to be provided againſt the winding of their rope or ſtrap round any part of the gates or lock, in order to ſtop a barge, except the ſtrapping-poſts before mentioned; after all, the engineer ſhould be careful to form the heads of the gates, and all other projecting points about his locks, of ſuch a ſloping or wedge-like form, that the rope would have no hold upon them, but ſlip off. A clauſe ſhould always be inſerted in the act, for making maſter boatmen anſwerable for all damage done by their ſervants, giving them, however, the right of recovering from their ſervants in all caſes of wilful damage or neglect. On ſome canals it is uſual, for the maſters to hire their men by the ton of goods which they navigate certain diſtances, inſtead of paying them by the day for their time.

For ſome time paſt, the rate of *Freight* on ſome canals, over and above the company's tonnage, has been two-pence per ton per mile, for unperiſhable goods, threepence per ton per mile for periſhable goods, and fourpence halfpenny for bulk goods. In times of diſtreſſing ſcarcity, like thoſe of 1795 and 1800, the committees of ſeveral canals, have permitted the paſſage of imported grain, going towards the interior of the country, toll free, with the laudable intention of lowering its price to the community.

The *Principles of conſtructing River Navigations* require ſome further notice in this place, in addition to the particulars which we have already had occaſion to notice reſpecting them in this article.

Mr. *Thomas Telford* has given an account of the navigation of the river *Severn*, which is printed in *J. Plymley's Agricultural Report of Shropſhire*, pages 284 and 317, from which we ſhall collect ſome particulars, and remark thereon, with the view of ſhewing by an example, what are the nature and extent of the difficulties which navigation has to contend with, upon natural rivers. This juſtly famous river is navigable up to Welchpool, a diſtance of 155 miles by water, from the mouth of the Bath *Avon* river; the extreme branch of this river may be traced for about 45 miles above Welchpool, to Plinlimmon Hill, and numerous other branches extend for great diſtances into the country on both ſides; the whole of this great length of river navigation was till lately unimproved by art, it having no locks, weirs, or other erections throughout its whole length for ſurmounting the numerous ſhallows and irregularities, which the current over variable *ſtrata* had formed in its bed. The firſt, or loweſt 42 miles of this river, extending to the city of Glouceſter, are very wide for great part of the way, and have a moſt rapid tide; but the laſt 28 miles are ſo crooked, that ſhips are ſaid to be often ſeveral days in paſſing it; on which account, a grand canal, calculated for veſſels of 300 tons burthen, was in the year 1793 projected and begun, between *Glouceſter and Berkley*, of 18½ miles in length, for avoiding theſe 28 miles of the river. From Glouceſter to Worceſter the diſtance is 30 miles by the courſe of the ſtream, the riſe in this length being 10 feet, or at the rate of 4 inches in a mile: from Worceſter to Stourport the diſtance by water is 13 miles and the riſe 23 feet, or at the rate of 1 foot 9 inches per mile: from Stourport to Bridgenorth it is 18 miles, and the riſe 41¾ feet, or 2 feet 4 inches per mile on the average; and, from Bridgenorth to the New Town at the junction of the *Shropſhire* canal, called *Coal-port*, the diſtance is about 7 miles, and the riſe about 19 feet, being a rate of about 2 feet 8 inches per mile. It was, we believe, that excellent and public-ſpirited individual, Mr. *William Reynolds*, the founder of *Coal-port*, who cauſed an account to be daily regiſtered, of the depth of the ſtream in the bed of the *Severn* river at that place, between the 7th of October 1789, and the 23d of December 1800, of which Mr. *Telford* has given us the particulars, except on 12 occaſions when the river had overflown its bounds and covered the uſual marks, on Sundays during ſome part of the time, the intervals of froſt in which the river was frozen over, and for three ſhort intervals, when unfortunately the experiment was by ſome accident ſuſpended. Theſe valuable materials we have examined with conſiderable care, and ſhall preſent our readers with ſome reſults therefrom, that will be of uſe in judging of the interruptions from floods, drought, and froſt, to which river navigations are liable; and we do not apprehend that this river is more ſubject to them than the Britiſh rivers are in general, excepting thoſe ſmaller ones like the Colne, the Wandle, and others, which are ſupplied principally by ſpring-waters. During all the months of *January*, in the above period of 11 years, ending the 6th of October, 1800, the river was twice overflown, (2d Jan. 1790. and 27th Jan. 1800,) and exceeded, we ſhould ſuppoſe, the depth of 16 feet, that being the greateſt depth at any time recorded; and ſeveral times, when no depths are inſerted to the great floods, it is ſtated in the table that the water was above all the marks: beſides theſe, there were 32 ſmaller floods, or times when the water had riſen, and was falling again for ſome days after; the higheſt of theſe had a gations, or in extending the navigation thereon above the tide-way, it is of importance to examine the ſtate of the whole country, to which the river in queſtion acts as a drain, to obſerve accurately whether cultivation, or the breaking up of lands, and the practice of draining have been going on, or are likely to be ſo in any conſiderable degree, within a reaſonable period; as alſo to obſerve particularly the ſtate and extent of the valleys and meadows, over which the waters are or have been ſpread in ordinary floods, and the probability of ſuch being further prevented by ſtraightening or enlarging the beds of the brooks and rivers, or embanking the courſes of the ſtreams; theſe, with the moſt correct information that can be obtained from different millers and others, who live on the banks of the river, or from ſcientific individuals, who have cauſed accounts to be kept of the height of the water, will be neceſſary data for determining the magnitude and nature of the works which will be neceſſary on the propoſed navigation.

Mr. *William Chapman*, in his *Obſervations*, often before quoted, *page* 74, when treating of the canals of China, which are in effect but new channels for a part of the ſtreams of their rivers, takes occaſion to introduce ſome uſeful obſervations on the crookedneſs and unequal ſections of rivers, and on the effects of ſhallows, weeds, and other impediments, upon the velocity and height of the ſtream, that we muſt reluctantly for the preſent paſs over, referring the reader to our article River. As an inſtance of the fall and velocity of large natural rivers we are told, that the Ganges for 60 miles, having the mean width of 3-4ths of a mile, and depth of 15 to 20 feet, was found to have a fall, in a direct line, through the immenſe flats and rice-fields on its ſide, of 9 inches in a mile, but by following all the bends of the river's courſe, the fall was reduced to 4 inches per mile, and its velocity therein did not exceed 3 miles per hour. On aſcertaining readily the velocity of ſtreams of water, and comparing the ſame with theory, ſee *Nicholſon's Journal*, 8vo. vol. iii. p. 32 and 87.

Mr. *William Chapman* ſeems to incline to the opinion, that locks may not always be eligible on river-navigations, and ſays (p. 87,) that “ during the flooded ſtate of rivers, all ſmall falls are equalized, as they neceſſarily riſe higher below than above a rapid; therefore I am far from ſaying, that running canals with a ſmall fall are not, in many inſtances, eligible on the ſhores of great rivers; and that well deviſed ſtops, eaſily opened and cloſed, (not ſuch as lift up like thoſe deſcribed in China, nor open againſt the ſtream as gates,) are not ſometimes preferable, to incurring the charge of locks. In other nearly ſimilar inſtances where locks are eligible, their piers and gates alone, will be ſufficient without any other floor or ſide walls, than a concave and battered pavement, continued through the bottom and up the ſides of the ſpace between the piers. The eligibility, and the particular conſtruction of theſe works, will much depend on the nature and extent of the beds of the rivers, the difference between their low and flooded ſtates, the height and alſo the permanency of their ſhores, and the quantity of floating ice.

The greater number of rivers through which new navigations are now required to paſs, will be found occupied by mills, at ſhorter or longer diſtances from each other, according to the fall of the water in moſt inſtances; at the tail of moſt of ſuch mills, will be found a large and deep pool, which the fall of water from the mill-courſes and flood-gates has torn and excavated, and a ſhort diſtance below this pool a ſhoal or bed of gravel, or other matters, will in general be found, that would prove ſo expenſive to remove, and would in general be ſo ſubject to accumulate again by a further excavation of the pool from the increaſed fall of the water into it, that it will in general be the cheapeſt and moſt effectual way to begin a new cut for the navigation below this ſhoal, and continue the ſame up by the ſide of the pool to the bank of the mill, wherein a pound lock muſt be conſtructed, either of timber or maſonry, for gaining the aſcent to the mill-dam or upper pound. In rapid rivers ſubject to great floods, the utmoſt care and attention of the engineer to the conſtruction of ſuch works will be neceſſary, to prevent their being demoliſhed by the firſt flood perhaps after their erection. Where mills do not intervene, and rapid and of courſe ſhallow places occur in the bed of the river which is to be made navigable, a ſide-cut muſt be begun from above ſuch ſhallow, and if practicable at the beginning of a conſiderable bend of the river which the ſide-cut may cut off and ſhorten; in continuing this ſide-cut downwards towards the place where the lock is to be placed, and the junction below the ſame is to be formed with the river below the ſhallow, care muſt be taken to conduct the ſide-cut, which is to be upon a level as far as the lock, as ſoon as poſſible acroſs the flat meadows to the borders of the high ground, along which it ſhould ſkirt, to the place of the lock, if this is practicable, on account of the width of the meadows; otherwiſe a counter-drain or parallel cut muſt be taken up from below the lock, as far as is neceſſary, on the land ſide of the ſide-cut, to drain off the water, and prevent a ſwamp or pond being formed above the lock and between the ſide-cut and the high ground, as is almoſt invariably done by the ancient mill dams on moſt rivers and ſtreams: it is, however, with the utmoſt care and precautions that the counter-drain ſhould be adopted, otherwiſe, in time of floods, when the meadows are overflowed, ſuch a current would ruſh into and down the declivity of the counter-drain as to endanger the tearing thereof, and of the bottom and ſides of the cut or bed of the river, into which it vented below the lock. We have ſeen large and expenſive ſluices erected upon and near to the vent of counter-drains circumſtanced as above, of greater height than the top of the floods, which were found neceſſary to be built, and kept ſhut on the approach of a flood to prevent the action of the counter-drain, until the flood had ſubſided ſo far as not to overflow the meadows adjoining the counter-drain. Acroſs the bed of the river at the moſt convenient place below and near the upper end of the ſide-cut, an opening-weir muſt be conſtructed, by which the water in the river can always be kept at a proper height for covering the ſhallows and bed of the river to a proper depth for the navigation; ſeveral of theſe opening-weirs have within theſe few years been conſtructed on the *Thames*, one of which near Windſor has been deſcribed and drawn by Mr. *Zach. Allnutt* in his *Conſiderations on the beſt Mode of improving the River Thames*, 1805, p. 22. It conſiſts of ſeveral ſtrong piles or poſts driven firmly into the bed of the river at 20 to 25 feet apart, in a ſtraight line acroſs the river: the intervals between theſe piles are driven and nicely filled up with pug-piles, or dove-tail piles, as before deſcribed in this article; theſe laſt are afterwards ſawed off ſtraight and even with the bottom of the river, and have a ſtrong and ſound ſill nicely fitted and ſpiked on to them, and into each of the large piles at its end; by this means the water is prevented from ſoaking or making its way, except through the rectangular openings between the ſeveral piles, which ſhould be at leaſt as high as the higheſt floods, and have their tops connected by ſtrong croſs pieces of timber bolted on to them; in theſe croſs pieces, and in the ſill below, a number of holes are prepared for placing at equal intervals as many upright pieces of wood, called rimers, with rebates in their ſides, for temporary gates to ſlide down in, and reſt againſt; after theſe rimers are put in, a ſluice or gate, with a tall handle to reſt againſt the upper, or croſs piece, is put in between each rimer; and, above theſe, another ſet of gates, called overfalls, with ſimilar handles, are fitted, to be occaſionally uſed in dry ſeaſons, when none of the water is to be ſuffered to eſcape, except by the ſide-cut and lock-paddles. In time of floods, all theſe gates, overfalls, and rimers, are taken away, by perſons who go in a boat for that purpoſe; which operation, we are told, can be performed in three hours, and the water is ſuffered to take its free courſe through the openings: as the water ſubſides, a few of theſe gates are put in at a time, leaving the water its courſe through the others, until all of them are in, when on any ſmall riſe of the water, the ſame falls over the tops of theſe gates into the bed of the river below; when a greater depth of water is wanted above, the overfalls or upper gates are ſucceſſively put in upon the others; theſe laſt being of ſuch a height that the water can fall over their tops before it would overflow the meadows in caſe of its riſing, and the men not attending or being expeditious enough in taking away the overfalls, and then the gates, if the progreſſive riſe of the river ſhould render it neceſſary. Mr. *J. Plymley* in his report before quoted, page 316, has given a plate of a weir of this ſort for a river, which is called a gate-ſluice, with 17 gates, but we have looked in vain for any deſcription or account thereof in his volume. In the *Thames* and ſeveral other rivers, *Jetties*, or *Weir-hedges* have formerly been made, for diminiſhing the width of the river below the ſeveral ſhoals, in order to make a deeper but narrower and more rapid current over the ſame, as is done, we are told, on the China canals; but the rapid and dangerous currents which theſe and the underwater weirs occaſion, particularly in high water times, have been ſo juſtly and loudly complained of, that we truſt the ſame will, ere long, give place to the ſide-cuts, pound-locks, and opening-weirs, above deſcribed. The principles on which jetties are made to raiſe the water in rivers, and the mode of calculating their effects may be found in *Nicholſon*'s *Journal*, 8vo. vol. iii. p. 35.

For improving the navigation of rapid, confined, and variable rivers, like the *Severn*, Mr. *Thomas Telford*, in *Plymley*'s *Report*, p. 287, has recommended the deepening of the lower part of the bed of the river in the ſhallow places, in order to equalize the declivity and current of the river: a very experienced engineer has ſuggeſted, that deepened ſhallows, without jetties or ſimilar conſtructions, would ſoon be again filled up in many caſes. In the higher parts, Mr. *T.* propoſes to erect ſolid and durable weirs of maſonry acroſs the river upon the ſhallow places, with ſide-cuts and pound-locks by the ſide of them, for the navigation; and the river when thus diverted, may, as he juſtly obſerves, be applied to many important purpoſes of machinery, and for irrigating of the meadows, which would thus be brought within its reach. There is no doubt but this method is practicable, and would ultimately anſwer well; but the expence would be very great of erecting ſubſtantial weirs, and making the banks of the ſide-cuts, and walls, and gates of the locks, high enough to prevent the floods from breaking over into them, a condition which ſeems neceſſary, if barges are to be able to proceed at all times; the towing-path ſhould alſo for the ſame purpoſe be made up with a regular ſloping bank next the river, preſenting no inequalities or projecting objects to catch or wear the towing-lines, ſo that its top or path ſhall be always above water. On a river which riſes 16 or 17 feet or more, theſe works would be attended with a moſt ſerious expence and difficulty, particularly where cliffs riſe almoſt perpendicularly up from the bed of the ſtream. Machinery on ſuch a ſtream, unleſs great expence indeed was incurred to obviate it, would be ſubject to have its work interrupted by every large flood: the working of barges on a river with ſuch cuts, locks, and towing-paths, as we have mentioned, would be attended with conſiderable difficulties; tall maſts muſt be uſed for attaching the towing-line in dry-times to bring the line on a level, or nearly with the horſes, and in floods it muſt be fixed lower down, or to a ſhorter maſt: and, in ſuch caſes, the utmoſt care might not always be able, where the works are neceſſarily confined by rocky banks, to prevent barges from ſometimes miſſing the entrance of the ſide-cut, and being precipitated down the current over the weir, and being ſunk. A towing-path, locks and banks of a leſs height, ſo that the floods would frequently cover them, beſides their being totally uſeleſs in ſuch times, would be liable to be damaged and waſhed away, (unleſs conſtructed in the moſt careful and expenſive manner,) and the cuts and locks to be filled up in a great meaſure by ſand, or gravel, in rapid rivers. Mr. *William Reynolds* ſet an example which has ſince been followed, on a great length of the *Severn*'s bank, of conſtructing a towing-path for horſes, inſtead of the devious way over projecting rocks, looſe ſands, mud, and every other obſtacle which the men who uſed, from time immemorial, to perform the ſlave-like office of hauling the barges along, were obliged to travel: we are not acquainted with the height of theſe new towing-paths, or whether they are at times, and how frequently, covered and uſeleſs by reaſon of the floods. Mr. *Allnutt* informs us, that one horſe commonly tows a barge of 130 tons burthen down the *Thames* above Richmond, at the rate of two and an half miles per hour. While on the running canals of China, *ſir George Staunton* obſerved a boat of a light conſtruction, with only 14 tons lading, of eight feet width of floor, about 10 feet width of water-line, and 50 of extreme length, drawing two feet three inches of water, and ſharp at the ends, dragged againſt a ſtream whoſe velocity was 5½ Engliſh miles per hour; and, although there were 28 trackers, or men hauling at the line faſtened to the boat, beſides three men in the boat poling it on, it advanced only at the rate of ¼ of a mile an hour; although the channel was not materially conſtructed in either width or depth of water-way, in proportion to the ſection of the boat. Mr. *Thomas Telford* has (p. 288.) propoſed another method of improving the *Severn* river, by collecting "the flood waters into reſervoirs, the principal ones to be formed among the hills in Montgomeryſhire, and the inferior ones in ſuch convenient places as might be found in the dingles, &c. along the banks of the river. By this means, the impetuoſity of the floods might be greatly leſſened, and a ſufficient quantity of water preſerved to regulate the navigation of the river in dry ſeaſons, and likewiſe to anſwer many other uſeful purpoſes, ſuch as the forming ponds for inland fiſheries, the ſupplying of artificial canals, and the watering of land. This, it is thought, might even prove the ſimpleſt and leaſt expenſive mode of regulating navigable rivers, eſpecially ſuch as are immediately on the borders of hilly countries." An engineer of the firſt reputation in his profeſſion (Mr. *Rennie*,) intimates, that after what has been ſaid reſpecting the exceſs of flood water in the river Roch above the ordinary ſupply, the idea of correcting the floods of the *Severn* by reſervoirs, muſt appear to be ridiculous. Mr. *William Jeſſop*, on another occaſion already referred to, ſays, that the rivers may be rendered nearly uniform throughout the year by reſervoirs.

The old clumſy ſtone or brick bridges upon rivers are a very principal interruption to the navigation thereon, by preventing the continuation of the towing-path in a place where it is generally the moſt wanted to ſurmount the rapid fall occaſioned by the contracted water-way under the bridge; the maſts of veſſels are alſo obliged to be ſtruck. Theſe circumſtances recommend the more general imitation of the ſpirited individuals near Coalbrook-dale, who have there erected two caſt-iron bridges over the *Severn*, whoſe ſingle and capacious arches remedy theſe evils. We have already ſpoken of them under the article Bridge, and in the preſent one, and therefore proceed to the only remaining ſubjects that at preſent occur to us, relating to the deepening of rivers: the *heaving of ballaſt*, or taking up of ſand, gravel, or other looſe or ſoft matters from the bottom of rivers, is uſually performed by a ſtrong pole, having a flat ring or hoop of iron fixed on its end, to which a ſtrong leathern bag is faſtened, like what is called a landing-net among fiſhermen; or for taking up gravel only, a fine and ſtrong net is uſed inſtead of the leathern bag; the edge of this hoop is made ſharp, ſo as to ſtrike into the bottom, when a man puſhes it down by its pole; near to this hoop a rope of conſiderable length is faſtened, which is held by a man that ſtands at the head on the gunwale of a barge at anchor, while another man at the ſtern ſtrikes the hoop and bag into the bottom, the man at the head then hauls at the rope to drag the bag along and ſcrape the bottom, while the other man ſhoves down the pole to which it is attached, until the bag is filled with ſand, gravel, or other matters, which are wanted to be got up; the man with the rope then advances nearer to the other, and pulls up by the rope while the other does the ſame by the pole, and brings the bag over the ſide of the veſſel, and empties its contents into the hold or room of the barge. If the bottom be hard, or the bag large, two or more men are employed to pull the rope, and ſometimes a winch and roll on which the rope or chain winds, are uſed for dragging the hoop and bag along the bottom, and for hauling the ſame up to the ſurface, when the man at the pole finds that the bag is full, and begins to pull inſtead of puſh by the pole: this is the employment at Woolwich of a great number of convicts, inſtead of their being tranſported. Solid matters or rocks when they happen to want excavating, below the level that the water can be drawn off to, or the ebb of the tide, ſeem to require all the ſkill and reſources of the engineer. Near to the entrance of the new *Eaſt India Docks*, in the way of ſhips in the river *Thames* at Blackwall, is a rock or large ſtone of exceedingly hard ſilecious pudding-ſtone, conſiſting, as we have been informed, of the hard ſmall chert pebbles which abound ſo much near London, embedded in a cement ſtill harder than themſelves; detached blocks of which pudding-ſtone are by no means uncommon in the London *ſtrata*; this rock is ſo hard that no tool is capable of boring it, and though for ſome years paſt the committee for improving the port of London have been occaſionally advertiſing for perſons who were willing to undertake or contract for removing the upper part of this rock, about 40 feet in length and 30 in breadth to the depth of about 18 feet, yet the rock ſtill remains. The conduct of this buſineſs is now, it is ſaid, committed to Mr. *Jeſſop*, an able engineer; and we hope ſoon to hear of this dangerous impediment being effectually removed.

Having now given the principles and practice of canal-making, and of river-navigations and rail-ways, as forming one great, compound, and connected *Syſtem of Inland Communication*, we now proceed to give a conciſe account of all the different eſtabliſhments of this kind in the United Kingdoms. This part of the preſent article, although far ſhort of the degree of perfection which we were deſirous of giving it, has been attended with great labour, in reſearch for the ſcattered, and often ſcanty materials, that are to be found reſpecting many of theſe undertakings, which will ever remain as ſtupendous monuments of Britiſh enterprize and ſpirited exertion.

Reſpecting the method of arrangement, we found it inexpedient to follow thoſe who have attempted to give an account of ſome of theſe concerns, in the order of time in which they were projected or begun; becauſe ſo many of them, in diſtant places, were projected at the ſame periods, while ſome were quickly begun and completed, and others remained a great while in hand.

The great length of ſome of theſe works or undertakings, the ſhortneſs of others, their various directions and their general and multiplied interſections with each other, rendered any geographical arrangement of them, as from north to ſouth, or otherwiſe, equally difficult and improper. We truſt, therefore, that our readers will approve of the plan which we have adopted, of giving the whole of theſe undertakings, rivers, canals, rail-ways, &c. in one alphabetical ſeries, arranged according to the *incorporate, or parliamentary name* of each, where the ſame are under ſpecial acts of parliament. And, as many important lines of canal have been ſurveyed and deſcribed, but never ſince were executed, we have thought it right to preſerve the memory of many of ſuch, by giving them a place in the regular ſeries, but printing their titles in Italics, to diſtinguiſh them from the works exiſting or now proceeding with, which will be printed in ſmall capitals. Our principal aim has been to exhibit, as conciſely as poſſible, the principal features of each concern, and to trace its connecting points with all the other adjoining ones; by the help of which, it is hoped that our readers may be able to trace out and comprehend this great and unparalleled ſyſtem of improved inland communication, which has, and will continue to operate ſo powerfully towards our national proſperity.

Aberdare Canal. This undertaking was begun under an act of the 33d of Geo. III.; its general direction (beginning at its loweſt end, as we ſhall always do in theſe deſcriptions) is about N.W.; it is $7\frac{1}{2}$ miles in length to Aberdare, beſides an extenſion thence, in nearly the ſame direction, by a *rail-way* for $8\frac{1}{2}$ miles further; it is ſituate in the county of Glamorgan in South Wales, and is not far from the ſea-coaſt, or very greatly elevated above the ſame. The great coal and iron mines, and works near Aberdare, Furno-Vaughan, &c. ſeem its principal objects. It begins in the *Glamorganſhire* canal near Eglwyſila, and terminates in the *Neath* canal at Abernant. The firſt $4\frac{1}{2}$ miles of the canal are level, and thence it riſes 40 feet to Aberdare. Mr. *Thomas Dadford*, jun. is the engineer. A lock of ſufficient height, with proper ſide-weirs, was made near the lower end, to prevent the *Glamorganſhire* canal from ſuffering by floods, that may make their way into and through this canal. The company may raiſe 33,500l. ſhares, 100l. each. The rates of tonnage are too long for ſuch an abridged account as this; they will be found in *Phillip's 4to. Hiſtory of Inland Navigation, Appendix*, p. 38. Boats 12 feet long and 5 feet wide may be uſed, free of toll on the pounds, by the adjoining occupiers, for their huſbandry purpoſes. At Aberdare works are ſome curious machines; one is ſaid to be a pair of water-wheels, working one below the other like a figure of 8.

Aberdeenshire Canal. Acts 36 and 41 of Geo. III.— The general direction is about N.W. for 19 miles in length, in Aberdeen county in Scotland; it is near the ſea-coaſt, and is not greatly elevated in any part; the principal objects ſeem the ſupply of the town Aberdeen, the exportation of granite ſtone from the famous quarries on its banks, and to form a communication between the harbour of Aberdeen and the vales of the river Don. It begins in the tide-way in the *Dee* river in Aberdeen harbour, and follows the courſe nearly of the Don river, in which it terminates at Inverury bridge; and paſſes the pariſhes of Old Machar, Newhills, Dyce, Kinnellar and Kintoſe.

toſe. The riſe is 170 feet by 17 locks; the width of the canal is 20 feet, and depth of water $3\frac{1}{2}$ feet. The harbour of Aberdeen, (connecting with the *Dee* river near its mouth, at the S. E. end of this canal), was ſurveyed many years ago by Mr. *John Smeaton*, and lately by Mr. *Thomas Telford*, who has, in his reports to parliament, recommended making it capable of receiving ſhips of 18 or 20 feet draught of water. It appears that this canal was completed and opened in June 1805. The company might by the firſt act raiſe 30,000l., ſhares 50l. each; and by the 2d act 20,000l. more might be raiſed on 20l. ſhares, bearing 5 per cent. intereſt. Half-mile ſtones to be erected. Pleaſure-boats of twelve feet long, and four broad may be uſed on the pounds.

**ADUR RIVER.** The general direction of this river is nearly north for 12 miles in the county of Suſſex: its objects are the import of coals, deals, &c., and the export of farming produce. New Shoreham and Steyning are conſiderable towns on or near it. It commences in the ſea at Southwick below Shoreham harbour, and terminates at Bines-bridge in Weſt-Grinſted. In September 1805, notices were given of the application for an act for extending this navigation from Bineſbridge to Baybridge in Shipley.

*Alford and Wainfleet.* In July laſt (1805) a ſurvey was ordered for an intended canal from Wainfleet haven to the town of Alford, the general direction of which line is nearly north, and about 12 or 13 miles in length, in the county of Lincoln: this line is near the coaſt, and ſeems but very little elevated above the ſea: its principal objects ſeem the ſupply of Alford, and the export of huſbandry produce: it is propoſed to paſs the town of Burgh. Wainfleet haven is ſaid to be a very good harbour for trading ſhips.

**ANCHOLME NAVIGATION.** Act 42 of Geo. III.—The general direction of this navigation is nearly ſouth: it is almoſt ſtraight (except the laſt four miles), and about 26 miles in length, in Lincolnſhire. It is ſituate within 15 or 20 miles of the coaſt, and runs nearly parallel thereto through fens and level grounds for great part of its length. Its objects, beſides a better drainage of theſe fens by a wide and ſtraight cut, inſtead of the old courſe of the river Ancholme, ſeems the ſupply of Market-Raiſin and of Caiſtor (by means of the *Caiſtor* canal, which joins it at South Kelſey), and the export of huſbandry produce. It begins in the tide-way in the *Humber* river near Wintringham, and extends to the town of Market-Raiſin, paſſing near the town of Brigg.

**ANDOVER CANAL.** Act about the 30th of Geo. III. Its general direction is nearly north, and pretty ſtraight, following the courſe nearly of the *Anton* river (which is navigable to Rumſey) for $22\frac{1}{2}$ miles in length, in Hampſhire; it is near the coaſt, and not very greatly elevated in any part above the level of the ſea. Its general objects ſeem to ſupply fuel to the country, and to export its ſurplus of farming produce. It connects with the *Southampton and Saliſbury* canal, the latter entering it at Red-bridge, and leaving it again at Kimbridge mill. The town of Southampton, near its ſouth end, is the 68th in the order of Britiſh population, having 7,913 inhabitants. This canal begins in the tide-way in *Southampton-water* at Redbridge, and terminates at Barlow's mill near the town of Andover; the towns of Rumſey and Stockbridge being on its courſe. Its riſe is equal to $176\frac{1}{4}$ feet, and it is fed at its upper end from Pilhill brook. This line was ſurveyed by Mr. *James Brindley* in the year 1770, and an act propoſed, but the oppoſition of the land-owners prevented one being obtained, until it had been again ſurveyed in 1789, by Mr. *Robert Whitworth*; in a few years after which it was completed for uſe.

*Arklow and Ovoca.* In 1792, Mr. *William Chapman* ſurveyed the vales of the Ovoca river in Ireland, and recommended to render the improvement of Arklow harbour, which was then intended, more beneficial to the adjacent country, by connecting therewith a ſyſtem of ſmall canals up the rapidly aſcending vales of the Ovoca, by riſing 70 or 80 feet at once in proper places, by ſome of the ſubſtitutes for locks, of which we have before ſpoken.

**ARUN RIVER.** This navigation has nearly a north direction for 15 or 16 miles in the county of Suſſex. To ſupply coals, and export farm produce, ſeem its principal objects; which are facilitated by the *Arundel* canal, that joins it near Stopham bridge, and would be further accompliſhed, were the *Surry iron rail-way* extended to it at Wiſborough-green bridge, as was propoſed in the year 1801. It proceeds from the ſea at Arundel haven to Wiſborough-green bridge, paſſing the town of Arundel in its courſe.

**ARUNDEL CANAL.** Act 31 of Geo. III.—The general direction is weſt for about 11 miles, following the courſe of the river Rother, in the county of Suſſex. It is about 12 or 13 miles from, and nearly parallel to, the ſea-coaſt, above which it is but little elevated. The ſupplying of the inhabitants with coals, and exporting of huſbandry produce, ſeem the principal objects of this canal. It commences in the *Arun* river near Stopham bridge, and terminates at the lower plat near Midhurſt, with a ſide cut of about one mile in length to Haſlingbourn bridge in Petworth pariſh. The line being through the pariſhes of Stopham, Coldwaltham, Bury, Fittleworth, Ergdean, Coates, Sutton, Petworth, Duncton, Burton, Tillington, Lodſworth, Selham, Amberſham, Eaſebourn, Woolavington, and Midhurſt. This canal is the property of that public ſpirited nobleman the *earl of Egremont*, but open to the uſe of the public, on paying certain ſpecified tolls.

**ASHBY DE LA ZOUCH CANAL.** Act 34, Geo. III.—The general direction of this canal, though in a ſerpentine courſe, is nearly north, 40 miles in the counties of Warwick, Leiceſter, and Derby. It commences near and almoſt upon the grand-ridge on its eaſtern ſide, and near its other extremity is tunnelled through a yet higher ſide-branch of the great ridge. The conveying away of the coals and lime-ſtone from this laſt ridge, and the ſupply of the towns on its borders by means of the *Coventry* canal, with which it connects, are its principal objects. Coventry, which is near it, is the 24th town for population in Britain, having 16,034 inhabitants; while Hinckley, which is upon the line, has 5,070 perſons, and is the 120th in order. Market Boſworth and Aſhby-de-la-Zouch are other conſiderable towns near or on the line; the commencement of which is at Marſton bridge near Nuneaton, on the *Coventry* canal, and the termination is by a *rail-way* (of $3\frac{3}{8}$ miles) at Ticknal lime-works; there alſo is a *rail-way* branch of $6\frac{3}{4}$ miles to Cloudſhill lime-work; another to Mr. *Wilke*'s Meaſham collieries of 5 miles: a cut of $2\frac{1}{8}$ miles to Swadlingcote coal-works; another of $\frac{7}{8}$ mile to Staunton lime-works; another is to be made to Stanton-Harrold park (if deſired by the *earl of Ferrers*, the proprietor thereof); and there is another ſhort cut of 200 yards to Hinckley wharf. The firſt $30\frac{3}{8}$ miles of this canal are level, extending to Oakthorpe engine on Aſhbywoulds; and forming with parts of the *Coventry* and *Oxford* canals, a level of 73 miles in length, being, without the branches, the longeſt in the United Kingdoms, and rendered more ſingular by being on ſo high a level, as to croſs the grand ridge without a tunnel. From Oakthorpe engine to the Boothorpe feeder, 1¾ mile, is a riſe of 140 feet, thence the ſummit-level of 4¼ miles extends, through the principal tunnel to its north end; thence to the Cloudſhill branch, ¼ of a mile, is a fall of 84 feet, and thence to Ticknal works is it level. The Cloudſhill, Swadlingcote, and Hinckley branches, are level with the line, and the Staunton branch falls 28 feet therefrom. On this canal are two tunnels, one near Aſhby-de-la-Zouch town of 700 yards in length, and the other near Snareton of 200 yards. At Shackerton and at Snareton there are aqueducts; and at Boothorpe a reſervoir with a ſteam-engine for pumping up its water into a feeder for the ſummit-level of the canal. The rail-way branches, and ſome part of the canal were completed previouſly to May 1802, but it was not until about May 1805, that the whole of the line was completed and opened. The company were authoriſed to raiſe 200,000l., the amount of ſhares 100l. each. Public wharfs are provided on Aſhby woulds, and at Green-hills near Sutton Cheney. Sir *George Beaumont*, the owner of collieries at Coal-Orton, to which rail-ways had previouſly been made at great expence connecting with the *Leiceſter* navigation, is to be compenſated, and the company may purchaſe certain annual quantities of his coals for ſuch purpoſe. This company is alſo bound to indemnify the *Leiceſter* navigation, and to allow them a rate of 2s. 6d. per ton on all coals carried upon this canal or its branches beyond a certain point from the coal-pits in the neighbourhood of their water-levels or rail-ways. To the *Coventry* canal company they are alſo bound to pay 5d. per ton for all coals, and ſome few other articles, which paſs upon any part of this canal or its branches, and afterwards upon any parts of the *Coventry*, the *Oxford*, or *Grand Junction* canals, or from either of thoſe canals to this: and for duly enforcing this laſt compenſation, the *Coventry* company are authoriſed to erect toll-houſe and bars, and ſtation their own collectors when and where they may chuſe upon the works belonging to this company. The rates of tonnage allowed, vary from 2d. to ¾d. per ton per mile on different goods, while ſome articles are to be allowed to paſs toll free. Our limits will not allow of ſtating theſe particulars, which will be found in *Phillips's Hiſtory of Inland Navigation*, 4to. *Appendix*, p. 128. In June 1796, a ſurvey was made by Mr. *Whitworth* for connecting the north end of this canal, by means of the propoſed *Commercial* canal, with the *Trent and Merſey* and the *Cheſter* canals, and opening the long wiſhed for communication between London, Hull, Cheſter, Liverpool, Mancheſter, &c. for river-boats of 40 tons burthen. In conſequence of the failure of this ſcheme, in the January following, it was propoſed to extend this canal to the *Trent* at Burton, and to the *Trent and Merſey* at Shobnall.

Avon River, (*Bath.*) The general direction of this navigation is about S. E., in length 26 or 27 miles, by a crooked courſe in the county of Somerſet, and ſkirting that of Glouceſter: it opens into the *Severn* river, and is moſt of it a tide-way. The objects of this navigation are as various, as the imports and exports of ſuch large places as Bath and Briſtol, and a populous neighhourhood require; beſides its connection with the *Kennet and Avon* canal, and the other canals therewith connected. The city of Briſtol is the 7th place in the order of Britiſh population, having 68,645 inhabitants, and Bath is the 12th, with 32,200 inhabitants. The commencement of this river is in the King's road in the *Severn* river (here about ſeven miles wide), and its navigation ends at Bath, near the commencement of the *Kennet and Avon* canal. About the year 1803, or 1804, an act was obtained by the *Briſtol Dock* company, for converting about 70 acres of the old and crooked courſe of the *Avon* into a vaſt floating-dock for ſhips, and to cut a new channel for the river. About May 1804, theſe works commenced, under Mr. *W. Jeſſop*, and great progreſs has been made towards their completion. Two caſt-iron bridges are erecting over the *Avon* near theſe works; one of them from Clifton-down to Leigh-down will, it is ſaid, be 200 feet high above the ſurface of the water, and the other ſufficiently high for ſhips to paſs under it. That eſſential appendage, a towing-path, was wanting on this river, until the above company was eſtabliſhed, who are making one on each ſide of the river, from Pill up to Briſtol, and one thence to Hanham mills; from which place up to Bath, a towing-path is propoſed to be extended, under an act, for which notices have juſt been given; this laſt part of the river is alſo intended to be improved in other reſpects. We have, alſo, lately ſeen a notice for a further application to parliament by the *Briſtol Dock* company, for erecting a dam and overfall, with ſluices, &c. at Red-cliff in Bedminſter, to keep up the water for the new floating docks, and for other amendments of their former acts; in 1796 it was propoſed that the *Kennet and Avon* canal ſhould be extended to this river at Briſtol. At Bitton below Bath, it was lately propoſed, that the *Glouceſterſhire* rail-way ſhould connect. In 1762, Mr. *Stratford* gave a deſign for a new ſtone bridge in Briſtol of one arch, 150 feet ſpan, and 32½ feet high, which Mr. *John Smeaton* examined and approved; and in 1765, the laſt mentioned engineer gave a deſign and eſtimate for a floating dock nearly as above; after which, Mr. *Campion* made other deſigns.

Avon River, (*Saliſbury.*) The direction of this navigable river is very nearly north, and its length near 30 miles, in the counties of Hants and Wilts. The general objects of this navigation are the ſupply of Saliſbury, and the adjacent country, and the export of its agriculture products. Near Saliſbury, it connects with the *Southampton and Saliſbury* canal. Saliſbury contains 7,668 inhabitants, and is the 70th place in the order of our population; Fording-bridge, Ringwood, and Chriſt-Church, are likewiſe conſiderable towns on the line. The commencement is at the ſea in Chriſt-Church harbour, and termination at Saliſbury. The locks and works of this navigation had not been long completed, before a ſudden flood happened, which ſwept away the greater part of them; in which ſtate it lay until 1771, when Mr. *James Brindley* ſurveyed its courſe, and recommended a new canal by the ſide of the river; this was not however adopted, but the river-works have ſince been repaired; and the imperfection of them, was, we believe, among the moſt powerful motives for the adoption, in 1795, of the *Southampton and Saliſbury* canal above mentioned. Mr. *Smeaton* examined Chriſtchurch harbour in 1764, and recommended another pier to be built weſt of the old one.

Avon River, (*Stratford.*) The general direction of this navigation is about N. E. by a crooked courſe of near 40 miles in Worceſterſhire and Warwickſhire: the lower end thereof is but a few feet higher than the tide-way. The trade thereon is very various, depending in a great meaſure on the connection which it forms between the *Severn* river and the *Stratford* canal. Tewkſbury, Perſhore, Eveſham, and Stratford, are conſiderable towns upon it. It commences in the river *Severn* at Tewkſbury, and terminates at Stratford on Avon, near the junction of the *Stratford* canal. *George Perrot*, eſq. is the proprietor of this navigation, and entitled to certain tolls, which were not to be leſſened by the new communication with the *Severn*, which the *Worceſter and Birmingham* and *Stratford* canals were to open, but they were, by the act for the latter concern (33 Geo. III.), to make good any falling off in theſe tolls. About 1792, the *Stratford and Croperdy* was propoſed to proceed from this river at Stratford to the *Oxford* canal.

Axe River. The general direction of this navigation is almoſt S. E. for about 11 miles in length by a crooked courſe in the county of Somerſet: it is but little elevated. Its chief objects are the import of coals, and export of farm produce, Axbridge being the only town of any importance upon it. It commences in the Briſtol channel near Uphill, and terminates near Axbridge. An act of the 42d Geo. III. paſſed, for altering and improving that part of it which is between Bleydon and Axbridge. At Blean the *Briſtol and Taunton* canal was once propoſed to join this navigation; as the *Exeter and Uphill* alſo was deſigned to do at Uphill.

*Axemouth and Langport.* In 1769, Mr. *James Brindley* ſurveyed this line, which is nearly north, and about 30 miles in length, in Devonſhire, Dorſetſhire, and Somerſetſhire, croſſing the ſouth-weſtern branch of the grand ridge. The objects of it ſeem to have been the ſupply of coals, exporting the products of the country, and opening a communication between the ſouth coaſt and the Briſtol channel, by means of the *Parret* river. Axminſter, Chard, and Ilminſter are the principal towns which this line was to approach; commencing in the tide-way at Axemouth, and terminating in the *Parret* river at Langport.

Ayre and Calder Navigation. Act 9 or 10 of Will. III. The general direction of the *Ayre* river is nearly weſt, for about 40 miles by a ſerpentine courſe, from which the loweſt part of the *Calder* river branches, nearly ſouth-weſt, by a crooked courſe of about 15 miles, all in the Weſt Riding of Yorkſhire. The firſt of theſe rivers, though an internal one, begins near the level of the tide-way, and no parts of either of the navigations thereon are much elevated. The objects of this navigation were at firſt very conſiderable, in the imports and exports of the populous, manufacturing, and coal country through which it paſſes, and they are greatly increaſed, ſince it has formed part of the grand communications between the port of Hull, or the German Ocean, and the towns of Mancheſter and Liverpool, or the Iriſh Sea, by means of the *Leeds and Liverpool*, *Rochdale*, and *Huddersfield* canals, and others joining them. It connects near Snaith with a branch of the *Don* or Dun river; at Leeds, with ſome conſiderable *rail ways* extending to collieries from the coal-ſtaith; near Wakefield it connects with the *Barnſley* canal. Leeds is the 8th place in point of population in Britain, having 53,162 perſons, and Wakefield the 64th, with 8131 perſons; Hunſlet, near it, is the 104th, with 5799 perſons; Snaith, Selby, and Pontrefact, are alſo conſiderable places near this navigation, which begins in the *Ouſe* river near Armyn (to which place 50 and 60 ton ſloops come up), and terminates its north-weſtern branch at Leeds in the *Leeds and Liverpool* canal, and its ſouth-weſtern branch at Wakefield in the *Calder and Hebble* navigation. It has alſo a branch of canal about $4\frac{1}{2}$ miles to the *Ouſe* river at Selby, for ſhortening the diſtance to York, &c.; and another of $1\frac{1}{2}$ mile near Mathley, between the *Ayre* and *Calder* rivers, for ſhortening the voyage between Leeds and Wakefield. The boats generally uſed hereon are 56 feet long, $13\frac{1}{2}$ wide, and draw 3 feet water, with 28 tons of lading: theſe boats often go down the *Humber*, and round the coaſt, to the *Welland* and Great *Ouſe* rivers. The proprietors are authoriſed to exact ſo high a rate of tonnage as 16*s.* per ton in winter, and 10*s.* in ſummer, between Leeds and the *Ouſe*. It is provided in the *Huddersfield* act, 34 Geo. III., that if any communication is hereafter made with that canal to the eaſtward, the proprietors of this are to be compenſated. The oppoſition of theſe parties proved fatal, in 1769, to a canal which Mr. *Brindley* ſurveyed between *Selby and Leeds*.

Barnsley Canal. Act 33 of Geo. III. The firſt part of the courſe of this canal is ſouth, and the remainder weſt, about 15 miles in length, in the Weſt Riding of Yorkſhire: its weſtern end is conſiderably elevated above the level of the ſea. The principal objects of it ſeem to be the export of coals and paving-ſtones, and forming a ſhort communication with Rotherham and Sheffield (by the *Dearne and Dove* canal, with which it connects at Eyming wood near Barnſley), and Leeds, Wakefield, Halifax, Mancheſter, Liverpool, &c. Wakefield is the 64th town in the order of population, with 8131 perſons; Barnſley is alſo a conſiderable town. This canal commences in the lower part of the Calder river, or *Ayre and Calder* navigation, a little below Wakefield town, makes a turn when it arrives at the Dearne river, and terminates at Barnby-bridge near Cawthorn; there is a branch of $2\frac{1}{2}$ miles to Haigh-bridge in Wooley pariſh, and rail-way branches to Barnſley town 1 mile, and to Silkſtone $1\frac{1}{2}$ mile. From the *Calder* to the junction of the *Dearne and Dove* canal, about 9 miles, is a riſe of $120\frac{1}{3}$ feet: this is effected by three locks together, near Agbridge, having a low level or ſide-cut brought up to near the upper pound, with a ſteam-engine for pumping up the water again, which is let down by the lockage; by 13 other locks near Watton, and a long ſide-cut, from which engines pump up the water to ſupply the pound above theſe; and, near Bargh-bridge, by 4 other locks, a ſide-cut, and engine. On the Haigh-bridge branch there are alſo 7 locks together, with a low ſide-cut, and a ſteam-engine for pumping up the water required for lockage. At Eym is an aqueduct-bridge. This canal is adapted to the uſe of the ſame ſized boats as navigate the *Calder*. It is provided, that any rail-ways or ſtone-roads, that may be made northward from Barghbridge (or mill) ſhall be diſcontinued or removed, if a cut ſhall be made from the *Calder and Hebble* navigation, to connect herewith; alſo, that the ſteam-engine near Warmfield ſhall be ſo conſtructed as to burn its own ſmoke, to prevent any nuiſance to the inhabitants. The company were authoriſed to raiſe 97,000l., ſhares, 100l. each. This canal was completed and opened 8th of June 1799. The rates of tonnage on different articles are various: ſome fixed at 6d. to 4d. for the whole length of the canal; and various others at 3d. to $\frac{1}{2}$d. per ton per mile, with ſeveral exemptions, rates of wharfage, &c. See *Phillip's Hiſtory*, 4to. *App.* p. 40 to 43. The engineers were Mr. *William Jeſſop*, Mr. *William Wright*, and Mr. *Goll.*

Barrow River (*Ireland*). This is one of the rivers, for the improvement of whoſe navigation the Iriſh parliament granted ſeveral ſums of the public money, between the years 1753 and 1771, amounting to 13,600l. It is probable that leſs than the half of this amount, raiſed and expended by individual proprietors, with that circumſpection which ſelf-intereſt can alone inſpire, would have effected what, we are told, this expenditure has left very imperfect. At Portarlington and at Moneſteraven this river was to be joined by different branches of the *Grand Canal.*

Basingstoke Canal. This line of canal was firſt propoſed in 1772, as an extenſion of, or appendage to, the canal intended for ſhortening the courſe of the navigation of the river *Thames*, between *Reading and Maidenhead*; but it was ſome years before the firſt act for this was obtained, in 1778; the other act is the 33 of Geo. III. The general direction of this canal is nearly weſt, by rather a crooked courſe of 37 miles in length, in the counties of Surry and Hants; the ſummit-pound thereof of 22 miles in length is upon a high level, near the ſouth-eaſt branch of the grand-ridge on its north ſide. The principal objects thereof ſeem the import of of coals, and export of timber and agricultural produce, from and to the *Thames*. Baſingſtoke and Odiham are conſiderable towns on or near its line, which commences in the *Wey* river at Weſtley, (about two miles from its junction with the *Thames*,) and terminates at Baſingſtoke. A cut of 6 miles in length, and level with the ſummit-pound, was propoſed northward to Turgis Green, but has not yet been begun, as we underſtand. The firſt 15 miles from the *Wey* river has a riſe of 195 feet by 29 locks to Dadbrook, (the part at each lock being about 7 feet) from whence to Baſingſtoke it is level: 45 ton boats are uſed on this canal. At Grewel is a tunnel, part of which interſects the chalk ſtrata, (about $\frac{3}{4}$ mile in length) that had the misfortune of falling in; but the ſame has, we are told, been ſubſtantially repaired. At Alderſhot there is a large reſervoir for the ſupply of this canal, (which was begun in 1788 and completed in 1796, at the expence to the proprietors of 160,000l.) and a feeder from the river Lodden. There are 72 bridges over the canal, and ſeveral culverts acroſs, to convey the water from the upper to the lower lands. The company were authoriſed to raiſe 186,000l. The prices of freight from Baſingſtoke to Hamborough wharf, London, for coarſe and heavy goods, was, in 1800, 15s. per ton; to the dockyards, as far as Deptford, 16s.; and to Blackwall docks, 17s. per ton for timber, &c. The length of a paſſage is three or four days. In the year 1796 there was an intention of extending a branch from near Grewell tunnel, of about 22 miles in length, to the navigation that connects with *Southampton water*; about 1794 there was an expectation of its being joined by the canal which will next be mentioned; and in 1801, notices were given of an intended cut from Chilton-moor to Bagſhot-green in Windleſham; for want of theſe or ſome other junctions that ſhall throw a greater trade into it, this canal has, though improving, been as yet rather unproductive to the ſhare-holders. In 1800 there was a propoſal for extending the *Grand Surry* to meet this canal at the Wey river.

*Baſingſtoke and Hampſtead.* About the year 1794, a line of canal was projected, and notices given, extending from the *Baſingſtoke* canal at that town, to the *Kennet and Avon* canal at Hampſtead, 2 miles above Newbury, the length of the line was ſaid to be 22 miles; we have ſince heard nothing of this ſcheme.

BELFAST to LOCH NEAGH. This line of canal was begun under an act of the Iriſh parliament ſeveral years ago, for forming a communication with the ſea at Carrick-fergus Bay and the above inland lake or loch, as alſo for exporting marble from the quarries thereof near its line.

*Belper Canal.* In September 1801, notices were given for a propoſed canal, rail-ways, &c. from the *Cromford* canal at Bull-bridge, to Black-brook-bridge, through the pariſhes of Crick, Heage, Aſhley, Hay, Belper, and Duffield; all in Derbyſhire.

*Biggleſwade and Hertford.* Several years ago a propoſal was made, for joining the *Ivel* river at Biggleſwade with the *Lea* river at Hertford, by means of a canal paſſing the town of Hitchin, by which an internal communication between Lynn and London would be opened; but the difficulty of ſupplying a ſummit-level near Stevenage with water, ſeems a greater obſtacle than the expected trade would pay for ſurmounting.

BIRMINGHAM (*old*) CANAL. Acts the 8th, 9th, 11th, 23d, 24th, and 34th of Geo. III. the laſt but one of which acts, unites the concerns of this company with thoſe of the *Birmingham and Fazeley* canal below; but as theſe canals were conſtructed and remain under diſtinct proviſions in the acts, and take different directions from the town of Birmingham, where they meet, we have deviated from our uſual rule and continued them ſeparate in our account. The general direction of this canal is about S. E. and $22\frac{1}{2}$ miles in length by a crooked courſe, through the counties of Stafford, a detached part of Salop and Warwick: it ſkirts along near the grand-ridge on its eaſtern ſide, at ſo high a level as to croſs it near its northern end without any deep cutting or tunnel; and, in that high ſituation is wholly ſupplied by reſervoirs for flood waters, or ſteam engines which pump up the water again, after it has been let down for lockage, or out of old and diſuſed coal-pits. The principal objects of this canal are the carrying away of the coals from the numerous mines on its banks and branches, and the manufactured goods of Birmingham to Liverpool, Mancheſter, &c. It connects near Farmer's-bridge at Birmingham, with the *Worceſter and Birmingham*, at Tipton Green with the *Dudley* canal, and near Wolverhampton with the *Wyrley and Eſſington* canal. The great towns on and near the ſame are, Birmingham, the 6th in the order of population, containing 73,670 inhabitants: Wolverhampton, the 33d, with 12,565 perſons; Walſal, the 47th, with 10,399 perſons; Dudley, the 49th, with 10,107 perſons; and Bilſton, the 87th, with 6,914 perſons: in the centre of ſo large and active a population as this, the wonder in a great meaſure ceaſes, that this canal, conſtructed and carried on under ſuch peculiar diſadvantages, ſhould nevertheleſs have proved the moſt lucrative concern of the kind in the kingdom. This canal commences in the *Staffordſhire and Worceſterſhire* canal at Alderſley or Autherly, near Wolverhampton, and terminates in the *Birmingham and Fazeley* canal, at Farmer's-bridge, near the upper end of the town of Birmingham, the line being double in two places, viz. at Tipton, where a tunnel of near 1000 yards, and a canal of $1\frac{1}{8}$ mile in length, between Bloomfield and Deepfield has been made ſince 1794, for avoiding a zig-zag loop round Tipton hill, of 4 miles; alſo at the Smithwick locks, where two canals with 3 locks on each have been made, ſince 1787, for accommodating the immenſe traffic which is hourly paſſing. The collateral cuts are very numerous, the principal one extends from near Bromwich to the town of Walſal, by a crooked courſe of $8\frac{1}{4}$ miles; from this branch nine or more branches ſtrike off to as many coal-works, &c. on each ſide of it; the termination of ſome of theſe are, near Wedneſbury town, at Broad-water engine, Toll-end, Bradley, Bilſton, David's Ram-farm, and other coal-works: the lengths of all which are ſeveral miles. From the line there is alſo a cut of about one mile, to Oker-hill coal works; another to Meſſrs. *Bolton and Watt's* famous Soho foundery, and another to Newhall-ring baſon and wharf in Birmingham. In the firſt mile and three quarters, the riſe from the *Stafford and Worceſter* canal is 151 feet, by means of 20 locks, then $18\frac{1}{4}$ miles are level; a deſcent of 18 feet then takes place, by 3 locks (on each of the two branches before-mentioned); the remainder of the line about $4\frac{2}{3}$ miles is level, to the junctions of the *Birmingham and Fazeley* and the *Worceſter and Birmingham* canals at Farmer's bridge. The Walſal branch, where it leaves the line, has a fall of 18 feet by means of 3 locks, and about two miles further near Rider's-green, a further fall of 48 feet by 6 locks, whence to Walſal is level; the Toll-end branch has a riſe of 15 feet by 3 locks, and the Bradley of 20 feet by 4 locks, all the other cuts being level. This canal was originally cut 28 feet wide at top, 16 at bottom, and $4\frac{1}{2}$ deep; but by conſtant wear and widening it is now 40 feet wide at the top on the average. The locks are 70 feet long and 7 wide in the clear, and the boats carry about 22 tons. At the coal-wharf near Farmer's-bridge, and at its ſide cuts, 40 boats can unload at the ſame time; the Newhall-baſon of 2 acres, is for the unloading and loading of timber, ſtone, ſlates, and general merchandize, no wharfage is charged at either of theſe wharfs. Originally, there was a ſummit-level on the line of about one mile in length at Smithwick, 18 feet higher than at preſent, (of which 1000 yards was deep-cutting, 28 feet in the deepeſt part) and it was ſupplied until 1787, by a ſteam-engine at each end; when, owing to the increaſing trade, this ſummit was cut down, and 6 locks removed, making the deep-cutting one mile in length, and 46 feet deep in one place; and though this work was $2\frac{1}{2}$ years in hand, and coſt 30,000l. yet it was ſo managed, that the paſſage of boats was only 14 days interrupted thereby. There is a conſiderable reſervoir near Oldbury, and another near Smithwick, with feeders for conveying their waters into the ſummit level. The celebrated Mr. *James Brindley* was the original engineer, and on the 6th of November 1769, he completed 10 miles of the line and branches next Birmingham, by which coals were firſt brought by water to that great town from near Wedneſbury, and their price to the inhabitants was lowered at once from 15s. and 18s. to 7s. 6d. per ton! In October 1772, the line was opened, and in June 1799, the Walſal branch was completed. The proprietors were authoriſed to raiſe 115,000l. before the conſolidation of this and the *Birmingham and Fazely* concerns. At firſt the ſhares of this were 100l. each; but were by the ſecond act 9th Geo. III. reduced in number and made 110l. ſhares; thoſe created ſince the 24th Geo. III. are 170l. ſhares. The original tonnage on all goods, (excepting lime ſtone) was $1\frac{1}{2}$d. per ton per mile, and for lime-ſtone and lime, $\frac{1}{2}$d. per ton, except for manuring of the lands of the adjoining proprietors, and road materials were allowed to paſs toll-free; but the ſubſequent alterations in the ſeveral acts ſince would much exceed our limits to mention, thoſe who are deſirous of further information will find it in Mr. *John Cary's Inland Navigation*, 4to. pages 36 to 45. By the *Dudley* act, 25th Geo. III. this company are entitled to certain tolls on goods paſſing on or off of that canal to this; and, by the *Wyrley and Eſſington* act (32 Geo. III.) to other rates for the junction therewith; all which may be ſeen as above. About the year 1790, a cut was propoſed from this canal (inſtead of the Dudley junction) to Netherton collieries $12\frac{1}{2}$ miles, by a tunnel through the grand-ridge near Oldberry, of 2,078 yards, and 184 feet under the hill: in 1796, a foundery and large works belonging to Meſſrs. *Bolton and Watt*, were erected on the banks of this canal 5 miles from Soho. This canal extending acroſs a country full of coal, it was apprehended that the ſinking of the old pits might damage the ſame, and the company have power to enter and examine mines to prevent their working within 12 yards of the canal, except by paſſages of 4 feet wide, and 6 feet high: for want of more ſtrict attention to this, ſome of the branches near Wedneſbury have been undermined and broke in, ſo as to cauſe the canal to be abandoned in that part. From ſome of the old worn out coal-mine ſhafts near Bilſtone, a lambent blue flame ariſes in the night, of which a great deal has been ſaid and written. Proprietors of mines within 1000 yards of this canal, or its branches, may make *rail ways* thereto.

BIRMINGHAM AND FAZELEY CANAL. Acts 23d, 24th, 25th and 34th of Geo. III.; the ſecond of theſe acts is for conſolidating this concern with the old *Birmingham* above; but each part of the canal remains ſubject to its own original regulations, as above obſerved, and the laſt but one is for conſolidating $5\frac{1}{2}$ miles of the *Coventry* canal herewith, ſubject to the original powers of the *Coventry* act (8th Geo. III.) under which it was ſet out and made. The general direction of this canal is S. W. excluſive of the late Coventry part, which lies in a direction between N. and N.W. from the original termination at Fazeley: the length of the whole is $20\frac{1}{2}$ miles in the counties of Stafford and Warwick: the whole of this line of canal is conſiderably elevated, but particularly the S.W. end in the town of Birmingham, which is ſituate near the grand-ridge on its eaſtern ſide. The great objects of this canal are, the export of the manufactures of Birmingham towards London or Hull, and of coals; the ſupply of grain and other articles to Birmingham and its populous and buſy neighbourhood; it connects with the *Wyrley and Eſſington* canal near its commencement at Whittington-brook, with the *Coventry* at Fazeley, with the *Warwick and Birmingham* at Digbeth, and with the *Worceſter and Birmingham* canal near its termination at Farmer's-bridge. Birmingham, as before obſerved, is the 6th Britiſh town, with 73,670 inhabitants, and Tamworth near the line, is a conſiderable place. The commencement of this canal is in the detached part of the *Coventry* canal, at Whittington-brook, and its termination in the old *Birmingham* canal at Farmer's-bridge at the top of Birmingham town. From the N.E. entrance of the town of Birmingham, a branch ſkirts the town to the lower part of it called Digbeth, and there connects with the *Warwick and Birmingham* canal. From the detached part of *Coventry* canal at Whittington-brook, to its junction with the line of that canal at Fazeley, and thence paſt the ſmall aqueduct bridges near Middleton-hall, about $8\frac{1}{4}$ miles are level with the *Coventry* canal; from thence to the aqueduct bridge over the Tame river at Salford, $9\frac{3}{4}$ miles, has a riſe of 90 feet by 14 locks, thence to the Digbeth branch, near $1\frac{1}{2}$ mile, has a riſe of about 71 feet by 11 locks; thence to the old *Birmingham* canal at Farmer's-bridge, about $1\frac{1}{2}$ mile, is a riſe of about 85 feet by 13 locks; the Digbeth cut, of about $1\frac{3}{4}$ mile in length, has a fall of 40 feet, by 6 locks to the *Warwick and Birmingham* canal. The width of this canal is about 30 feet, and its depth $4\frac{1}{2}$ feet. The locks are 70 feet long and 7 wide in the clear, carrying boats with about 22 tons of lading. There are a wharf and baſon at Digbeth for the accommodation of the lower part of Birmingham. The Salford aqueduct bridge has 7 arches over the Tame river of 18 feet ſpan each. The Digbeth cut is tunnelled or rather arched over in the town of Birmingham; there is alſo a ſhort tunnel on the line where the Liverpool road croſſes. The *Coventry* company being unable for want of money to proceed with the eſſential part of their line, between Fazeley and Fradley, where it joins the *Trent and Merſey* canal, the latter company for the ſum of 500l. over and above the actual expences, undertook to complete this length, by agreements of the 29th October 1783, which the act (of 23d of Geo. III. above) confirmed; this they accompliſhed, the half neareſt to Fradley in January 1787, which the *Coventry* company in Oct. 1787 purchaſed of them, agreeable to the 23d Geo. III. (which occaſions them now to have a detached length of canal); the other half, between Whittington-brook and Fazeley, was completed in October 1789, and on payment of the coſt thereof by this company, it was conveyed and made over to them, agreeable to the act above quoted. On the 12th of July, 1790, the aqueduct bridge at Salford being completed, as well as the line of canal, the ſame was opened, and the water communication between Birmingham and Hull or London, was thereby effected. The ſums of money to be raiſed for this canal, were not diſtinguiſhed in the acts from what was intended for the extenſion and improvement of the old *Birmingham* canal, the amount of each ſhare was 170l.; but the act 24th Geo. III. limiting the number of ſhares to 500, they ſeem now to be variable. The rates of tonnage are too complicate for us to attempt their particulars, and we muſt refer the readers to *J. Cary's Inland Navigation*, pages 40 to 44, and pages 75 and 77. By the *Warwick and Birmingham* act (33d Geo. III.) certain duties are ſecured to this on goods paſſing from or to that canal, which may be ſeen in *Cary*, page 44. It is provided that the tonnage per mile on coals, is to be the ſame on this and the *Coventry* and *Oxford* canals.

*Biſhopſtortford and Cambridge.* In the year 1785 Mr. *John Phillips*, in a quarto treatiſe, recommended a line of canal from the *Stort* river, at Biſhopſtortford, to the *Cam*, at Cambridge, either by way of Littlebury and the Granta river, or near to Royſton by the upper part of the Cam; which might be done, he ſays, for little more than 20,000 l. but no levels, or other eſſential particulars are given; nor do we hear of any ſuch, when Mr. *R. Dodd* again revived this idea in 1803, and wiſhed to make this line part of his *North London* canal.

*Biſhopſtortford to Wilton.* In 1789 Mr. *John Rennie* was employed by ſeveral gentlemen of Eſſex to ſurvey and report on a line of canal from Hiſs, near Wilton, on the Brandon or Little *Ouſe* river, at the edge of the fens in Suffolk, to the *Stort* river at Biſhopſtortford; the diſtance from the little *Ouſe* to Ugley, the beginning of a propoſed tunnel (of ¾ of a mile) near Eſſingham, 45¼ miles, with a riſe of 251¼ feet; thence to Fuller's-end, near Eſſingham, 2⅗ miles, and level; and thence to the *Stort* at Biſhopſtortford, 4½ miles with 80 feet fall; a cut was propoſed to Burwell on a branch of the *Cam* river, and it was to croſs the *Lark* river. Several large reſervoirs were deſigned, and three tunnels, two of them being neceſſary to reach the town of Saffron-Walden, and to miſs Audley park. The eſtimate was 175,000 l. and a bill was brought into parliament, in 1790, for the ſame, but it there met a fatal oppoſition.

BLACKWATER NAVIGATION (*Ireland*). This river falls into Loch Neagh, and for extending a navigation therefrom to the Dungannon and Tyrone collieries, the Iriſh parliament, between 1753 and 1770, granted various ſums of the public money, amounting to 11,000 l.; a canal with 8 locks, terminating in a baſon, was conſtructed before Mr. *Davis Dukart* the engineer was employed thereon; who, finding the three miles with 200 feet riſe, which remained to do to reach the Tyrone collieries, to be too great for a canal with locks, he conſtructed, about 1776, four water-levels, with three inclined-planes, of 70, 60, and 50 feet riſe, to connect them, on which ſmall boats were made to aſcend and deſcend, as we have already mentioned, theſe being the firſt *inclined-planes* for boats brought into uſe in the United Kingdoms; it appears, however, that theſe were ſoon laid aſide in this place, and a *rail way* was ſubſtituted. This navigation was intended to connect with the *Newry* canal.

BLYTH RIVER. This river, between Northumberland and a detached part of the county of Durham, appears to be navigable but a ſmall diſtance above Blyth harbour; but we underſtand it has ſeveral conſiderable *rail-ways* connecting with it, for bringing down the produce of the collieries to the ſhipping.

BOYNE RIVER (*Ireland*). This is one of the rivers on the eaſt coaſt of Ireland, for which the parliament, between 1768 and 1771, granted 9,507 l. for improving its navigation. At Edenderry it was propoſed to be joined by a cut from the *Grand Canal*.

BRADFORD CANAL. Acts 11 and 42 Geo. III. The general direction of this ſhort navigation is ſouth nearly, and 3 miles in length, in the Weſt Riding of Yorkſhire. It is not conſiderably elevated: its objects are the export of coals, iron, and ſtone, the produce of the neighbourhood of Bradford, and the ſupply of Bradford town, which is the 95th in the ſeries, with 6,393 inhabitants. It commences in the *Leeds and Liverpool* canal at Winhill, in Idle pariſh, and terminates at Bradford, where *rail ways* of conſiderable extent connect with it, one of them goes to the collieries and iron-works on Wibſey Slack; and the deſcent is ſo ſteep that the waggons run down without horſes, having their velocity regulated by a man who rides behind and uſes the convoy or brake upon the wheels, as occaſion requires. From the *Leeds and Liverpool* canal to Bradford is a riſe of 81 feet by 8 locks; the width of the canal at top is 24 to 30 feet, and its depth is 5 feet; the locks are of the ſame width and length as thoſe of the *Leeds and Liverpool* canal. The company were empowered to raiſe 6000 l. in 100 l. ſhares. Boats paſſing the whole or any part of the diſtance on this canal are to pay 6 d. per ton for clay, bricks, ſtone, coals, lime, dung, and manure; and 9d. for every ton of iron, timber, and all other goods. This canal was finiſhed in 1774. The laſt act was found neceſſary, in order to make good the title to ſome lands which had been long before purchaſed for the works.

BRECKNOCK AND ABERGAVENNY CANAL. Acts 33 and 44 of Geo. III. The general direction of this canal is about N.W. 33 miles in length, in the counties of Monmouth and Brecknock in South Wales; it begins a few miles from the coaſt, and ſoon after comes near and follows the courſe of the Uſke river, no part of it being very greatly elevated. Its objects are the exportation of coals, iron, and other mineral products of the country round Abergavenny, by means of the *Monmouthſhire* canal, and the ſupply of Pontypool, Abergavenny, Crickhowel, and Brecon towns, that are near its courſe. It commences in the *Monmouthſhire* canal, 1 mile from Pontypool, and terminates at the town of Brecon; it has ſeveral *rail-way* branches: viz. to Abergavenny 1 mile; to Wain-Dew collieries and iron-works 4¾ miles (near 2½ miles of this laſt being double on each ſide of the brook); and, to Llangroiney 1¼ mile. From the *Monmouthſhire* canal, the firſt 14½ miles are level, to 3 miles above the Abergavenny branch, thence to Brecon is 18½ miles, with a riſe of 68 feet. Near its commencement it croſſes the little river Avon, on an aqueduct, and ſhortly after paſſes a tunnel of 220 yards in length. The engineer is Mr. *T. Dadford* jun. The Wain-Dew rail-ways, and the canal above them, up to Brecon, appeared to be finiſhed in June 1802, and by this time we expect the whole is completed, or nearly ſo. The company were at firſt authorized to raiſe 150,000 l. and a further ſum by their ſecond act, ſhares 100 l. each. The rates of tonnage are to be the ſame as thoſe on the *Monmouthſhire* canal, which ſee in *J. Phillips's Hiſtory*, 4to. *App.* p. 18. Horſes, mules, and aſſes are to pay 1 d. and cows, or neat cattle ½ d. each at certain toll-gates on the rail-ways. The *Monmouthſhire* canal, on account of the great benefit this will confer on it in tonnage, agreed to pay this company in March 1794, the ſum of 3000 l. In May laſt (1805) it was propoſed to extend a rail-way branch from this canal to connect with the river *Wye*.

*Bredon Rail-way.* About the year 1793 it was in contemplation to make a rail-way and canal from the famous lime-works at Bredon to the *Trent* river, oppoſite to Weſton Cliff; and in conſequence, a clauſe is inſerted in the *Derby* canal act, of 33 Geo. III. binding them to make a cut from the *Trent* at Weſton Cliff to the *Trent and Merſey* canal, which runs parallel with the *Trent*, whenever this ſcheme ſhall be adopted, in order to give this lime a readier courſe into Derbyſhire.

BRIDGEWATER'S CANAL. Acts 32 and 33 of Geo. II., the 2d, 6th, (*Trent and Merſey act*) and 35th of Geo. III. The general direction of the principal line of this canal is nearly N.E. (and not a great way from its eaſtern end, a main branch goes off in a N.W. direction nearly); the length is 40 miles, in the counties of Cheſter and Lancaſter. It begins in the tide-way; above which the whole of it is elevated 82 feet at low-water, except about 600 yards, which the locks occupy to gain this aſcent. The great objects which induced the late excellent and patriotic *duke of Bridgewater* to undertake and to expend a princely fortune on the completion of this canal were, the ſupply of the town of Mancheſter with coals from his eſtates near Worſley; the cheaper and more expeditious conveyance of goods, between Mancheſter and Liverpool, than the *Merſey and Irwell* river navigation then furniſhed; and between both of theſe places and the interior and moſt remote parts of the country, by means of the *Trent and Merſey* (which it joins at Preſton Brook,) and its connecting canals. Other and more direct communications have ſince been made between it and the interior and eaſtern parts of the kingdom, by means of the *Rochdale* canal and thoſe connecting therewith. Mancheſter is the 2d place in Great Britain for population, having 84,020 inhabitants, Liverpool the 4th with 77,653 inhabitants, and Warrington the 45th with 10,567 inhabitants, theſe towns being near this canal. The commencement of this canal is in the eſtuary of the *Merſey* river at Runcorn-gap, and one of its terminations in the *Rochdale* canal at Caſtle Field in the town of Mancheſter, the other (or Worſley branch) is at Pennington near the town of Leigh, the junction of theſe branches being at Longford bridge; near Mancheſter there is a communication with the *Merſey and Irwell* navigation, and *Mancheſter Bolton and Bury* canal, by means of Medlock brook. Under the town of Mancheſter are arched branches of the canal of conſiderable length, from one of which coals are hoiſted up by a coal-gin, through a ſhaft out of the boats below, into a large coal-yard or ſtore-houſe in the main ſtreet, at which place the duke and his ſucceſſors, are by the firſt act bound to ſupply the inhabitants of Mancheſter at all times with coals at only 4d. per cwt. of 140lb.; a circumſtance which muſt have had a great effect on the growing population of this immenſe town within the laſt 40 years. At Worſley is a ſhort cut to Worſley mills, and another to the entrance baſon of the famous under-ground works or tunnels, of 18 miles or more in length in different branches and levels, for the navigation of coal-boats; ſome of which are as much as 60 yards below the canal, and others 35½ yards above the canal; theſe laſt, to which the boats aſcend by means of an *inclined-plane*, that we have already deſcribed, extend to the veins of coal that are working at a great depth under Walkden Moor. Moſt of theſe tunnels are hewn out of the ſolid rock; from the lower one, the coals in boxes are hoiſted up out of the boats, as they are in Mancheſter town mentioned above, and the whole of the lower works are prevented from filling with water, by large pumps worked by the hydraulic machine, which we have already mentioned in this article, and the water is thereby always kept at the proper height for navigation on the lower canal. Near Worſley, a branch of about 1½ mile in length, proceeds on to Chat-Moſs and there ends, acroſs which celebrated moraſs, it was by the firſt act intended to proceed, to the *Merſey and Irwell* navigation at Hollin Ferry near Glazebrook; but, like the cut propoſed by the ſide of the Merſey to Stockport (7½ miles with a riſe of 60 feet) was never executed, and the neceſſity for them is now in a great meaſure done away, by other plans which have been carried into effect. The riſe of 82 feet in the firſt 600 yards from the *Merſey*, by 10 locks, is the only deviation from one level on this canal (except in the Worſley coal-mines above mentioned); and this length of level-water is further increaſed; by 18 miles on the *Trent and Merſey* canal which connects therewith, making in all 70 miles of level. The width of the canal at top is 52 feet on the average, and depth 5 feet; the boats that navigate between Worſley mines and Mancheſter are only 4½ feet wide, the others are 50 ton boats or upwards; there are alſo numerous boats for paſſengers; large warehouſes have been built for goods, at the Caſtle Field in Mancheſter adjoining the canal.

Beſides the tunnels under Mancheſter and at Worſley mines, we have been through a ſhort one in paſſing a gentleman's houſe and a church, we think at Groppenhall. On this canal are three principal aqueduct bridges over the *Irwell* at Barton, where it is navigable, and over the Merſey and Bollin rivers, beſides ſeveral ſmaller ones, and many road-aqueducts. There are alſo ſeveral large embankments, one over Stretford meadows, is 900 yards long, 17 feet high, and 112 feet wide at the baſe; that at Barton bridge is 200 yards long, and 40 feet high; at Bollington is alſo a ſtupendous embankment. The principal feeders for this canal are Worſley brook, and the mine-water there collected, the Medlock brook at Mancheſter, and the lockage of the *Trent and Merſey* canal; and water, which never was ſcarce in this canal, muſt now abound, ſince the increaſe of ſupply by the lockage of the *Rochdale* canal.

Mr. *James Brindley*, the engineer, owed much of his well earned fame to the happy contrivance and complete execution which he diſplayed in every part of this great concern; ſince the deceaſe of Mr. Brindley, Mr. *Gilbert* and Mr. *Benjamin Sothern* his Grace's agents, have done themſelves great credit, by the maſterly manner in which they have conducted the canal concerns of their noble employer, and improved and extended his works, as Mr. *Thomas Bury* has alſo in the mining department, ſo intimately connected therewith. The tunnelling at Worſley, and the canal between that and Mancheſter, were begun immediately on the paſſing of the firſt act; on the 17th of July, 1761, the Barton aqueduct was completed, and coals were ſoon after conveyed thereby to Mancheſter. On the 31ſt of December, 1772, the 10 locks at Runcorn were opened; in Auguſt, 1774, two packet-boats began to proceed regularly part of the way between Mancheſter and Liverpool, and on the 21ſt of March, 1776, the whole of the works which were then intended were finiſhed; the extenſion to Leigh has been made ſince 1795. The illuſtrious *duke of Bridgewater*, juſtly ſtiled *the father of Britiſh Inland Navigation*, died greatly lamented in March 1803, and left this immenſe concern, (which coſt at firſt 220,000l. it was ſaid, and probably in the whole twice that ſum, as the tunnelling at Worſley alone has been eſtimated at 168,960l.), to *earl Gower*, the preſent proprietor, whoſe ſecond ſon is to inherit it; the net profits are ſaid now to be from 50 to 80,000l. annually. The tonnage has not been increaſed ſince the firſt act, although the length of the canal has been increaſed to nearly four times what was at that time intended; boats may navigate the whole courſe or any part on paying 2s. 6d. per ton. Veſſels paſſing out of the *Trent and Merſey* at Preſton-Brook and into the *Merſey* at Runcorn, or the reverſe, pay 1d. per ton per mile for that diſtance; and all veſſels paſſing to or from the *Rochdale* canal to this canal at Mancheſter are to pay, for paving ſtones 4d. per ton, and for all other articles 14d. per ton. It is provided, that flour ſhall not pay any tonnage on this canal, if the wheat whereof it was made had already paid. Irrigation, or watering of meadows, is practiſed in a very judicious and profitable manner, by water let out of this canal at Worſley and other places. The price of land-carriage for goods between Mancheſter and Liverpool was, on the paſſing of the Duke's third act, 40s. per ton, and by the navigation on the *Merſey and Irwell* 12s. per ton, but his Grace limited his price to 6s. per ton: yet, ſuch has been the increaſing trade of theſe two places, that it was in 1794 ſeriouſly maintained, and made the ground of another propoſed navigable communication, by a junction of the *Mancheſter Bolton and Bury*, and the *Leeds and Liverpool* canals, that both the Duke's canal and the river navigation were inadequate to carry the trade between Mancheſter and Liverpool, and that the moſt frequent and ruinous delays were experienced by the merchants. In 1802, we find the idea again revived of a cut from the *Leeds and Liverpool* canal to the Leigh branch of this canal. About 1772, the *Liverpool and Runcorn* was propoſed as an extenſion of this canal from Runcorn; in 1799, the *Mancheſter Bolton and Bury*, was propoſed to be joined directly with this canal, by means of aqueducts over the Irwell and Medlock at Mancheſter.

*Briſtol and Glouceſter*. In the year 1797, we were told, that ſurveys were making of the line for a propoſed canal from the Bath *Avon* at Briſtol to the *Severn* at Glouceſter, and alſo, of a continuation of the ſame acroſs the Stratford *Avon* to the *Severn* at Worceſter.

*Briſtol and Taunton*. Several years ago, a canal was propoſed, we are told, from the *Avon* river at Briſtol to the town of Taunton, with cuts to Nailſea collieries, to the *Axe* river at Brean, and to the town of Langport, but we are not further acquainted with its objects or particulars.

BROTHIC RIVER. This is a ſmall river on the coaſt of Angers county in Scotland, and navigable, we believe, but a ſmall diſtance up from the harbour of Aberbrothick at its mouth, which harbour is of great antiquity, and appears to have had piers and works erected for its improvement and ſecurity, ſo long back as the year 1194; the ſpring tides here riſe 15 feet.

*Bude and Hatherleigh* canal. In 1793, the *earl of Stanhope* propoſed a line of water-levels and rail-ways, between the ſea in Bude Haven, on the Briſtol-Channel part of the Corniſh coaſt, and the neighbourhood of Hatherleigh in Devonſhire, paſſing the town of Holdſworthy, for carrying up ſea-ſand, (which in this bay conſiſts of a congeries of broken ſhells), as a manure, and exporting of farming produce; the riſe on this line was upwards of 500 feet, up which his lordſhip propoſed, that his 2 ton boats ſhould be conveyed at proper intervals on inclined-planes, whoſe peculiarities have been already mentioned in this article. In April laſt (1805), we find a ſcheme on foot, for improving the harbour of Bude and building a pier for the protection of ſhips.

*Bude and Launceſton*, or the Tamar canal. This is one of the few inſtances, in which an act (14th of Geo. III.) was obtained, without any part of the ſcheme having been carried into effect. Mr. *Edmund Leach* the projector of this, in his Treatiſe on Inland Navigation, propoſed, that it ſhould proceed from the tide-way in Bude Haven, Cornwall, on the Briſtol Channel, and proceed near to Launceſton, and into the tide-way in the river *Tamar* near Calſtock, in the S.E. part of Cornwall. There was a proviſion, that the powers of the act were to ceaſe in 10 years, if the canal was not proceeded with; it was propoſed, to purchaſe only 39 feet wide of land, and not to be allowed to cut more than 39 inches deep into the earth on the lower ſide, in any part, except for docks, &c.; the canal to be 21 feet wide at top and 12 at bottom, with a towing-path on each ſide of it, 10 ton boats to be uſed; the direct diſtance of the two extreme points is only 28 miles, but owing to the extremely ſerpentine courſe of the level which was to be followed, its propoſed length was 81 miles, and was eſtimated to coſt 1000l. per mile. Locks were not to be uſed, but *inclined-planes* for boats of Mr. Leach's contrivance, of which we have already given an account in this article. From the ſea at Bude, was to be a plane of 54 feet riſe, thence a level of 6½ miles, then a plane of 120 feet riſe, then 4 miles of level, and a third plane of 66 feet riſe to the ſummit-level, which extended 34 miles to Launceſton town, and 34 miles beyond; then, a plane with a deſcent of 120 feet, then 2½ miles of level, and a fifth plane, at Kelly Rock, of 120 feet fall to the *Tamar* navigation. A cut or feeder of 3 miles was propoſed, from the Tamar is Lanells to St. Tankins on the Pack-ſaddle (being a low point on the ſouth-weſtern branch of the grand-ridge). Mr. Leach, however, tells us, that theſe levels are not to be entirely depended on, and mentions 258 feet as the elevation of the Pack ſaddle. The principal objects of this canal were the carrying of ſalt and ſhelly ſand from the coaſt into the interior of the country as manure (an object ſince in part accompliſhed by the *Tamar manure*, and the *Stover* canals). In 1785, Mr. *Leach* wiſhed to revive this project, and to ſhorten the courſe to 40¾ miles, by cutting down the ſummit 18 feet, and making a tunnel of 100 yards; and to form another communication with the ſea at Weedmouth-bay, where the ſame broken ſhells abound; the coſt was now eſtimated at 53,100l.

BURROWSTOWNESS CANAL. The act of the 8th of Geo. III. (for the *Forth and Clyde* canal) eſtabliſhed a ſet of proprietors for this canal; its direction being nearly weſt for about ſeven miles in the counties of Linlithgow and Stirling, in Scotland; from the tide-way in the harbour of Borrowſtowneſs, on the Firth of *Forth*, to the *Forth and Clyde* canal, near its eaſtern termination at Grangemouth. Its objects are ſtated to be, the avoiding part of a dangerous and difficult navigation on the *Forth*, and for improving the lands of Kinniel and Beercrofts, through which it paſſes. Burrowſtowneſs, Linlithgow and Falkirk are conſiderable towns near this line. The depth to be ſeven feet, and width and ſize of the locks at the entrance proportionable thereto, the canal being level. The company are authoriſed to raiſe 8,000l. the ſhares to be 50l. each. The tonnage of lime, lime-ſtone, and iron-ſtone ½d. per ton per mile, all other goods and articles (except road-materials and manures) 1½d. per ton per mile.

BURRY RIVER. This river, or eſtuary, connecting with the Briſtol Channel, is between the counties of Caermarthen and Glamorgan, in South Wales, and is navigable a diſtance of ten or eleven miles to Lwghor or Llougher, in nearly an eaſt direction; at the flats in Llanelly it is joined by the *Caermarthenſhire* rail-way, and another rail-way has lately been laid from this river to the Penclawdd copper-works: in 1801, the *Llandorry and Llanelly* canal was propoſed to join at the Spitty in Llanelly; and, in October 1805, a wet dock was propoſed to be made on the eaſt ſide of the Llanelly pier, to communicate with the *Caermarthenſhire* rail-way.

*Caerdyke*. This is an artificial channel or ditch, as ancient as the time of the Romans in this country, from the *Nen* river, a little below Peterborough, to the *Witham* river, three miles below Lincoln, of near 40 miles in length; it appears to have been very deep, though now almoſt grown up; and it is rather doubtful whether it ever was intended or uſed for the purpoſes of navigation.

CAERMARTHENSHIRE RAIL-WAY. Act 42 Geo. III.— The general direction of this line of rail-way is nearly north for 14 or 15 miles in Caermarthenſhire; it commences on the coaſt, and is not very greatly elevated in any part; its general objects are the export of coals, iron, lead, &c. from the country through which it paſſes. Llandillo Vawr is the only conſiderable town near its courſe. It commences in the *Burry* river, at the new baſon for ſhips, at the flats near Llanelly, and terminates at Caſtel y-Garry lime-works in Llanſihangel Aber-bythick. In the deep cuttings for this rail-way near Munydd Mawr ſeveral unknown veins of good ſtone-coal were diſcovered, and ſome of lead ore; in November 1804, the embankment near this place, conſiſting of more than 40,000 cubic yards of earth was completed, with the rail-way upon it. In October 1805, it was propoſed to make a wet-dock for ſhips at the commencement of this line, on the eaſt ſide of Llanelly pier; in 1801, the *Llandovery and Llanelly* canal was propoſed to paſs through nearly this line of country.

Caistor Canal. Act 33 Geo. III.—The direction of this line is eaſt 9 miles in the county of Lincoln; it is but little elevated above the ſea. Its objects ſeem the importation of fuel and other articles, for the ſupply of Caiſtor town, and the export of farming produce: it commences in the *Ancholme* navigation, at South Kelſey, and terminates at the town of Caiſtor. The company were empowered to raiſe 25,000l., ſhares 100l. The rates of tonnage are from 2d. to 8d. per ton per mile on different goods, with other rates for corn, &c. See *Phillips*'s 4to. *Hiſtory*, p. 47. All ſtores for the uſe of government, or materials for roads, to paſs free at all times, and manures for the adjoining lands, when the waters run over the lock-weirs. In 1801, there was a propoſal for extending this canal from Caiſtor, along the foot of the Woulds, ſoutherly, to Hambleton Hill, in Tealby, near Market-Raiſin, the expence of which was eſtimated at 6,500l.

Calder and Hebble Navigation. Act Geo. III.—The general direction of this navigation is nearly weſt, about 23 miles in length, in the weſt riding of Yorkſhire; it has a conſiderable elevation above the ſea at its weſt end: the general objects are the communication between Liverpool, Mancheſter, and Hull, by means of the *Rochdale* and *Hudderſfield* canals, and *Ayre* and *Calder* rivers, the import and export of goods from Halifax, and the export of paving-ſtone (now ſo much uſed in London, called Yorkſhire paving) from the famous quarries at Ealand-Edge and Cromwell-Bottom, and lime from Houghton, Brotherton, and Fairburn: at Cooper's Bridge it is joined by Sir John *Ramſden*'s canal (leading to the *Hudderſfield* canal), and at Dewſbury by the *Dewſbury and Birſtal* rail-way. Halifax is the 58th Britiſh town, with a population of 8,886 perſons; Wakefield the 64th, with 8,131 inhabitants; and Hudderſfield the 81ſt, with 7,268 perſons. This navigation begins in the *Ayre and Calder* navigation on the latter river, at Wakefield, and terminates in the *Rochdale* canal, at Sowerby-Bridge. There is a rail-way branch of about half a mile to Bradley collieries; it has a cut of about half a mile in length by the ſide of the Hebble river, to Salter-Hebble; and proviſion is made (in 33 Geo. III. for *Barnſley*) for a cut to Bargh-mill, on a branch of *Barnſley* canal; there are ſeveral locks; one of them near Salter-Hebble, of 10 or 12 feet riſe, was in 1783 removed, and two new ones, of half that height, with a baſon between them, were ſubſtituted by Mr. *William Jeſſop*; ſome of the locks here erected in 1761, by Mr. *Smeaton*, have ſingle gates at their heads. At Salter-Hebble are a baſon and large warehouſes, and others at Sowerby Bridge, for the accommodation of the town of Halifax; near Ealand is a large weir acroſs the *Calder* river. This navigation was planned or ſuperintended by Mr. *James Brindley*, and afterwards by Mr. *John Smeaton*. About 1765, the navigation was brought up to Ealand quarries, and about 1776, to Salter-Hebble, and to Sowerby-Bridge warehouſes. The ſtone and white ſlate from Ealand-Edge are carried in carts and four-wheeled carriages, to be put on board of the keels at Bridgehouſe wharf, on account of the great height of the quarries above the *Calder*; the Cromwell bottom-ſtone is put on board at a wharf there. From the quarries of *Thomas Thornhill*, Eſq. at Lillon's Wood, near Ealand, a long and wide inclined plane, of about 45° of elevation, was, about the year 1774, made from the *Calder* river, and paved with large flat ſtones, on which a ſledge deſcended loaded with ſtone, and by means of a rope paſſing over a wheel and axle, drew another empty ſledge up the plane; this continued in uſe for ſome years; but this quarry was diſuſed before the year 1783. In 1762, a violent flood happened on the *Calder* river, which deſtroyed many of the works thereon; theſe Mr. *Smeaton* repaired, and in 1774 another happened, ſo deſtructive that the navigation was for near a year ſuſpended, before they were repaired; the fall of this river is no leſs than 8 feet per mile for more than 20 miles together. By the act 34 Geo. III. for *Hudderſfield* canal, this navigation was guaranteed againſt a diminution of its tolls, by any other communication to the eaſtward opened therewith. In 1794, the *Mancheſter Bolton and Bury* canal was propoſed to be extended to join this at Sowerby-Bridge. In 1802, the *Wibſey and Dewſbury* rail-way was propoſed to join at Raven's Bridge, and notices have in the preſent autumn (1805) been given for the *Wakefield and Hullet* rail-way, intended to join this navigation at Bottom-Boat, near Wakefield; a ſide-cut is now making near Bridge-houſe, for avoiding the mill-dams, and improving this navigation.

Cam River. The general direction of this navigation is about ſouth-weſt, for 14 or 15 miles in the county of Cambridge; it is but little elevated above the level of the ſea; its principal object is the ſupply of the town of Cambridge, which is the 51ſt in the order of our population, with 10,087 inhabitants: Ely alſo, near this navigation, is a conſiderable place. It commences in the great *Ouſe* river, at Harrimere, and terminates in the town of Cambridge. It has a cut or reach of 3 miles to Reche, and another of $3\frac{1}{2}$ miles to Burwell, at which laſt place the *Biſhopſtortford and Wilton* canal was, in 1789, propoſed to join. The *Cam* river is embanked above the adjoining fens through all its lower parts, is without locks in ſome parts, and has ſluices for making fluſhes of water, to enable boats to paſs the ſhallows and hards.

Camel River. The general direction of this navigation is about ſouth-eaſt for near 8 miles, in the county of Cornwall; it is within the flow of the tide, and is chiefly uſed in the import of coals and export of agricultural produce: it connects at Guinea-Port, near Wadebridge, with the *Polbrock* canal. Padſtow, on its banks, is a conſiderable town; it commences in the Iriſh channel, at Stepper Point, and terminates at Wadebridge.

*Canterbury and Nicholas-Bay.* In the year 1802, a canal was propoſed, and again in 1804, and ſurveys taken, for a canal on a level, capable of carrying ſea-built veſſels, between the ſea at St. Nicholas Bay, near Margate, to the city of Canterbury, about 10 or 11 miles in a ſouth-weſt direction, there to connect with the *Stour* river, and with a canal then propoſed, called the *Medway and Rother* canal. Canterbury has 9000 inhabitants, and is the 57th place in the order.

Cardiff and Merthyr-Tydvil Rail-way. Act about 35 Geo. III.—This line is nearly in a north-weſt direction, for $26\frac{3}{4}$ miles, in the county of Glamorgan, in South Wales. The general object of this rail-way is the export of iron from the great works at Merthyr Tydvil, Dowlais, &c. Cardiff, Caerphilly, and Merthyr are conſiderable towns on or near this line, which commences at the floating-dock, in the *Severn* at Lower Layer, the termination of the *Glamorganſhire* canal, by the ſide of which, very nearly, it proceeds to Merthyr Tydvil, and thence to the lime-works at Panton, in Merthyr pariſh; at Quaker's yard a branch of

9½ miles goes off to Carno mill, in Bedwellty; *Homfray, Hill* and Co. are the proprietors of this rail-way or tram-road, and it was, we believe, conſtructed under the firſt act of parliament ever paſſed for this kind of roads; the width of land allowed to be purchaſed was 7 yards. On the 21ſt Feb. 1804, a trial was made of one of Trevethic's high-preſſure ſteam-engines for drawing trams on this tram-road, as before mentioned, and 10 tons of iron and 70 perſons were drawn for 9 miles by the power of ſteam, without the uſe of condenſing-water. At Merthyr there is a curious and ſtupendous water-wheel, of 50 feet diameter, made of caſt-iron.

CARON RIVER. The direction of this river is weſt, in the county of Stirling, in Scotland, and for 3 miles it is navigable, from the *Forth* river to Caron ſhore, for veſſels drawing 7 or 8 feet water at neap-tides; at Caron ſhore there is a cut from the *Forth and Clyde* canal; and near Caron ſhore are the famous Caron iron-works.

CART RIVER. The direction of this navigation is nearly ſouth, for about 3 miles in Renfrewſhire, in Scotland; its objects being the ſupply, and the exports and imports of the great manufacturing town of Paiſley, which is the 15th in the order of Britiſh towns, and contains 31,179 perſons. Renfrew is alſo a conſiderable town near the ſame: this navigation commences in the *Clyde* river, near Inchinnan, and terminates at the town of Paiſley, at which place it was propoſed, in 1803, to be joined by the *Glaſgow and Saltcoats* canal.

CHELMER AND BLACKWATER NAVIGATION. Acts 6 and 33 Geo. III.—The general direction of this navigation is nearly weſt for 13⅝ miles in the county of Eſſex; its general objects are the ſupply of Chelmsford and its neighbourhood with coals, deals, &c. and the export of farm produce. It commences in the Tide-way, at Collier's-Reach, in the eſtuary of Blackwater river, and proceeds by the courſe of the Chelmer river to the baſon at Chelmsford town, with a cut near ¼ of a mile to Malden. Chelmsford and Malden are conſiderable towns. From low-water in the baſon at Collier's reach to Heybridge-mill, on Blackwater river, 1⅝ mile, is a riſe of 12 feet 8½ inches, thence to Beely or Baily-mill, on Chelmer river, 1⅛ mile, is a riſe of 7 feet 3½ inches; thence to the baſon at Chelmsford is 10⅞ miles, with a riſe of 59 feet 5 inches: the branch has a riſe 6 feet 8½ inches into the baſon at Malden. Mr. *John Smeaton* ſurveyed this line in 1762, and recommended 13 miles of new canal, and eſtimated the ſame at near 16,700 l.; Mr. *John Rennie* was afterwards employed. The baſon at Collier's reach was opened for ſhips in February 1796; the company were authorized to raiſe 60,000 l. the amount of ſhares 100 l. each; in 1802 theſe were ſo depreciated, that they were ſaid not to be worth 5 l. each. The ſpring-tides flow 5 feet at Baily-mill-tail, and 8 feet at Malden bridge; the neap tides do not raiſe the water above one foot at the laſt place.

*Cheltenham and Tewkſbury.* In 1801, notices were given for a propoſed canal from the *Severn* river, near the junction of the *Avon* therewith, at the town of Tewkſbury, to the town of Cheltenham, through the pariſhes of Tewkſbury, Tredington, Elmſtone-Hardwick, Uckington, Swindon, and Cheltenham, a courſe nearly ſouth-eaſt for about 8 miles, in the county of Glouceſter. Tewkſbury and Cheltenham are conſiderable places.

CHESTER CANAL. Acts 11 and 17 Geo. III.—The general direction of this canal is about ſouth-eaſt for 18 miles, in the county of Cheſter; it is not greatly elevated above the level of the ſea; its principal objects are the export of farming produce, and the import of coals and lime for Nantwich town, and the ſurrounding country; it forms a double communication between two points in the line of the *Elleſmere* canal, at Cheſter and at Franckton common. Cheſter is the 25th Britiſh town, with a population of 15,052 perſons. Nantwich is alſo a conſiderable town. This canal commences in the tide-way in the *Dee* river, in the town of Cheſter, near to where the *Elleſmere* canal croſſes the ſame, and terminates at the town of Nantwich; at Stoke, in the pariſh of Acton, it is joined by the Whitechurch branch of the *Elleſmere* canal; from Cheſter to Barbridge, near Tiverton, the diſtance is 14¾ miles, with a riſe of 170 feet 10 inches, and thence to Nantwich it is 3¼ miles, and level. The canal paſſes Chriſtleton, Waverton, Hargrave, Huxley, Braſſey-green, Beerton-caſtle, Tiverton, Hurleſton, Acton, and Nantwich; there is an aqueduct at Huxley-mill. Mr. *James Brindley*, and other engineers, were employed in 1767, 1769, and 1770; in 1769 an unſucceſsful attempt was made to obtain an act for it; it was begun in 1772, and was completed from the *Dee* to Huxley-mill 16th June 1775, and ſhortly after to Nantwich; a branch was provided for in the act, from Barbridge, 8⅝ miles long, with a fall of 40 feet, to Middlewich, near to the *Trent and Merſey* canal, but not into it. Although this branch, intended for bringing ſalt to Cheſter, was not executed, the expences amounted to 80,000 l. and the ſhares became perhaps the moſt depreciated of any concern in the kingdom, being ſold at one time, as we are informed, for one per cent. of their original value. In 1793, a junction was propoſed near Nantwich, with a branch of the intended *Sandbach* canal; in 1793, a rival ſcheme to the *Elleſmere*, called the Eaſtern Grand Trunk, was propoſed to join at Crows-neſt; and in June 1796 the *Commercial* canal was propoſed to join at the ſame place, in order to form by means of the *Aſhby-de-la-Zouch* canal, and others, a communication for 40 ton boats, between Liverpool, Cheſter, Hull, London, &c.

CHESTERFIELD CANAL. Act 10 Geo. III.—The general direction of this canal is nearly ſouth-weſt, by a crooked courſe 46 miles in length, in the counties of Nottingham, York, and Derby; the weſtern end is conſiderably elevated; its principal objects are the export of coals from near Cheſterfield, and lead from the Derbyſhire mines, and the import of lime, corn, timber, &c. Cheſterfield, Workſop, and Retford are conſiderable towns upon this line, which commences in the *Trent* river, near its junction with the *Idle* river, at Stockwith, and terminates at Cheſterfield town; from the *Trent* to Workſop the diſtance is 24 miles, with a riſe of 250 feet; thence to Norwood it is 9 miles, with a riſe of 85 feet; and thence to Cheſterfield it is 13 miles, with a fall of 45 feet: the number of locks is 65; the lower part of the canal, from the *Trent* to Retford, is for large boats of 50 or 60 tons burthen; above this the width is 26 to 28 feet, and depth of water from 4 to 5 feet; the boats here uſed being 70 feet long and 7 wide, and carrying 20 to 22 tons each. In 1794 ſuch boats as theſe coſt, when new, 90 to 100 l. each. The boat-owners here uſually pay their bargemen by the ton of goods which they convey ſtated diſtances, inſtead of weekly wages. At Norwood is a tunnel through Hartſhill of 2850 yards in length, being 12 feet high and 9¼ wide withinſide the arch, and 36 feet below the ſurface of the hill; this tunnel was begun in November 1771, and finiſhed the 9th May 1775; at Drake's-hole is another tunnel of 153 yards in length. Mr. *James Brindley* projected this canal, and directed its execution until his death in September 1772, when his brother-in-law, Mr. *Henſhall*, ſucceeded, and completed the whole in 1776. The tonnage is 1½d. per ton per mile, and in calculating the ſame ⅙th of a mile is taken into account, and ¼th of a ton. It appears that the canal coſt 160,000 l. and the ſhares were at firſt much depreciated, and ſold for a long time below par; in September laſt (1805) the profits amounted to 6l. per cent. annually. In Mr. *Brindley*'s time, a junction was intended at Cheſterfield with the propoſed *Cheſterfield and Swarkſtone* canal; and in 1802, an extenſion of this canal was propoſed of 5 or 6 miles in length, nearly ſouth to Aſhover.

*Cheſterfield and Swarkſtone.* The late Mr. *Brindley*, about the year 1771, propoſed a canal from the *Trent and Merſey* canal at Swarkſtone to the *Cheſterfield* canal at the latter place, the direct diſtance being about 25 miles nearly north, the line being through a country very rich in coals. Derby, the 43d town, with 10,832 inhabitants, was to be in the line of this canal, and the town of Belper is alſo near it.

Chicheſter Haven. This inlet of the ſea, on the coaſt of Hampſhire, is of conſiderable length, in different branches, navigable for ſhips, ſurrounding Thorney Iſle, and connecting with Langſtone and Portſmouth harbours. Havant and Chicheſter are conſiderable towns near it. In September 1805, notices were given for cutting a ſhort canal, to commence with a ſea-lock in deep water in this haven, and proceed to Upper Southgate field, in Chicheſter, there to terminate in a ſpacious baſon or dock.

Cleddy River. This river has nearly a north-eaſt courſe, in the county of Pembroke, in South Wales. It commences in the tide-way in *Milford Haven*, and terminates at Canniſter bridge, near Narberth, which is a conſiderable town; and Pembroke on another branch of the haven is alſo a conſiderable place.

Clyde River. Acts 34 Geo. II. and 9 and 11 of Geo. III.—This river or frith commences with a moſt noble and capacious eſtuary, in the northern or Iriſh channel, and extends nearly north, to Gonrook, when its direction changes towards the eaſt, and its width diminiſhes gradually to Glaſgow, where the navigation terminates. Glaſgow is the 5th town in Britain, in point of population, containing 77,385 inhabitants: Paiſley, in the vicinity of this river, is the 15th town, with 31,179 perſons; Greenock, the 20th, with 17,458 perſons; and Rothſay, (on the Iſle of Bute) the 118th, with 5,281 perſons: Ruther-Glen, Renfrew, Dumbarton, Port-Glaſgow, Irvine, and Ayr, are alſo conſiderable places on or near the banks of this river. At Glaſgow baſon a branch of the grand *Forth and Clyde* canal joins this, as alſo the *Monkland* canal, and *Edinburgh and Glaſgow* canal; near Inchinnan the *Cart* river joins, and at Dalmure Burnfoot; the weſtern termination of the *Forth and Clyde* canal is in this river; while the navigable lochs and ſounds which connect therewith below Dumbarton are both numerous and important; by means of lochs, Fine, and Gilp, there is a connection with the *Crinan* canal. In the year 1805 an act (45 Geo. III.) was obtained by the earl of *Eglinton* and others, for building new piers and improving *Ardroſſan* harbour, and building wet-docks, &c. near Saltcoats, on this river, and in this harbour, as well as at Glaſgow, the *Glaſgow and Saltcoats* canal was, in 1803, propoſed to connect therewith; at Rothſay, on the Iſle of Bute, piers have been built, and the harbour connecting with this river improved; *Greenock* harbour is alſo under great improvement, in conſequence of an act of 43 Geo. III. The trade on this river is very immenſe and various; it appears that Greenock alone employed 175,551 tons of ſhipping thereon in the year 1800.

Codbeck Brook. Act 7, Geo. III.—The direction of this navigation is nearly north for about ſix miles, in the north riding of Yorkſhire, commencing in the *Swale* river near Topcliff, and extending to the town of Thirſk, for whoſe accommodation it is intended.

Colne River. The general direction of this navigation is nearly N.W. for about 8 miles, in the county of Eſſex; its objects are the import of coals, deals, &c. and the export of farm produce, and of oyſters from the banks below Wivenhoe. Colcheſter is the 39th place in Britain, with a population of 11,520 perſons. It commences with an eſtuary at Merſey iſland, and terminates at the town of Colcheſter, to which place ſmall ſea-built veſſels can get up. Large ſhips navigate to Wivenhoe, where there is a dock-yard for building frigates and large trading ſhips.

St. Columb Canal. The general direction of this canal is nearly eaſt for ſeven or eight miles, in the county of Cornwall; although near the coaſt, it is conſiderably elevated. Its objects are the export of a particular ſpecies of ſtone found about St. Dennis, called China-ſtone, uſed in great quantities in Wedgewood's, and other potteries near the line of the *Trent and Merſey* canal, and the import of coals, and of a ſea-ſand conſiſting of broken ſhells for manure. This canal was propoſed to proceed acroſs the weſtern branch of the grand ridge to the ſouth coaſt; not one third of which length has, however, been carried into effect. St. Columb Major, St. Auſtel, and Grampound, are towns near the line. It commences at the ſea-ſhore of the Iriſh channel near St. Columb Minor, and terminates at preſent within about two miles of St. Columb Major; from thence it was to paſs St. Dennis, St. Stephen, St. Ewe, and arrive at the ſea again near Pentuan, not far from the famous Polgarth mines and engines. The part which was completed about the year 1775, commenced on the top of a very high cliff, and purſued the courſe above mentioned, without locks, we believe. The canal was a narrow one, and at its weſt end, the cliff was with great labour hewn down, into a ſteep inclined plane, that was covered with planks: the canal was conducted to the very top of this plane, and the boats which were rectangular ones, were brought, when loaded with ſtone, to the termination of the canal, where they were faſtened by a ſort of hinges; ſtrong ropes were then attached to the ſtern of the boat, and by means of a wheel and drum, worked by a horſe-gin or wem; the boat was hauled up an end, and the ſtones were thereby ſhot out, and rolled down the plane to the ſtrand below, from whence boats conveyed them on board the ſhips. The ſame wheel and drum was adopted for drawing boxes of coals or Shelly ſand up the plane, in order to their being loaded into the returning boats. Near to its eaſtern termination the canal was conveyed on an aqueduct bridge over a road. We have been favoured with theſe particulars by a Corniſh gentleman, ſince our account of inclined planes was written, or we ſhould have noticed this (the plane on *Parnel*'s canal and another on the *Calder and Hebble*) as early inſtances of the uſe of inclined planes for boxes of goods, &c. For ſeven or eight years this canal continued in uſe, but whether like the *Mawgan* canal, in its neighbourhood, it has ſince been diſuſed, we are not at the preſent moment able to learn.

*Commercial Canal.* In the year 1796, Mr. *Robert Whitworth* was employed to ſurvey this line, proceeding from the *Cheſter* canal at Nantwich to the *Aſhby de la-Zouch* canal near that town; it was propoſed to join Sir *Nigel Griſley's* canal and the *Newcaſtle under-line* canal, to croſs the *Trent and Merſey* canal near Burſlem, and proceeding by Uttoxeter, to croſs the *Trent and Merſey* canal again, and the *Trent* river at Burton. The objects of this propoſed canal were, the forming of a communication for larger boats (40 tons) than the *Trent and Merſey* is calculated for, except below Burton, and contributing towards the wiſhed-for paſſage of large boats between Liverpool, Mancheſter, Cheſter, Hull, London, &c.

Conway River. This river has nearly a ſouth courſe for

14 or 15 miles, between the counties of Caernarvon and Denbigh in North Wales; its principal object ſeems to be the ſupply of Llanrwſt and Aberconwy, which are conſiderable towns. It commences at the tide-way in Conway bay, and terminates at Llanrwſt town. In June 1802, it was in contemplation to ſtraighten the courſe of this river, about a mile below Llanrwſt, by a new cut 492 feet long, 88 feet broad at top, and 60 at bottom, with a dam at its upper end acroſs the old crooked channel. At Llanrwſt, there is a curious ſtone bridge of three arches, built by *Inigo Jones*, over this river; and in 1802, it was propoſed to conſtruct a ſtupendous caſt iron bridge over it at Aberconway ferry, in order to facilitate the communication with Ireland by way of Holyhead, in the Iſle of Angleſea; another iron bridge being intended at Bangor ferry, on *Menai* ſtrait.

Coombe-Hill Canal. Act 32 Geo. III.—The courſe of this canal is nearly S. E. for $3\frac{1}{2}$ miles, in the county of Glouceſter: its general objects are the export of coals from the mines near it, and ſhortening of the length of land carriage to Cheltenham, which is a conſiderable town; and ſo is Tewkſbury near its weſtern end. It commences in the *Severn* river at Fletcher's leap in Dearhurſt, and terminates at Combe hill in the pariſh of Leigh, the riſe being 15 feet only. This canal was conſtructed at the ſole expence of three perſons, viz. *Thomas Burges*, *William Miller*, and *Sarah Mumford*.

*Cottingham and Hull.* In the year 1802, this line of canal was propoſed, about four or five miles in length, in a N.W. direction, in the eaſt riding of Yorkſhire, to commence in the *Humber* river at the town of Hull, and extend to the town of Cottingham. The import of coals, deals, &c. and the export of farm produce, and perhaps of chalk, ſeem to be its principal objects. Hull is the 16th town in Britain, with a population of 29,516 perſons.

Coventry Canal. Acts 8, 25, (for *Trent and Merſey*) and 26 of Geo. III.—The general direction of this canal is nearly S.E. for about 22 miles (excluſive of the detached part beyond the *Birmingham and Fazely* canal, and the branch to Coventry) in Staffordſhire and Warwickſhire. Its ſituation is high, particularly the eaſtern part, which croſſes the grand ridge near Bedworth, without a tunnel, and its Seeſwood branch does the ſame. Its general objects are the line of communication between London, Birmingham, Mancheſter, Liverpool, &c. the export of coals from the numerous mines near it, and the ſupply of Coventry city, which is the 24th on the liſt of Britiſh population, with 16,034 inhabitants. Nuneaton, Atherſtone, and Tamworth, are alſo conſiderable towns near the line; and Hinckley, the 120th, with 5,070 inhabitants, is alſo in its vicinity. It commences in the *Birmingham and Fazely* canal at Fazely, and terminates in the *Oxford* canal at Longford; its detached part of $5\frac{1}{2}$ miles in length, commences at the termination of the *Birmingham and Fazely* canal at Whittington brook, and terminates in the *Trent and Merſey* canal at Fradley heath; near to Whittington brook, it connects with the *Wyrley and Eſſington* canal, and at Marſton bridge the line is joined by the *Aſhby-de-la-Zouch* canal. There is a cut of about one mile in length to Griff collieries, belonging to ſir Roger Newdigate; another to ſeveral collieries by different branches near Seeſwood-pool and Bedworth, five or ſix miles in length; there is alſo a cut of half-a-mile from the line to Bedworth; the branch to Coventry is $4\frac{3}{4}$ miles in length, and there is a rail-way branch to Oldbury coal works. The detached part is level with the *Trent and Merſey* canal, which level continues (through $5\frac{1}{2}$ miles of the *Birmingham and Fazely*) to the commencement of the line of this canal at Fazely; from thence to Atherſtone, a diſtance of about 10 miles, the riſe is 96 feet, by means of 13 locks; from thence to the *Oxford* canal, about 12 miles, is level; ſo is the cut to Coventry, and thoſe to Griff, Seeſwood-pool, Bedworth, &c. The laſt or higheſt level of this canal forms, with part of the *Oxford* and *Aſhby* canals, the longeſt level that is to be found in Britain, being upwards of 82 miles, we believe, including ſide branches. This is a narrow canal, but the company have bound themſelves to widen the ſame to the width of the *Grand Junction*, if the proprietors of that canal ſhall at any future time require it. A ſtop-gate is maintained at the end of the *Oxford* canal at Longford, to prevent this canal, which is ſometimes low in Summer, from drawing off their water. Mr. *James Brindley* was the original engineer to this concern, and $16\frac{3}{4}$ miles of the level part from Coventry to Atherſtone was completed in 1786, when the works were ſuſpended for near 10 years; at length, the *Trent and Merſey* company undertook to complete 11 miles of this original line north of Fazely; half of which they afterwards ſold to the *Birmingham and Fazely* company; and the other half, on the 4th of February, 1787, was purchaſed by this company, who thus came to have a detached part of their canal. The line of communication was opened by the completion of this canal in June 1790. This company have been authoriſed to raiſe 120,000l., their ſhares being 100l. each. Some years after the completion of this and the *Oxford* canal, the ſhares herein had obtained the great price of 400l., but owing to the rivalry of the *Warwick and Napton* canal, they were, in 1802, reduced to 350l., and their dividend to 8l. per cent. Since the completion of the *Grand Junction*, this concern has been flouriſhing, and the dividends are now 16l. per annum per ſhare. The tonnage allowed on this canal is $\frac{1}{2}$d. per ton per mile for lime and lime-ſtone, and $1\frac{1}{2}$d. per ton per mile for all other articles, (except road or paving materials and manures upon the pounds, or when the water runs to waſte at the locks.) On the completion of the adjoining canals, the tonnage on coals was, by their general conſent, reduced to 1d per ton per mile upon ſeveral of them. It was agreed, between this and the *Oxford* company, (9 Geo. III. *Oxford*) that the latter ſhould be entitled to all tolls, except on coals, that are collected on the firſt $3\frac{1}{2}$ miles of this canal towards Coventry, for goods paſſing from the *Oxford* canal, and that this company ſhould in return receive the tolls upon coals collected on the firſt 2 miles of that canal. The act of 34 Geo. III. for *Aſhby-de-la-Zouch* canal, granted to this company 5d. per ton upon all goods (except farming produce, manures, or road materials, or iron or its ore, made or dug on the banks of the *Aſhby* canal) navigated thereon, which ſhall, either before or after, paſs on any part of this canal, or the *Oxford* or *Grand Junction*; and a farther ſum per ton, equal to the tonnage hereon between Griff and Longford, on all goods which may paſs any new communication that may hereafter be opened between the *Aſhby* canal and the *Oxford* or *Grand-Junction*; for enforcing which, this company is empowered to erect toll-houſes and ſtop-bars, and place collectors on any part of the *Aſhby* canal.

Cree River. The courſe of this river is nearly north, for 9 or 10 miles of a crooked courſe, between the counties of Wigton and Kirkcudbright in Scotland; its object is the ſupply of the adjoining country, and of Wigton, which is a conſiderable town. It commences in the tide-way in Wigton bay in the Iriſh or Northern Channel, and terminates at Newton Douglas.

Crinan Canal. Acts 33, 39, and 45 of Geo. III.—The courſe of this very wide and deep canal is nearly weſt for about nine miles, in the county of Argyle in Scotland; its ſole object is the ſhortening of the paſſage for ſhips between the Iriſh Sea and the *Clyde* river (by means of the loch of Fine), by avoiding the voyage round the peninſula of Kintire. It commences at loch Gilp, and terminates in lock Crinan. The riſe is 58 feet, and the fall 59 feet, a rivulet near the point of diviſion ſerving as its feeder. The water in this canal is 12 to 15 feet deep. This line of canal was firſt ſurveyed for ſmaller veſſels by Mr. *Watt*, after which Mr. *John Rennie* was employed herein; it appears to have been opened ſome time, but farther improvements, and the building of a pier in Loch Gilp are yet in hand. The proprietors have been authoriſed to raiſe 180,000l., and they have alſo received 50,000l. of the public money, which parliament granted in aid of this great and important work. The ſhares are 50l. each. A veſſel under ſail, not being ſtopped in proper time, before ſhe arrived at a lock on this canal, bore the ſame away, and went down therewith into the next pound. A paſſage may, it is ſaid, be made by means of this canal in three or four days, which frequently took up three weeks. In 1802 the ſhares herein were 22l. below par.

Cromford Canal. Act Geo. III.—The general direction of this canal is about N.W. for 18 miles, in the counties of Nottingham and Derby; it is conſiderably elevated: its general objects are the export of coals and of lead, iron, lime-ſtone, and other minerals from the mines of Derbyſhire. Wirkſworth and Belper are conſiderable towns near its courſe. It commences in the *Erewaſh* canal at Langley bridge (not far from the junction of *Nottingham* canal therewith), and terminates in the town of Cromford near Matlock. There is a cut to Pinxton coal works of three miles in length, another to Swanwick coal works; alſo a rail-way branches to Critch lime-works, $1\frac{1}{2}$ mile, and to Biggarlee coal works $1\frac{1}{2}$ mile. From the *Erewaſh* canal to near Codnor caſtle, four miles, there is a riſe of 80 feet, thence to Cromford, 14 miles, it is level; the Pinxton branch is level, and proceeds from the upper level. The width of this canal at top is 26 feet; the boats are 80 feet long, $7\frac{1}{6}$ feet wide, and $3\frac{1}{3}$ feet deep; when empty they draw 8 or 9 inches of water, and when loaded with 22 tons, they draw about $2\frac{1}{2}$ feet. Near Ripley is a tunnel of 2966 yards in length, which is 9 feet wide withinſide at the water's ſurface, and 8 feet high from thence to the crown of the arch, which is of brick, except ſome parts where the rock proved hard and ſound enough to ſtand without walling: the ſide-walls and crown of this arch ſeem to be part of an ellipſis, but where an inverted or bottom arch was wanted, the ſame is much flatter. For conſtructing this tunnel, 33 pits or tunnel-ſhafts were ſunk, ſome of them on the ſummit of the hill, being 57 yards deep. This tunnel is ſaid to have coſt 7l. per yard in length: it interſects a valuable ſeam of coals, which is now worked, and in ſinking the tunnel-pits excellent iron ore was found, which is now worked, and the furnaces are ſupplied with coals drawn up through a ſhaft from below for that purpoſe. There are ſeveral ſmaller tunnels upon the line for ſhortening its courſe. Near Butterly hall there is a conſiderable deep-cutting, and ſhorter ones in other places, to avoid the loops round the points of the hills. Over the Derwent river, near Wigwell, there is a large aqueduct bridge 200 yards long and 30 feet high, the river arch is 80 feet ſpan. Two ſmaller arches by its ſide ſerve to carry off floods, and for a road. Over a ſmall river, which comes into the Derwent near Frithly, is another large aqueduct bridge about 200 yards long and 50 feet high; beſides the river arch, there are two others, one for floods, and another conveys the turn-pike road under the canal; theſe two aqueducts are ſaid to have coſt about 6000l. There are conſiderable embankments in ſome places on this canal. Nearly over the Ripley tunnel there is a reſervoir of 50 acres of water when full, the head or embankment of which is 20 yards long, 33 feet in height in the middle of the valley, the baſe being there 52 yards wide, the top of the bank is four yards wide. This reſervoir is ſaid to have coſt 1600l.; the mean depth of it is 12 feet, and it will contain about 2[illegible] locks full of water, which is let out by a large pipe and cock in one of the tunnel-pits. There are two other reſervoirs for this canal, one of 20, the other of 15 acres. At the Cromford end of the canal there is a conſiderable ſtream of water taken in as a feeder, and the whole of the 14 miles of level and branches thereto have their banks made up one foot higher than uſual to act as a reſerve for dry weather. Mr. *William Jeſſop* was the engineer to this canal, and it was completed before the year 1794. The total coſt is ſaid to have exceeded 80,000l. For the cutting and wheeling of clay, $3\frac{1}{2}$d. per cubic yard, per ſtage of 20 yards, was uſually paid; for gravel $4\frac{1}{2}$d. per yard; for ſtony ground $4\frac{1}{2}$d. per yard, and 4d. per cubic yard extra for all ſtones picked out and ſtacked. In the year 1797, a cut was propoſed from the ſummit-level to the new collieries in Codnor park. In 1801, notices were given for the intended *Belper* canal, that was propoſed to join this near to Bull bridge; and in 1802, a cut was propoſed to be made from the Derwent aqueduct on this canal to near Dethick, and thence near the Derwent and Wye rivers to the town of Bakewell.

Crouch River. The courſe of this river is nearly weſt, in the county of Eſſex. The principal objects of this navigation are the import of coals, deals, &c. and the export of farm produce, and of oyſters from near Walfleet. Billerica and Rochford are the neareſt conſiderable towns to this river. It commences in the Engliſh channel (about 10 miles from the mouth of the *Thames*), and terminates at Hull bridge.

Croydon Canal. Act 41 Geo. III.—The general direction of this canal is nearly ſouth for $9\frac{1}{2}$ miles, in the counties of Kent and Surrey: it is not greatly elevated; its objects are the ſupply of Croydon with coals, deals, &c. and the country through which it paſſes with manures and other articles, and the conveyance of its produce to the London markets, and the export of fire-ſtone, flint, and fullers' earth. Croydon is the 108th Britiſh town, with a population of 5,743 perſons. Deptford is alſo a conſiderable place. This canal commences in the *Grand Surry* canal near Deptford (two miles from its connection with the *Thames* at Rotherhithe), and terminates at the new Baſon near the town of Croydon. From the *Grand Surry* canal (level with an ordinary high tide in the *Thames*) to the top of Plowgarlic hill, $1\frac{1}{4}$ mile, is a riſe of 70 feet, by 12 locks; thence for $\frac{1}{2}$ a mile it is level, and thence for $\frac{3}{4}$ of a mile to the beginning of Foreſt wood, there is a riſe of $79\frac{1}{2}$ feet, by 13 ſingle and one double locks; from thence to Croydon, 7 miles, it is level. The locks upon this canal are 60 feet long and 9 feet wide; each lock has a groove for ſtop-planks at its head, but no paddle-weirs; the waſte water is intended to run over the upper gates. This company are to have a baſon for their boats to lie in at Rotherhithe, on the ſouth-eaſt ſide of the *Grand Surry* entrance baſon, and another by the high road near Croydon town. There are ſeven road bridges and 30 accommodation ſwing-bridges. On the top and northern ſlope of Plowgarlick hill, there is a conſiderable deep-cutting, and others in Sydenham and on Penge common; and near Selhurſt wood is a conſiderable embankment. On Sydenham common there is a reſervoir of 10 or 15 acres ſupplied in wet times by a feeder out of an adjoining vale, and into which its waſte or over-fall is to be when full; there is another reſervoir on Norwood common, which, with the long ſummit-pound on ſo tenacious a ſoil, will be ſufficient, it is preſumed, to ſupply the locks that are making. At the time the act paſſed for this canal, it ſeemed intended to uſe inclined planes, and to pump the water for ſupplying the pounds up from the *Grand Surry* canal by ſteam-engines, that were alſo intended to wind the boats up the planes: and it ſeems ſingular, under theſe circumſtances, that legiſlative proviſion was made, for a culvert or ſmall tunnel through Foreſt-hill for conveying water from the ſummit-level of this canal on Sydenham common, and by aqueducts or pipes to ſupply ſeveral towns and places with water, viz. by a branch of near $\frac{3}{4}$ of a mile to the top of Dulwich town, and from the end of the ſaid tunnel to Knight's hill by a crooked courſe of three miles in length through Norwood, and along Knight's hill towards London for one mile; alſo another branch of near one mile to Streatham town. Mr. *John Rennie* and Mr. *Ralph Dodd* were the engineers, and Mr. *Clark* is now employed as reſident engineer thereon. About ſeven miles of the upper end of this canal is completed and in uſe, and the remainder is proceeding with great expedition. The company are empowered to raiſe 80,000l., which is not now expected to prove ſufficient; the amount of ſhares are 100l. each. The ſum of 40l. is to be paid annually to the city of London, towards improving the Thames river above London Bridge. This canal is to have its water kept always two feet above the ſurface of the ground on Croydon common, and ſome other ſevere and unprecedented reſtrictions are introduced in favour of the millers on the Wandle river, at ſome miles diſtance.

*Croydon and Wandſworth.* In September 1800, propoſals were made for a canal from the river *Thames* at Wandſworth, following nearly the courſe of the Wandle river to Croydon in Surry; but the ſame was given up ſhortly after, in favour of the north *Surry iron rail-way*, which paſſes through nearly the ſame tract.

CYFARTHFA CANAL. The general direction of this canal, or *water level*, is nearly N.W. we believe, for about 3 miles, in the county of Brecknock; it is on a high level, and was conſtructed ſome years ago by Mr. *Bacon*, to bring coals and iron-ore from the mines in the mountains, to his furnaces at Cyfarthfa, near Merthyr Tidvil. The whole is upon one level, and it does not connect with any other canal or navigation; it is now the property of Mr. *Crawſhaw*, the great iron maſter. It is ſituate near to the northern ends of the *Glamorganſhire* canal and the *Cardiff and Merthyr* rail-way.

DARENT RIVER. The courſe of this river (called Dartford creek,) is ſouth for near 3 miles in the county of Kent; it commences in the tide-way in the river *Thames*, and terminates near the town of Dartford, for whoſe ſupply it is principally uſed.

DART RIVER. The general direction of this river is nearly N.W. for about 10 miles, in Devonſhire; the tide flows through its whole length; its principal objects ſeem to be the ſupply of Totneſs with coals, and the country with ſhell-ſand manure, and the export of farming produce. Dartmouth and Totneſs are conſiderable towns; its commencement is in Start bay, and it terminates at the Mill weir, about one mile above Totneſs; this river is plentifully ſtored with trout.

*Dean-Foreſt Rail-way.* In the year 1802, it was propoſed to conſtruct a rail-way from the river *Wye*, near to Engliſh Bichnor, we believe, to the ſummit of the Foreſt of Dean, its object being the carriage of the immenſe ſtores of coal and iron, with which it abounds; Colford is a conſiderable town near its route. In the preceding year the *Severn and Wye* rail-way was propoſed to paſs nearly the ſame track.

DEAN RIVER. Act 12 Geo. III.—The direction of this river is nearly S. for about 2 miles, in the county of Nottingham; it is not greatly elevated above the level of the ſea; its principal object is the ſupply of Newark, the 91ſt town in the liſt of Britiſh population, with 6730 inhabitants. It commences in the river *Trent*, at Crankley's, in South Markham, and terminates at the upper weir near the town of Newark; the works hereon were completed in Jan. 1797. In 1793 the *Newark and Bottesford* was propoſed to join this at Newark.

DEARNE AND DOVE CANAL. Acts 33 and 40 Geo. III. —The general direction of this canal is about N.W. for $9\frac{1}{4}$ miles, in the Weſt Riding of Yorkſhire, its northern end is conſiderably elevated; its objects are the communication between Sheffield, Wakefield, Halifax, Leeds, Mancheſter, Liverpool, &c. and the export of the coals and iron-ſtone, &c. ſo plentifully found on its courſe. Barnſley and Rotherham are conſiderable towns on or near it, ſo is Doncaſter, the 110th town, with 5697 inhabitants. It commences in a ſide cut of the *Don*, or Dun river, between Swinton and Mexburgh, and terminates in the *Barnſley* canal at Eyming's wood, near Barnſley, there is a branch of $3\frac{1}{8}$ miles to Rockcliff bridge, and another of $1\frac{3}{4}$ miles to Cobcar Ing. From the cut of the *Don* navigation to Knoll Brook the diſtance is $4\frac{1}{4}$ miles, with a riſe of $41\frac{1}{4}$ feet; thence to Aldham Mill, $2\frac{1}{8}$ miles, is a riſe of 24 feet, (the Cobcar Ing branch being on its higheſt level); thence to the *Barnſley* canal is $2\frac{7}{5}$ miles, with a riſe of $59\frac{2}{3}$ feet; the Cobcar Ing branch is level; the Rockcliff branch begins from the ſummit-level, and $1\frac{1}{2}$ mile to Worſborough bridge is level; thence to Rockcliff bridge, $1\frac{5}{8}$ mile, it has a riſe of 56 feet. The locks on this canal are built with excellent hewn or aſhler ſtone, and are calculated for boats of 50 or 60 tons burthen, the ſame as navigate the *Dun* river, and this company are required to keep a depth of water equal to $4\frac{1}{2}$ feet on their lock-ſills, and in every part of their line; and for guarding againſt loſs of water on the ſummit, a ſtop-gate is to be erected hereon, near the termination in the *Barnſley* canal, and another on that canal below the junction, both of which may be ſhut and locked when the ſupply of either canal fails, and it would conſume the water of the other. The aqueduct and other bridges hereon are ſubſtantially conſtructed of hewn ſtone. Tumbling-bays and gauge-weirs are to be erected for ſupplying ſeveral mills. There is a large reſervoir near Elſicar. Proprietors of mines may make rail-ways to this canal, if within 1000 yards, or 2000 yards near Wath. Mr. *John Thompſon* is ſaid to have been the engineer, and it was completed in the year 1804. The company were empowered to raiſe 100,000l. The amount of ſhares 100l. each. The rates of tonnage on this canal are too various and complicate for the room we can allot to this ſubject, they will be found in *Phillips' 4to. Hiſtory*, p. 62 to 66; but it muſt be obſerved, that the laſt act (40 Geo. III.) made an increaſe of, we believe, 50 per cent. on theſe tolls. Boats are to pay for 6 miles of tonnage, however ſhort a diſtance they may have navigated on this canal. In May 1797, earl Fitzwilliam propoſed, at his own expence, to extend the Cobcar Ing branch to his Elſicar collieries, on being allowed water for the ſame from the Elſicar reſervoir.

DEBEN RIVER. The courſe of this river is nearly N.W. for about 10 miles, in the county of Suffolk; its objects are the imports of coals, deals, &c. and exports of farm produce; it commences at the ſea near Felixtow, and terminates near Woodbridge, which is a conſiderable town.

DEE RIVER, (*Aberdeen*). This river takes its courſe about weſt for 2 miles, between Aberdeenſhire and Mearns county in Scotland, the tide flowing through the whole navigable length; it commences in the harbour of new Aberdeen, where it is joined by the *Aberdeenſhire* canal. New Aberdeen is the 19th town in Britain, with 17,597 inhabitants, and its harbour was improved by a pier of 300 yards in length, begun under the direction of Mr. *John Smeaton*, in 1770, who was employed again in 1778, to make farther improvements. In 1801, Mr. *Thomas Telford* was employed to deſign new works and improvements hereon, ſo that ſhips of 18 or 20 feet draught of water may be accommodated. There are excellent granite quarries near this river.

Dee River, (*Cheſter*). The general courſe of this river is nearly S.E. for about 22 miles, in the county of Flint, and ſkirting the county of Cheſter: the firſt 9 miles are by a wide eſtuary opening to the Iriſh channel, and from near the town of Flint thereon, a new cut was made for the river up to Cheſter, under the direction of Mr. *Nathaniel Kinderley*, about the year 1749; before which time the old channel was ſo choaked with ſand, that ſhips of burthen could not come within 7 or 8 miles of Cheſter; the new ſtraight cut, that was at firſt 8 feet deep in general, principally through marſhes, ſoon ſcoured itſelf out, ſo that ſhips of 200 tons could come up to the town, and where the time of high-water became earlier by $\frac{3}{4}$ of an hour, than when the tide had to make its way through the old crooked and ſhallow channel. Cheſter is the 25th town, with 15,052 inhabitants, Holywell near it, is the 111th, with 5,567 perſons, and Flint is alſo a conſiderable town. On the N.W. ſide of Cheſter the *Elleſmere* canal connects with this navigation and croſſes it, for which goods pay 2d. per ton to this company; it is alſo to receive from the *Elleſmere* company whatever its tolls may fall ſhort of 210l. annually. At Cheſter this river is joined by the *Cheſter* canal.

Dee River, (*Kirkcudbright*). The courſe of this river is nearly N. for about 6 miles, in the county of Kirkcudbright in Scotland, being an eſtuary opening to the Iriſh ſea. Kirkcudbright is a conſiderable town thereon, and where the *Glenkens* canal connects therewith.

Derby Canal. Act 33 Geo. III.—This canal runs nearly N. for about 9 miles, in the county of Derby; it is not greatly elevated above the level of the ſea. Its objects are, the ſupply of the town of Derby, and the export of coals and iron. Derby is the 43d Britiſh town, with a population of 10,832 perſons. It commences in the *Trent* river at Swarkſtone bridge, croſſes and interſects with the *Trent and Merſey* canal, and terminates at Little Eaton, near 4 miles above Derby, from which town a cut of $8\frac{1}{2}$ miles goes off to a place between Sandiacre and Long Eaton, and there joins the *Erewaſh* canal. There is a *rail-way* branch of $4\frac{1}{2}$ miles, to Smithey-houſes near Derby, another to Horſley collieries, and another of $1\frac{3}{4}$ mile to Smalley mills. In caſe a rail-way, or canal, ſhould be hereafter made S. of the *Trent* from Bredon lime-works, this company has engaged to make a cut between the *Trent and Merſey* canal and the *Trent*, at Weſton cliff, oppoſite thereto. From the *Trent* to the *Trent and Merſey*, $\frac{1}{2}$ a mile, is a riſe of — feet; thence to Derby, $5\frac{1}{4}$ miles, is a riſe of 12 feet; and thence to Little Eaton, $3\frac{1}{4}$ miles, is a riſe of 17 feet; the *Erewaſh* branch has a fall of 29 feet. This canal is 44 feet wide at top, 24 at bottom, and 5 feet deep, except the upper level next Little Eaton, which is made 6 feet deep to retain the water of wet ſeaſons like a reſervoir; the locks are 90 feet long, and 15 feet wide within ſide: adjoining the town of Derby is a prodigious large weir or tumbling bay, where the canal croſſes the *Derwent* river, that was navigable to this place for many years back, but the tolls thereof were expected to fall off on the completion of this canal, and it was therefore agreed, that this company ſhould purchaſe the whole concern for 3996l. A little W. of the river above-mentioned, the canal croſſes a brook in a *caſt iron* trough or aqueduct. This canal was finiſhed in 1794; the company were authorized to borrow 90,000l. the value of ſhares being 100l. Separate rates of tonnage were fixed on different goods, between the *Trent* and the *Trent and Merſey*, between that and Derby, and on the different cuts and rail-way branches, which are too long for us to inſert, they will be found in *Phillips' 4to. Hiſtory of Canals, Appendix*, p. 55 to 59. Manures are to paſs toll-free, and puncheons or clogs of wood, to be uſed as ſupports in the adjacent coal-mines, alſo road materials, except for turnpike-roads; and if the Mansfield turnpike-road tolls are reduced below 4 per cent. on their debt, this company is to make them up to that ſum. The profits of this concern are not to exceed 8 per cent. but after 4000l. is accumulated as a ſtock for contingencies, the tolls are to be reduced. Five thouſand tons of coals annually are to paſs hereon toll-free, for the ſupply of the poor of the town of Derby. Horſes pay 1d. and cattle $\frac{1}{2}$d. each, for liberty of paſſing along each rail-way branch.

Derwent River, (*Derby*). The courſe of this river is nearly N.W. for about 9 or 10 miles, in the county of Derby; its principal object was the ſupply of Derby, previous to the making of the *Derby* canal, when this concern was ſold to that company, as mentioned above. It commenced in the *Trent* river at Wilden-ferry, (where the *Trent and Merſey* canal commences,) and terminated at the town of Derby.

Derwent River, (*New Malton*). The general courſe of this river is nearly N. for about 37 miles, in the Eaſt Riding of Yorkſhire; its objects are the ſupply of New Malton (a conſiderable town) with coals, deals, &c. and the export of farm produce, chalk, &c. It is but little elevated above the ſea; it commences in the *Ouſe* river at Barnby, and terminates at the town of New Malton. In January 1804, it was in contemplation to make this river navigable up to Yedingham bridge.

Derwent River, (*Workington*). The courſe of this river is nearly E. in Cumberland. Workington, on its banks, near the Iriſh ſea, is the 109th Britiſh town, with 5,716 inhabitants; to the vicinity of this town there are ſeveral *rail-ways*, which bring down coals from Mr. *Curwen's*, and other coal-mines, for exportation from this place.

Devon River. The general direction of this river is nearly N.E. in Clackmannanſhire in Scotland, from near Cambus quay, on the Frith of *Forth*, (two and a half miles above Alloa) to Medlockfoot. Mr. *John Smeaton* was, in 1765, and again in 1768, conſulted, about making this river navigable, or a canal by its ſide, the riſe being $38\frac{1}{2}$ feet, in order to bring down the produce of ſeveral coal-mines near its banks, to be ſhipped on the *Forth*, wherein the ſpring tides riſe 20 feet at Cambus quay. A branch was propoſed to Alloa, and another to Sterling.

Dewsbury and Birstal Rail-way. The general direction of this rail-way is nearly N. for about 3 miles, in the Weſt Riding of Yorkſhire, and its object is to bring down coals to the veſſels in the *Calder* river; it commences in the *Calder and Hebble* navigation at Dewſbury, and terminates at Stubley coal-mines in Birſtal pariſh, which are worked by Meſſrs. *Thomas Cheſter* and Sons, who are alſo the ſole proprietors of this iron rail-way, which was completed in the preſent month (October 1805).

Don, (*or Dun*) River. Act 12 Geo. II. The general direction of this river is nearly S.W. for near 40 miles in the Weſt Riding of Yorkſhire, (including what is, in ſome maps, called the Dutch river, near to the *Ouſe*,) the ſouthern end of this navigation is rather elevated. The original objects of this navigation were principally the ſupply of Sheffield, and the export of the iron-wares and iron from Sheffield, Rotherham, &c. ſince which period, the *Dearne and Dove* canal, which joins at Swinton, and the *Stainforth and Keadby*, at Fiſhlake and at Hangman Hill, and the cut to the *Ayre* river near Snaith, have opened new ſources of ſupply, and for the export of coals, ſtones, iron, and manufactured goods of ſeveral kinds, which this rich track of country produces. Sheffield is the 14th Britiſh town, with 31,314 inhabitants, Doncaſter is the 110th with 5697 perſons; Rotheram, Doncaſter, Thorne, and Snaith are alſo conſiderable towns on or near this navigation. The commencement is in the *Ouſe* river, at Goole bridge, and it terminates at Attercliffe, within 2 miles of Sheffield, and has a cut to the *Ayre*, as above, and ſide-cuts with locks between Mexburgh and Swinton, and in other places; the tide flows above the junction of the river Went. The *Stainforth and Keadby*, act 33 *Geo.* III. has directed rates for boats paſſing out of this into that canal by the cut of this river. In September 1803, notices were given, for a new act for weirs and ſide-cuts to this river in Mexborough, Spotborough, and other places, and a new courſe for the river, near the junction of Dearne river. And, in February 1803, there was a deſign of extending this navigation to Sheffield by a canal from Tinſley, 4 miles, for which 30,000l. was ſubſcribed.

DONNINGTON-WOOD CANAL. The general direction of this canal is about N. or N.E. for 7 miles in Shropſhire; it is upon a very high level, nearly parallel to the grand-ridge on the weſtern ſide: its object is the conveyance of iron-ſtone and lime-ſtone, from the mines to the Donnington-wood iron works in Lileſhal pariſh, and lime and coals for the ſupply of the town of Newport, which is a conſiderable place. It commences in the *Shropſhire* canal (near its junction with *Shrewſbury* canal,) at Donnington wood, and terminates at Pave-lane wharf near Newport; it has a level branch to Lileſhal lime-works, but on a higher level than the line, to which the lime-ſtone was formerly let down, in boxes through perpendicular ſhafts, at the ſame time that other empty boxes were aſcending, the conſtruction being nearly the ſame as the ſhafts afterwards uſed at Brierly-hill on the *Shropſhire* canal, but like them they have ſince been diſuſed and inclined planes are now uſed, on which boxes of lime-ſtone deſcend and draw up empty boxes by means of ropes paſſing over a large drum, to which a brake-wheel is adapted to regulate the motion. The boats hereon carry 25 tons of lading: the canal was cut in 1778 at the joint expence of the marquis of *Stafford* and Meſſrs. John and Thomas Gilberts. In June 1797 this was propoſed to be joined at Pave-lane by the *Newport and Stone* canal.

DORSET AND SOMERSET CANAL. Acts 36 and 43 Geo. III.—The general direction of this canal is nearly S. for about 40 miles in the counties of Wilts, Somerſet, and Dorſet: the middle part of it is on a high level, and croſſes the ſouth weſtern branch of the grand ridge. Its principal objects are the ſupply of the manufacturing towns and neighbourhood through which it paſſes, with coals from the mines bordering on Mendip, and the opening of an inland communication between the Briſtol channel, the *Severn*, the *Thames*, and the ſouthern coaſt of the iſland. Froome is the 60th town in the order of population, with 8,748 inhabitants, and Bradford, the 78th, with 7,302 perſons; Bruton, Wincanton, Stalbridge, and Sturminſter are alſo conſiderable towns near the line. The commencement is in the *Kennet and Avon* canal at Widbrook near Bradford, and the termination in the *Stour* river near Gains-croſs in Shilling-ſtone-Okeford; from near Froome a branch of about 9 miles proceeds to Nettlebridge collieries in Midſummer-Norton. The Nettlebridge branch was firſt cut, in order to ſupply coals to Froome and its neighbourhood; and water being ſcarce thereon, one of Mr. *Fuſſel's* balance-locks was erected on a 21 feet fall at Mells near Froome, and was publickly tried on the 6th of September, and 13th of October 1800, and in June 1802, as particularly deſcribed in a previous part of this article. An aqueduct bridge was erected ſeveral years ago over the river near Froome, but it is with ſlow pace, we fear, that the works are proceeding towards a final completion. The company were by the firſt act authoriſed to raiſe 225,000l. and a further ſum under the ſecond, we believe, the amount of ſhares being 100l. Stones are to be erected at every half mile: pleaſure-boats of 12 feet long and 5 broad may be uſed on the pounds, 30 yards in width are allowed, in general, for the company to purchaſe, and 100 yards wide for docks, wharfs, &c. ſprings may be taken and reſervoirs formed any where within 2000 yards of this canal.

DOUGLAS RIVER (*Lower Navigation.*) Acts 6 Geo. I. and 10 and 23 Geo. III. (for *Leeds and Liverpool*). The courſe of this navigation is nearly ſouth; for 9 miles in Lancaſhire it is but little elevated above the ſea; its objects are the export of common and cannel coals, and farm produce, and the import of lime-ſtone; it commences in the tide-way in the eſtuary of the *Ribble* river near Haſketh, and terminates in the *Leeds and Liverpool* canal at Brier's Mill. From the *Ribble* to Solom, about 5 miles, the river Douglas (or Aſland) is navigable, and thence to Brier's Mill is a canal 4 miles, with a riſe of 8 locks, the whole riſe from the *Ribble* being 49 feet. The width of the canal is 24 to 30 feet, and depth of water 5 feet; the locks are 70 feet long, and 15½ feet wide. The firſt act above authoriſed Meſſrs. *William Squires* and *Thomas Steers* to make the *Douglas* river navigable from the Ribble to Miry-lane end, near Wigan, which they effected about the year 1727; being allowed 2 s. 6 d. per ton for goods, whatever diſtance they might be navigated thereon; by the firſt act for the *Leeds and Liverpool* canal (10 Geo. III.), their ſucceſſors were authoriſed to make a junction with the *Leeds and Liverpool* canal at Newborough by a cut of 3½ miles long, parallel to this river, with a fall of 12 feet, which they completed in 1774, and the ſame now forms part of the *Leeds and Liverpool* canal, S.E. of Newborough aqueduct bridge, in conſequence of the purchaſe which that company made of the whole of this concern, in purſuance of their act of 23 of Geo. III.; ſince which, the canal from Brier's Mill to Solom above deſcribed, as part of the lower navigation, was cut and completed in 1781, and the river navigation between Solom and Wigan, 12 or 13 miles (on the upper navigation) has, we believe, been diſuſed ſince the *Leeds and Liverpool* canal was completed by its ſide to Wigan, and the communication by the lower *Douglas* navigation to the *Ribble*, above deſcribed, was opened.

DOUGLEDGE RIVER. The courſe of this river is nearly north in the county of Pembroke in South Wales, from the tide-way in *Milford-Haven* to Haverfordweſt bridge, its object being the ſupply of that town.

DRIFFIELD CANAL. Acts 7 and 41 of Geo. III. The courſe of this navigation is nearly north, for about 11 miles in the Eaſt Riding of Yorkſhire; it is but little elevated above the ſea; its general objects are the import of coals, deals, &c. and the export of farming produce; it commences at Aike-beck mouth in the *Hull* river, and terminates at the town of Great Driffield; the firſt five miles is by the courſe of the *Hull* river to Fiſh-holm clough, and the remaining 6 miles is by a canal; the courſe of the *Hull* river ſerves alſo as a branch of 1½ mile in length to Frodingham bridge. In 1764 Mr. *John Smeaton* was conſulted on this intended navigation.

gation. In 1804 it was in contemplation to deepen the Frodingham branch, and about 2 miles of the canal up to Snakeholme lock, nearly 2 feet deeper than it was before.

DROITWICH CANAL. Act 8 of Geo. III. The general direction of this canal is about N.E. for 5¼ miles in the county of Worceſter; it is not greatly elevated above the ſea; its objects are the export of ſalt and the import of coals, of which 13,500 tons are annually imported, and uſed in the boiling of ſalt, except what the town of Droitwich conſumes. It commences in the river *Severn*, at Hawford, and terminates at Chapel bridge in the town of Droitwich; it has a riſe of 59½ feet by 8 locks. This canal was executed by Mr. *James Brindley*, and it is ſaid to preſent a pattern to canal-makers by the neatneſs and regularity of its curves, and the ſtability and excellency of all its works. The proprietors were authoriſed to raiſe 33,400l. the amount of ſhares being 100l. The tonnage on every quarter of grain, or 6 buſhels of meal, is 2d. and on every ton of ſalt, coals, or other matters, 1s. 6d. By the act for the *Worceſter and Birmingham* canal (31 Geo. III.), the ſhares herein are guaranteed to produce 5 per cent. annually, and are to be made up by that company in caſe of their falling below that ſum. Owing to the overflowings of the copious ſalt ſprings near Droitwich, this canal preſents the curious ſpectacle of a ſalt-water canal, in the interior of the country, in which no river-fiſh can live.

DROMREAGH CANAL. This is a canal in Ireland, concerning which our information extends no further, than that the parliament of that country, between the years 1768 and 1771, granted 3000l. of the public money towards carrying on the works.

DRUMGLASS CANAL. This is a canal connecting with the Drumglaſs collieries in Ireland, towards the works of which canal, and thoſe collieries, the parliament of that country, between the years 1753 and 1771, granted no leſs than 117,714l. of the public money!

DUDLEY (*and Owen*) CANAL. Acts 16, 25, 30, 33, and 36 of Geo. III. The general direction of this canal is nearly N.W. by a crooked courſe of 13 miles in Worceſterſhire, a detached part of Shropſhire, and Staffordſhire; it is ſituate very high, its two ends are on the eaſtern ſide of the grand ridge, while its middle, by means of two very long tunnels, is on the weſtern ſide of the ſame. Dudley is the 49th Britiſh town with a population of 10,107 perſons, and the buſy and rich country through which this canal paſſes, furniſhes an ample tonnage in the export of coals, iron, and lime, while its communication with the *Stourbridge* canal, by the Black-Delph branch, and the terminating canals, occaſions a very conſiderable carrying trade thereon. This canal commences in the *Worceſter and Birmingham* canal at Selly Oak, and terminates in the old *Birmingham* at Tipton Green; from near Dudley there is a branch of 2 miles to the *Stourbridge* canal at Black-Delph in Kingſwinford, there is another branch of 1¼ mile to near Dudley town, and a branch from this laſt of ¾ of a mile to Dudley coal-works. From the *Worceſter and Birmingham* canal to the Black-Delph branch, 10½ miles are level, thence to near the entrance of the Dudley tunnel, about ¾ of a mile is a riſe of 31 feet by 5 locks, thence through the tunnel it is level, and from thence, in the laſt ⅛ of a mile, is a fall of 13 feet by 2 locks, to the old *Birmingham* canal: the Black-Delph branch has a fall of 85 feet by 9 locks to the *Stourbridge* canal; the Dudley branch has a riſe of 64 feet in the firſt ¾ of a mile, the remainder thereof being level, and the colliery branch level therewith. The depth of water in this canal is 5 feet; the width of the locks on the Black-Delph branch is 7 feet. To near Lapal, or Laplat, this canal paſſes through a tunnel 3776 yards long, at Gorſty hill it paſſes through another of 623 yards, under a collateral branch of the grand ridge, and at Dudley there is another tunnel of 2926 yards in length on the ſummit-level of the canal; the arch of this laſt tunnel has a height of 13½ feet. At Cradley-pool is a large reſervoir for ſupplying the lockage of the Black-Delph branch. It is provided, that level cuts may be made from this canal towards any coal-mine, to the extent of 2000 yards. A ſtop-lock is erected at the junction with the *Worceſter and Birmingham* canal, by which either company has a power of preventing the other from drawing off their head of water. The Black-Delph branch was firſt executed, which was then united with the Dudley part of the canal which had been conſtructed by lord viſcount Dudley and Ward; theſe were completed and in uſe before the extenſion or main length to Selly Oak was deſigned. The company has been authoriſed to raiſe 229,100l. the amount of ſhares being 100l. each originally. Owing to the different acts under which the parts of this canal were progreſſively undertaken, the rates of tonnage being different thereon, and to the variety of rates on different articles, we cannot attempt an account thereof in this ſhort abſtract, they will be found in *Cary's Inland Navigation*, p. 53 to 55, alſo p. 43, where certain rates are made payable to the old *Birmingham* company on account of the junction therewith, (but which have ſince been varied by the 34 of Geo. III. for *Birmingham* canal) and at p. 70. will be found other rates, in conſequence of the junction with the *Worceſter and Birmingham* canal. In the *Stratford* act (33 Geo. III.) are ſeveral regulations relating to tolls on goods paſſing to or from this canal; and this company are bound to make up the profits of the *Stourbridge* canal to 12l. per ſhare annually, but not exceeding 3l. on each ſhare.

*Durham and Cheſter-le-Street.* In February 1797 Mr. *Robert Whitworth* made a report in favour of a propoſed canal from the *Tyne* to Cheſter-le-Street, and thence to Durham, it was eſtimated to coſt 79,000l. and the probable advantage thereon to ſubſcribers was ſtated to be near 20 per cent. Durham is the 74th Britiſh town, with 7,530 inhabitants; this country abounds in coals.

EDEN RIVER. The general direction of this river is nearly S.E. for about 12 or 13 miles in the county of Cumberland; its principal objects ſeem the export of coals, and the ſupply of Carliſle, which is a conſiderable town. It commences in the tide-way of the *Solway* Firth, and terminates at Carliſle bridge. In 1795, the *Newcaſtle and Carliſle* canal was propoſed to join this river at Carliſle. In 1799 a *rail-way* from the earl of Carliſle's coal-works, near Brompton, to this river, was opened; and in 1803 another was intended from lord Lowther's coal-works at Warnel, about 11 miles diſtant from Carliſle.

EDINBURGH AND GLASGOW CANAL. This canal, projected about the year 1796, appears to have nearly a weſt direction for about 50 miles in the counties of Edinburgh, Linlithgow, and Lanark in Scotland; its objects are the export of coals and lime from Clydeſdale, through which it paſſes, and the opening of a direct communication between Edinburgh and Glaſgow. Edinburgh (and Leith) being the 3d Britiſh town, with a population of 82,560 perſons, and Glaſgow the 5th, with 77,385 inhabitants; from the ſcanty materials to which we have at preſent acceſs, it ſeems that this canal commences in the tide-way of the *Forth*, in the harbour of Leith, and terminates in the tide-way of the *Clyde*, in the town of Glaſgow, and was finiſhed in 1802; that at Glaſgow it connects with the *Monkland*, and in 1803 the *Glaſgow and Saltcoats* was propoſed alſo to join it.

*Eil and Shiel* canal. In the year 1803 Mr. *Thomas Telford* ſurveyed this line of canal, being a length of 3 miles from the tide way in Loch *Eil* within ſome miles of the weſt end of the *Inverneſs and Fort-William*, or Caledonian canal, to Loch Shiel, a freſh-water lake on the Highland coaſt of Scotland; Loch Shiel was found $7\frac{7}{12}$ feet higher than Loch *Eil*, and in order to conduct a 12 feet deep canal out of the former to the ſhore of the latter, it appears that deep cutting will be required, for about a mile to the depth of $47\frac{1}{2}$ feet, there being no water on the ſummit to ſupply a lockage up and down.

ELLESMERE CANAL. Acts 33, two of the 36, 41, 42, and 44 of Geo. III.; the general direction of this canal is nearly ſouth for 57 miles, by a crooked courſe through the counties of Cheſter, Flint, and Denbigh, (North Wales) and Salop; its principal ſummit is conſiderably elevated above the ſea; its great object is ſaid to be the improvement of the agriculture of the extenſive and fertile tracts, through which it paſſes, for uniting the *Merſey*, *Dee*, and *Severn* rivers, and exporting coals, lime, and ſlate, from the ſkirts of the Welſh hills. Liverpool is the 4th Britiſh town, with a population of 77,653 perſons, Cheſter is the 25th with 15,052 perſons, Shrewſbury the 36th with 14,739 perſons, and Elleſmere the 112th with 5,553 perſons; Wrexham, Whitchurch, and Oſweſtry, are alſo conſiderable towns on or near this canal or its branches. This canal commences in the *Merſey* river (9 miles above Liverpool) at Elleſmere-port in Netherpool, and terminates in the *Severn* river at Bagley bridge, very near to the termination of the *Shrewſbury* canal, to which it is propoſed to be joined; at the N.W. part of Cheſter city, it connects with the *Cheſter* canal, and near the ſame place croſſes and connects with the tide-way in the *Dee* river; from near Pulford a branch of 4 miles is propoſed to Holt; from near Gwerſelt a branch of — miles to Talwern coal-works in the pariſh of Mould, near the head of the Cegedog valley, where there is an opportunity of conſtructing a reſervoir of 82 acres to ſupply the ſame (this branch to paſs Frood collieries, Brumbo iron-works, and Nant-y-frith lime-works); another ſhort cut from Greſford to Allington; and a *rail-way* branch to Ruabon-brook; and to the river Dee at Llandinillo; from near Pont-Cyſylty, a branch to Acreſair coal-works; from Francton common, is a branch of about 25 miles paſſing the town of Whitchurch, to the *Cheſter* canal at Stoke in Acton pariſh near Nantwich; from which branch, another of about 7 miles proceeds from Fen-Moſs to Prees Heath; from Hordley on the main line, a branch of near 11 miles proceeds to the line of the *Montgomery* canal near Llanymynech, and the Verniew river; there being from this branch another to the termination of the *Montgomery* canal at Portywain lime-works near Llanyblodwell, and another ſhort one is intended to Marda bridge near Oſweſtry. From the *Merſey* to the *Dee* (ſometimes called the Wirral branch) the diſtance is 8 miles; from the *Dee* river to the Brumbo or Talwern branch it is $11\frac{1}{2}$ miles, with a riſe of 380 feet; thence along the ſummit pound, and through the Chirk tunnel $8\frac{1}{2}$ miles are level; thence to the north end of the great iron-aqueduct, $\frac{1}{2}$ a mile, is a fall of 75 feet; thence to St. Martins moor, 9 miles, it is level; thence to the Whitchurch branch at Francton-common, $2\frac{3}{4}$ miles, is a fall of 13 feet; thence to the Llanymynech line at Hordley is $\frac{1}{4}$ of a mile with 33 feet fall; thence to Ormond park, $14\frac{1}{2}$ miles, is level; and thence to the *Severn* river at Shrewſbury is 2 miles with a fall of 107 feet. The Holt branch is level, the Whitchurch branch to that town, 14 miles, is level, and thence to the *Cheſter* canal, 11 miles, has a fall of 128 feet; the Prees Heath branch is level, the Llanymynech branch, 12 miles, has a fall of 19 feet. The depth of water in this canal is $4\frac{1}{2}$ feet, and the canal in general is calculated for boats of 70 feet long and 7 wide; but the Wirral-branch is formed for boats of 70 feet long and 14 feet wide. There is a tunnel near Chirk of 775 yards in length, and another at Weſton-Lullingfield of 487 yards in length. At Pont-Cyſylty, this canal is carried over the river Dee in an immenſe aqueduct trough, compoſed of caſt-iron plates, 20 feet wide, 6 feet deep, and 320 feet long; this is ſupported on 19 pair of conical ſtone pillars at 52 feet aſunder, and the middle ones 125 feet in height! at Chirk is a very large ſtone aqueduct bridge of 10 arches, 200 yards in length and 65 feet high, over the Ceriog river; and over the Allen river there is alſo an aqueduct bridge. This canal is fed from the Dee river by the Llandinillo branch, and that river is compenſated by a cut from Bala-pool, and, all ſprings within 2 miles of this canal may be taken for its uſe. Near Ruabon, one of *Rowland and Co.*'s balance locks was, in 1797, tried on a 12 feet fall for ſaving water, as before mentioned. The engineers employed on this extenſive work, were Meſſrs. *William Jeſſop*, *Thomas Telford*, *— Fletcher*, and *Thomas Dadford*; the moſt conſiderable progreſs was firſt made at the northern end of the line, and in February 1796, flatts laden with coals began to arrive at Cheſter from the Lancaſhire collieries by the Wirral branch, and ſoon after convenient paſſage-boats were eſtabliſhed, for the regular conveyance of paſſengers towards Liverpool or back, at lower rates than is charged on *Bridgewater*'s canal, according to diſtance. In January 1797, the navigation was continued to Beeſton brook; and in the ſame year the ſouthern end of the line was opened from Shrewſbury to the Weſton-Lullingfield tunnel. The immenſe aqueduct at Pont-Cyſylty was in hand in 1804, and was more than half completed before the end of that year, as was alſo the ſtone aqueduct at Chirk. The company are authoriſed to raiſe 500,000l., the amount of ſhares being 100l., which it ſeems were, in 1802, at 20l. below par. The rates of tonnage are, for coals, culm, limeſtone, lime, and ſalt, $1\frac{1}{2}$d. per ton per mile; for free-ſtone, timber, ſlate, iron-ſtone, lead-ore, iron, and lead, 2d., and for all other goods 3d. per ton per mile, except road materials and manures (but not lime) upon the pounds, or when the water flows waſte over the lock-weirs. On croſſing the *Dee* river at Cheſter, goods pay 2d. per ton to the Dee company, and their tolls are guaranteed to the amount of 210l. annually. While this canal was projecting, a rival ſcheme was ſtarted, called the Eaſtern Grand Trunk from the *Severn* at Shrewſbury to the *Cheſter* canal at Crow's neſt, with cuts to Vable-Cruis, to Bonham-Furnace, Holt, and other places.

EREWASH CANAL. Act 17 Geo. III.—The general direction of this canal is nearly north for $11\frac{3}{4}$ miles along the ſkirt of the county of Derby, near to Nottinghamſhire; its northern end is conſiderably elevated above the level of the ſea; its chief object is the export of coals from the numerous collieries on its banks, and thoſe on the banks of the *Nutbrook* canal which joins it at Stanton, and the *Nottingham* canal which joins it near Langley Bridge; the branch of the *Derby* canal joins it between Sandiacre and Long Eaton, and the *Trent* canal near Sawley. It commences in the *Trent* river near Sawley (oppoſite nearly to the *Loughborough* navigation or Soar river,), and terminates in the *Cromford* canal at Langley Bridge, the riſe being $108\frac{2}{3}$ feet; there is an iron *rail-way* branch to Brinſley coal-works, on which an experiment was, as before related, made about the year 1800, on the load which one horſe could draw both up and down the declivity. By the act of 33 of Geo. III. for *Derby* canal, a reduction of the rates between the junction therewith and the *Trent* river was made, conditionally, that no other junction be made between this canal and Derby, but the preſent one near Sandiacre; and by the 34 of Geo. III. for *Trent* river, the annual rent of 5l. is commuted for a toll of 6d. on every laden boat which ſhall croſs the *Trent* between the

Soar river and this canal. A reſervoir belonging to the *Nottingham* canal has a gauge-ſluice, which furniſhes a regular and daily ſupply of water to this canal. The firſt ſurvey for this line of canal was made in the year 1776.

Eske River, (*Montroſe*). This river is navigable but a ſhort diſtance in the tide-way from the German Ocean to the town of Montroſe, in Angus county in Scotland. Montroſe is the 67th Britiſh town, with 7,974 inhabitants.

Eske River, (*Whitby*). The navigable part of this river is but ſhort, in a S.W. direction in the Eaſt Riding of Yorkſhire: it commences at the German Ocean, and extends to Whitby bridge. In 1765 Mr. *John Smeaton* was conſulted about clearing this river and the harbour of Whitby, of the ſhail or refuſe ore, from which alum had been manufactured, and whereby the harbour had become in time nearly choaked up. Whitby is the 75th Britiſh town, with a population of 7,483 perſons; within a few years paſt, a pier has been built with free ſtone, under the direction of Mr. *John Rennie*, for the improvement of the mouth of this harbour.

Exe River. The courſe of this river is nearly N.W. for about 10 miles in the county of Devon; its principal object ſeems the ſupply of Exeter and Topſham; near Topſham it is to be joined by the *Grand Weſtern* canal. It commences in the Engliſh Channel at Exmouth, and terminates at the city of Exeter, which is the 21ſt town in Britain, with 17,398 inhabitants: from Exeter it was in 1800 propoſed to continue the navigation to Crediton; and in 1769, the *Exeter and Uphill* canal was propoſed to be made from the ſame place.

*Exeter and Crediton.* In the year 1800 it was propoſed to make the rivers Exe and Credy navigable, from Exeter city to the town of Crediton, about ſeven miles, above Exeter quay on the river *Exe*.

*Exeter and Uphill.* In 1769 Mr. *John Brindley* ſurveyed the country for a canal from the river *Exe* at Exeter, by Tiverton, Wellington, Taunton, and Glaſtonbury, to the Britiſh Channel near Uphill; the objects of which have been ſince embraced in the *Grand Weſtern* canal.

Fergus Canal. This is one of the Iriſh inland navigations, in aid of which, public money was from time to time granted, though in the preſent inſtance we are told that it amounted to no more than 85l.

Forth River, (*or Firth*). This principal river of North Britain has its courſe nearly weſt for about 70 miles between the counties of Fife, Haddington, Edinburgh, Linlithgow, Stirling, Perth, and Clackmannan, the firſt 33 miles being a very wide eſtuary, the next 18 miles are ſtill of conſiderable width, and the laſt 13 miles next Stirling are remarkably crooked. An immenſe general trade is carried on upon this river, and for the ſupply of the metropolis of Scotland, aſſiſted by the *Edinburgh and Glaſgow* canal, that joins it at Leith, the *Burrowſtowneſs* at that town, the *Forth and Clyde*, or great canal at Grangemouth, the *Caron* river near Rothkennar, and the *Devon* river near Cambus Quay. Edinburgh (with Leith) is the 3d Britiſh town, with 82,560 inhabitants, Dumferline is the 52d, with 9,980 perſons, and North Berwick, Crail, Anſtruther, Dyſart, Kirkaldie, Kinghorn, Bruntiſland, Inverkeithing, Muſſelburgh, Queen's-Ferry, Burrowſtowneſs, Linlithgow, Falkirk, Culroſs, Clackmannan, Alloa, and Stirling, are alſo conſiderable towns on or near this fine river. It commences in the German Ocean, and terminates at Stirling bridge, and is navigable for ſhips through a great part of its courſe; at Cambus Quay the ſpring tides riſe 20 feet, but below this there are ſands called the Thraſk Shallows, concerning the removal of which, Mr. *John Smeaton* was conſulted in 1767. In 1801, the channel ſouth of Inch-keith iſle was deepened, to enable ſhips to approach Leith harbour ſafely and readily. Leith harbour has undergone great improvements of late years under the acts of the 28, 38, [illegible] and 45 of Geo. III., by the laſt 25,000l. of the public money was granted for the wet-docks and other works which have been carrying on there under Mr. *John Re*[illegible] ſince the laying of the foundations, 14 May 1801. Methil harbour on the north ſide of the *Forth* is alſo under improvement, and by the 45 of Geo. III., 2,000l. of the public money was granted towards the building of the pier there. In the year 1767, Meſſrs. *Watt* and *Moriſon* ſurveyed the upper part of the *Forth* river, and propoſed to extend a navigation from Sterling bridge to the ſlate and lime quarries in Aberfoil, on which the opinion of Mr. *John Smeaton* was alſo taken.

Forth and Clyde Canal. Acts 8, 13, and 24 of Geo. III. — The general direction of this great canal is nearly weſt for 35 miles, in the counties of Stirling, Dumbarton, and Lanerk, in Scotland: it croſſes a low part of the grand-ridge between the tide-ways of the eaſt and weſt ſeas; its principal object is a communication between thoſe important rivers, the *Forth* and the *Clyde*, and between the northern metropolis, and the great manufacturing towns of Glaſgow, Paiſley, &c.; near to Grangemouth the *Burrowſtowneſs* canal joins it. Glaſgow is the 5th Britiſh town, with a population of 77,385 perſons, and Falkirk the 59th, with 8,838 inhabitants. Kirkintulloch and Dumbarton are alſo conſiderable places near the line. This canal commences at Grangemouth harbour in the *Forth* river, and terminates at Bowlings bay near Dalmuir-Burnfoot, in the *Clyde* river. There is a cut of 2¾ miles to the town of Glaſgow, where it joins the *Clyde* river, the *Monkland* canal, and the *Edinburgh and Glaſgow* canal; and it was in 1803, propoſed to join the *Glaſgow and Saltcoats* canal; there is another cut with a lock into the *Caron* river at Caron-ſhore, near the great Caron iron-works. From low-water in the *Forth* in Grangemouth lock, N° 1, to lock N° 20, 10¼ miles, is a riſe of 165 feet; thence to lock N° 21, the ſummit-level is 16 miles, and thence to low water in the *Clyde* at Bowling's bay lock, N° 39, is a fall of 156 feet; the width of the canal is 56 feet at top, and 27 at bottom, and the depth of water 8 feet; each lock is 75 feet long, and 20 feet wide in the clear, and veſſels of 70 or 80 tons are uſed. This canal is croſſed in 33 places by draw-bridges, has 33 culverts or arches under it, and 10 large aqueduct bridges; that over the Kelvin is 400 feet in length, and 70 feet high above the ſurface of the river, (ſee *figs.* 19, 20, and 21, *Canals*, *Plate* II.) and there is a large aqueduct which croſſes the turnpike road from Glaſgow to Stirling at Kirkintulloch. At Kilmananmuir is a reſervoir of 70 acres extent, and 22 feet deep at the ſluice; and near Kilſyth is another of 50 acres, 24 feet deep for ſupplying the ſummit-level of this canal. In Bowlings-bay, and near the Kelvin aqueduct, are dry-docks, and other conveniences for repairing of veſſels and boats. Mr. *John Smeaton* was firſt employed to ſurvey this line in 1764, and he laid the preſent deſign, and executed a conſiderable part of the eaſtern end before 1775, when the work ſtood ſtill for ſome years, after which, Mr. *Robert Whitworth* was called in; he completed the remainder, and it was opened with great ſolemnity on the 28th of July 1790. The deſign of a canal between the *Forth* and *Clyde* has been at times entertained ever ſince the reign of Charles II., and beſides the above engineers, ſince the year 1723, Meſſrs. *Gordon*, *Mackell*, *Watt*, *Brindley*, *Golborne*, *Thomas Yeoman*, &c. have been conſulted or employed. The canal was firſt made to commence in the *Caron* river, about a mile from its mouth, but was afterwards continued into the *Forth* at Grangemouth harbour. The proprietors were authoriſed in their firſt act to raiſe 200,000l. in 100l. ſhares; after which, 50,000l. of the public money was granted to aid the work; in 1783, 212,000l. had been expended, and no dividend or intereſt had been paid on the ſhares. The rate of tonnage is 2d. per ton per mile on all kinds of goods, except lime and lime-ſtone, which is to pay $\frac{1}{2}$d., and iron and iron-ſtone 1d. per ton per mile, while road-materials (except lime-ſtone) and manures are to paſs toll free. For unloading or loading of Britiſh or Iriſh veſſels in Grangemouth harbour, 1d. per ton is to be paid, (by 24 Geo. III.) and for foreign veſſels 2d. per ton. Rafts of fir timber are allowed to be floated upon this canal and paſs the locks, theſe often contain 70 tons each. An accident is related of a veſſel coming down from the weſtward on this canal, when the wind blew ſtrong from that quarter, and not being ſtopped in time at one of the locks, ſhe bore down the gates, and went down ſuddenly into the pound below. In December 1801, a veſſel conſtructed by Mr. *Symington*, (as already deſcribed) was tried on this canal for dragging or towing boats, by the operation of a ſteam-engine; to the head of this veſſel ſtampers were applied, that could be worked by the engine for breaking ice, when the canal is frozen over.

**Foss-dyke Canal.** The general direction of this navigation is nearly S.E. for 11 miles, in the counties of Lincoln and Nottingham; it is upon one level, not much elevated above the ſea, though a great diſtance from it, and preſents the curious inſtance of a canal diſcharging its waſte water into one river (the *Witham,*) while flood-gates are neceſſary at the other end, to keep out the waters of the other river (the *Trent*); its object is a communication between theſe two rivers, for ſupplying coals and exporting farm produce. Lincoln is the 76th Britiſh town, with a population of 7,398 perſons. This canalcommences in the *Trent* river at Torkſey, and terminates in Brayford meer, a natural pool in the *Witham* river, near Lincoln. It has a lock at Torkſey, conſtructed on the principle of a ſea-lock, that is capable of penning the water into the canal, or out of it, according to the circumſtance whether the *Trent* or it may be the loweſt; between Brayford meer and Lincoln high-bridge, a hard of gravel or ſhallow, called Brayford head, held up the water in this canal, to about $2\frac{2}{3}$ feet deep, which otherwiſe would, in dry times, have been emptied into the Witham, too low for navigation. Mr. *John Smeaton* and Mr. *John Grundy* were conſulted in 1762, and the former engineer again in 1782, when he recommended raiſing the banks of this canal to obtain a better depth of water, cutting off its connection with the Witham by a pound-lock, and ſupplying it with water by an aqueduct or feeder, from a reſervoir to be made near the Witham, ſouth of Brayford meer. We are not acquainted with the date when this canal was firſt dug or made navigable; Mr. Elliſon's wharf thereon, near its eaſt end, was, it appears, built about 1742.

**Foss Navigation.** Acts 33 and 41 Geo. III.—The direction of the *Foſs* river, which this navigation follows, is nearly N. by a crooked courſe of about 13 miles, through the North Riding of Yorkſhire: its elevation is not very great above the level of the ſea; its objects are the ſupply of the city of York, the import of coals for the uſe of the adjacent country, and to effect a better drainage of the ſame. York is the 23d Britiſh town, with 16,145 inhabitants. This navigation commences in the *Ouſe* river at the city of York, and terminates at Stillington mill. It is fed by a reſervoir on Oulſtone moor: it appears that the corporation of York were by a licence of king *Richard* II. required to erect and maintain proper bridges over this river. This company were authoriſed to raiſe 45,400l. the amount of ſhares being 100l. each. The rates of tonnage will be found in *Phillips' 4to. Hiſtory, Appendix*, p. 81 and 82; and in the laſt act, by which an additional $1\frac{1}{2}$d. per ton, on heavy articles, were impoſed, and by which the proprietors were authoriſed to proceed no higher than Sheriff-Hutton bridge with their works, until the neceſſary funds were accumulated to proceed with the remainder of their line. Some years ago, a pleaſure-boat, made wholly of ſheet iron, was tried on this navigation, 12 feet long, and capable of carrying 15 perſons, and yet ſo light that two men could carry it.

**Glamorganshire Canal.** Acts 30 and 36 Geo. III.—The general direction of this canal is nearly N.W. for 25 miles, in the county of Glamorgan in South Wales. Its objects are the export of the produce of the immenſe iron, coal, and lime works in the neighbourhood of Merthyr Tidvil, &c. and the ſupply of the rapidly increaſing population thereof; at Eglwyſila the *Aberdare* canal joins, and the *Cardiff and Merthyr* rail-way runs by its ſide, and joins it at thoſe two places. Its northern end is conſiderably elevated. Cardiff and Caerphilly are conſiderable towns on or near the line; it commences in a ſea-baſon, or dock, in the *Severn*, at the Lowyer-layer near Cardiff, and terminates near the town of Merthyr; it has a *rail-way* branch from Merthyr to Dowlais iron works. From the tide-way at Lower-layer to Merthyr is a riſe of near 600 feet, and during a part of this diſtance the canal ſkirts precipitous mountains at the height of near 300 feet above the river Tav or Taaff, which it cloſely accompanies through its whole length. The floating dock at Lower-layer is 16 feet deep, in which a great number of ſhips, of 300 tons burthen, can lie conſtantly afloat, and load or unload, either at the ſpacious warehouſes on its banks, or from, or to, the boats belonging to this canal, or the trams uſed on the *Cardiff and Merthyr* rail-way, that here commences. There is a large aqueduct bridge over the Tav near Gallygare. This company were authoriſed to raiſe 100,000l. and to the powers for raiſing the laſt 10,000l. this ſingular condition was annexed, viz. that the whole concern ſhould be completed within two years, after which no further money ſhould be applied, except for repairs. At Merthyr there is a famous water-wheel, made of caſt-iron, 50 feet diameter, at Mr. Crawſhaw's works; the water being conveyed thereto for a great diſtance in an iron aqueduct.

*Glaſgow and Saltcoats.* In May 1803 the line of country between the *Clyde* river at Ardroſſan, near Saltcoats, and the *Clyde* river again at Glaſgow (paſſing Paiſley and connecting with the *Cart* river) was ſurveyed by Mr. *John Rennie;* in 1805, the ſubject was revived, and met the ſupport of the earl of Eglingtown and many others, coupled with the deſign of building a pier on a ledge of rocks near Caſtle Craigs, and forming wet-docks, &c. to be called Ardroſſan harbour, for which an application was made to parliament in the ſame year. At Glaſgow this canal would connect with the *Forth and Clyde*, the *Monkland*, and the *Edinburgh and Glaſgow:* the line thereof is through a country rich in coals and lime-ſtone.

**Glenkenns Canal.** Act 42 Geo. III.—The direction of this canal is firſt N.E. and then N.W. for about 27 miles, in Glenkenns, in the county of Kirkcudbright in Scotland: it is not very greatly elevated; the object of it is the export of the coals, iron-ſtone, lime, and other minerals with which the country abounds; Kirkcudbright and New Galloway are conſiderable towns near the line. It commences in the tide-way in the *Dee* river at Kirkcudbright, and terminates in the boat-pool at Dalry. There is proviſion made for branches to the neighbouring mines and rail-ways, and inclined planes may be ſubſtituted, inſtead of a canal and locks in any part. The company is authoriſed to raiſe

raiſe 45,000l. the ſhares being 100l. each, but it is provided, that the works are not to commence until 20,000l. is ſubſcribed, and that within five years, or the powers of the act are to ceaſe; water may be taken from within 2000 yards of the line, except certain ſtreams uſed for irrigation.

**Gloucester and Berkley Canal.** Acts 33, 37, and 45 Geo. III.—The general direction of this canal, one of the largeſt in England, is nearly N.E. for 18¼ miles, in the county of Glouceſter; it is but very little elevated above the ſea; its object is to ſhorten the navigation for ſhips by a ſerpentine courſe of 28 miles on the *Severn* river, between Berkley and Glouceſter; near Wheatenhurſt it croſſes and unites with the *Stroudwater* canal; Glouceſter is the 72d Britiſh town, with a population of 7,579 perſons; Berkley is alſo a conſiderable place. This canal commences with a ſea-lock in the *Severn* river at Berkley-pill, and terminates in a grand and capacious baſon, connecting with the *Severn* river at Glouceſter, it has a ſhort branch to a new wharf at Berkley town, and another of about 2 miles in length to the *Severn* river at Hock-crib in Arlingham; the whole is on one level with tide-locks at its connecting points with the *Severn* to preſerve its water at one conſtant height. This canal is 70 feet wide, and 15 or 18 feet deep in water, and the locks, &c. thereon, are capacious enough to admit ſhips of 300 tons burthen to paſs! The company are authoriſed to raiſed 200,000l. in 100l. ſhares. The tonnage varies on different ſized veſſels, and is too long for us to inſert, the particulars will be found in *Phillips' 4to. Hiſtory, Appendix*, p. 83 and 84. Unforeſeen difficulties have attended the execution of this wide and deep canal, by interſecting a hard rock for great diſtances in the level meadows, where no ſuch thing was expected. Some immenſely large ſlips have happened in the banks, and the walls of the Glouceſter baſon ſlipped in, notwithſtanding the land-ties which had been provided; the upper end of the canal, for ſeveral miles, has been finiſhed; in 1797, it was ſaid that only 6 miles remained to be cut; and we hope, that the act of laſt ſeſſions will be the means of ſpeedily completing the whole. Mr *Haſkew*'s machine, calculated to aſſiſt in excavating a canal, was here tried in 1796, as before mentioned.

*Glouceſterſhire Rail-way.* In the year 1804 it was propoſed to conſtruct a rail-way from the *Avon* river at Bitton below Bath to Sodbury coal-works in Glouceſterſhire, with branches to Pucklechurch, Haul-lane, Coal-pit-heath in Weſterleigh, Smith's tynings, and other collieries, in order to bring their produce to Bath and Briſtol, and for the conſumption of the interior of the country, by means of the *Kennet and Avon* canal.

**Grand Canal**, (*Ireland*). This canal was commenced, we believe, ſoon after the year 1753, but we have not the dates of the earlier acts; ſince the union there was one paſſed, the 43 Geo. III. The general direction of this canal is nearly weſt, for 61½ miles through Dublin, Kildare, and King's Counties, in Ireland; it paſſes a low part of the grand ridge of Ireland, on the Bog of Allen. Its objects are the ſupply of Dublin with coal, &c., the varied produce of the banks of the *Shannon*, and opening an inland communication through the country. It commences in a grand baſon in James-ſtreet, Dublin (which connects with the *Liffey* river and the new *Docks*), and terminates in the *Shannon* river, at Tarmonbury, near Moy's Town; it has collateral branches to the *Boyne* river at Edenderry, to the *Barrow* river at Moneſtraven, and alſo at Portarlington; there are alſo branches to Naaſtown and to Johnſtown. This canal is, we believe, 5 feet deep, the locks are 80 feet long and 16 wide, in the clear, and are built of hewn ſtone; it has employed the attention of various engineers, among whom are mentioned, Meſſrs. *Omes*, *Vallency*, *John Trait*, *William Jeſſop*, &c. In the year 1770 this canal had proceeded from Dublin into the Bog of Allen, when, owing to miſmanagement, it ſtood ſtill for ſeveral years, and it was not until the beginning of 1804 that the whole line was finiſhed and opened. The ſums of the public money which have been granted by the parliaments to aid this work are immenſe; between 1753 and 1771 they amounted to 78,231l. It has been propoſed to reduce the tolls or tonnage ſince the opening of this canal. In the beginning of the preſent year (1805) it was propoſed to continue a branch from this canal, near Athy, for 9 miles, to the foot of the Doonane Hills, in Queen's county, and thence to tunnel two miles into the hill, to drain the rich veins of coal therein, and bring out their produce.

**Grand Junction Canal.** Acts 33, 34, three of the 35, 36, 38, 41, 43, and two of the 45 Geo. III.—The general direction of this canal is nearly north-weſt for 90¼ miles, in the counties of Middleſex, Hertford, Buckingham, Bedford (a very ſmall diſtance), and Northampton. It has a ſummit of conſiderable height near Tring, which it paſſes without a tunnel; and near its northern end it croſſes the grand-ridge by a tunnel. Its principal objects are, a communication between the metropolis and the various canals of the midland counties, the ſupply of coals, deals, ſlate, &c. to the ſeveral towns on the line and branches, and the export of the agricultural products, lime, flints, &c. of the country through which it paſſes; at Northampton it joins the *Nen* river by a *rail-way* branch, and the ſame is intended there alſo to join the *Leiceſterſhire and Northamptonſhire Union* canal. London, as is well known, is the firſt town in Britain for population, with 864,845 inhabitants, and Northampton is the 85th, with 7,020 perſons; Brentford, Uxbridge, Rickmanſworth, Watford, St. Albans, Hemel-Hempſtead, Berkhampſtead, Tring, Wendover, Ayleſbury, Leighton-Buzard, Fenny-Stratford, Newport-Pagnel, Stoney-Stratford, Buckingham, Towceſter, and Daventry, are alſo conſiderable towns on or near this canal or its branches. The commencement of this canal is in the river *Thames*, near the extremity of the tideway at Brentford creek, and its termination in the *Oxford* canal at Braunſton. From Bull bridge a branch, 13½ miles in length, goes to Paddington, one of the environs of London; to the town of Rickmanſworth, there is a cut of about ¼ of a mile, with a lock at its entrance; from Bulbourn head a branch extends for 6¾ miles to Wendover; from Coſgrove a branch of 1¼ mile extends to Stoney or Old Stratford, and thence 9½ miles further to Buckingham; and from Gayton a *rail-way* branch of 5 miles extends to the river *Nen*, and the intended termination of the *Leiceſterſhire and Northamptonſhire Union* canal at Northampton. To Watford a branch of 2 miles, and thence about 8 miles farther to St. Albans, has been ſurveyed and provided for in the acts; another to Ayleſbury of about 6 miles, and another to Daventry of 1½ mile in length, but theſe laſt are not executed. From the *Thames* at Brentford to Two-waters is 28½ miles, with 268 feet riſe; thence to Cowroaſt is 7¼ miles, with a riſe of 127 feet; thence to the Wendover branch is 3¼ miles, of the higheſt ſummit-level; thence to the croſſing of the Ouſe river, between Wolverton and Coſgrove, is 25¼ miles, with a fall of 192 feet (this being the loweſt place); thence to Stoke Bruern is 6½ miles, with a riſe of 112 feet; thence (through the Bliſworth tunnel) to the ſouth end of Whitton pariſh, 13½ miles, is level; thence to Whitton mill, in Long Buckby, ¾th of a mile, is a riſe of 60 feet; thence along the ſummit-level, and through Braunſton tunnel to its north end, 4¼ miles, is level; and thence to the *Oxford* canal at Braunſton, near 1 mile, is a fall of 37 feet. The Paddington branch is level (at about 90 feet above the *Thames*, and 48½ feet above the Strand-pavement at Exeter-change).

change). The Wendover branch is level, and connects with the Bulborne or Tring ſummit pound: the Buckingham branch has a riſe of 15 feet; the Northampton branch has a fall of 120 feet, and the cut to Daventry is to have a riſe of 60 feet. The width of the main line is 36 feet at top, about 24 feet at bottom, and 4½ feet deep in water: the Wendover branch is 28 feet wide at top, 18 at bottom, and 4½ feet deep; and the Buckingham branch is only 20 feet wide at top, 10 at bottom, and 4½ feet deep in the general. The Northampton rail-way, which is now (October 1805) nearly or quite finiſhed and ready for opening, is of iron, and double, that is, has two roads for the carriages going different ways. The locks on the line are 86 feet long, 15 feet wide in the clear, and riſe about 7 feet each on the average, requiring about 9030 cubic feet, or 250 tons of water to fill them each time that a barge paſſes. On the line there are 101 locks, beſides the 9 ſpare ones in Wolverton-valley; on the Buckingham branch there are 2 locks. Two kinds of veſſels are in uſe upon this canal, barges with ſquare heads and ſterns, and flat bottoms, that carry 60 tons, and boats with ſharp ends, or nearly ſo, of half the width, that carry 25 tons. At White-friars, juſt above Black-friars-bridge, on the *Thames*, this company built extenſive warehouſes, over a dock, in which barges lay afloat from one tide to the next; theſe are now let to Mr. *Pickford*, the great waggon and boat-maſter. At Paddington a ſpacious baſon or ſtraight cut, 400 yards long and 30 wide, has been formed with wharfs at its head, and others are daily extending weſtward along its ſides; behind this, on the north ſide, is a ſpacious yard for a vegetable and a hay and ſtraw market, with immenſe ſheds, under which loads of thoſe articles can ſtand in the dry when it rains; and on the ſouth ſide pens are erected and proviſion made for a large cattle market. The number of wharfs erected on this extenſive line and its branches by individuals are too great for us to attempt to particularize them. The number of culverts or ſmall water-courſes under the canal and its branches are very great. And on the towing path there are a number of large and high wooden bridges for croſſing the entrances to branches, docks, or over ſtreams of water; for ſome diſtance from Paddington proviſion is made under the bridges for a towing path on each ſide of the canal. The tunnel between Stoke-Bruern and Bliſworth (already deſcribed), is 3080 yards in length, 15 feet wide, and 19 feet high, at 60 feet below the top of Bliſworth hill, through which it penetrates. Braunſton tunnel, between that place and Daventry, is 2045 yards in length: another tunnel was at firſt intended near King's-Langley for avoiding Caſhiobury, and other parks in the Colne valley; but an agreement was afterwards come to with their owners for a paſſage through them, inſtead of tunnelling. Between Cow-roaſt and Bulbourne there is an immenſe deep-cutting for paſſing the great range of chalk-hills near Tring; this extends for 3 miles, and is 30 feet deep in the higheſt part; near Dawley there is a great length of deep-cutting through the immenſe bed of gravel at that place; at the ends of the Bliſworth tunnel, and at ſeveral other places there are alſo deep-cuttings. Between Wolverton and Coſgrove a ſtupendous embankment, with three aqueduct arches under the ſame, has been conſtructed, ſince the locks were made for croſſing the Ouſe river, as above mentioned, over which the canal has, ſince Auguſt 1805, been conducted, aud by which 4 locks on the ſouth ſide of the valley, and 5 locks on its north ſide, are avoided, except a lock of 18 inches riſe, near the north end of the embankment, by which 12 miles in length of level pound is held up (on the line and Buckingham branch), and ſeparated from 10 miles of level pound ſouth thereof, to beyond Fenny-Stratford town, (where another lock of only 18 inches riſe occurs, to hold up a pound of ſome miles in length that was intended, but for a miſtake in the levelling, to have been in one pound); this embankment is ½ a mile long, and 30 feet high, where it croſſes the Ouſe. At Weedon-Beck, and at Bugbrook, there are alſo moſt ſtupendous embankments, and river and road aqueduct-arches, and many leſſer embankments and aqueduct bridges occur on the line and branches; thoſe over the Brent river, and over Bays-water on the Paddington branch are conſiderable. On Harefield Moor there is a very wide and large piece of water on the canal: others at Great Berkhampſtead, at Halton park, and two other places on the Wendover branch. Five conſiderable reſervoirs have been conſtructed for preſerving water for this canal, or the mills, whoſe ſtreams have been diverted for its uſe; that at Aldenham covers 68¼ acres, at Wilſtone is one of 40 acres, and thoſe at Weſton-Turville, Braunſton, and Daventry, are alſo of very conſiderable dimenſions. The principal feeder for the ſouthern ſummit is at Wendover, and there are others at Little Tring, Tring, and Miſwell (the laſt being arched over for ¼ of a mile). The middle and lower part of the line is ſupplied by a feeder at Soulbury, and the northern ſummit is ſupplied by a feeder from Watford, near Daventry; beſides which, that ſummit has had its banks raiſed to accumulate an extra depth of water in wet times, and a ſteam-engine has recently been erected for pumping up the water out of the level of the *Oxford* canal to that ſummit, that is let down therefrom by the lockage. At Little Tring an engine was, in June 1803, erected for pumping the water collected in Wilſtone reſervoir into the Wendover branch of the ſouthern ſummit-level; and at Naſh mill, ſome diſtance below Two-waters, in the Colne valley, an engine is now erecting to return the lockage water of 4 locks that are there placed near to each other. On the ſouth and north ſides of the Tring ſummit, ſeveral pairs of ſide ponds have been lately added to the locks, for ſaving part of their conſumption of water. Where the Towceſter river (the Tove) is croſſed and joined there are very conſiderable weirs or tumbling-bays, and others on the old courſe, in the Wolverton valley; and, between Great Berkhamſtead and Uxbridge, theſe are continually occurring, owing to the canal having unfortunately been conducted into and through almoſt every mill-dam in that diſtance: overfalls of leſs ſize are alſo very common on every part of the line, ſo are ſtop-gates, trunks, and every other neceſſary appendage and convenience to a navigable canal. Mr. *William Jeſſop* was the engineer to this extenſive concern; Mr. *James Barnes* and Mr. *John Holland* were employed in executing different parts of the works, on which Mr. *Thomas Telford* was lately employed to report his opinion; ſince 1803 Mr. *Benjamin Bevan* has been employed in repairing the leaky parts, conſtructing ſide-ponds, &c. in the middle diſtrict of this canal. The works on this canal commenced at both of its extremities, ſoon after the paſſing of the firſt act; and the tunnel at Braunſton being completed, the navigation was opened, in July 1796, as far ſouthward from the *Oxford* canal, as the great embankment at Weedon Beck; in June 1797, the ſame was extended to the next great embankment at Bugbrook; and about November in the ſame year, to the north end of the intended tunnel at Bliſworth. Beginning at the ſouthern end in the *Thames*, the navigation to Two-waters was completed in June 1798, and in June 1801 the branch therefrom to Paddington was opened; in the year 1799, the canal was completed to Bulbourne, and the branch therefrom to Wendover; in June 1800, it was extended to Fenny-Stratford; and about October 1800 to the ſouth end of the intended tunnel at Bliſworth; at the ſame time a double iron *rail-way* of near 3½ miles in length (ſince removed) was laid acroſs Bliſworth

Hill, to connect the two parts of the canal, and form the much wiſhed for grand junction; in May 1801, the branch to Buckingham was opened; it was not until March 1805 that the Bliſworth tunnel was completed, and the navigation of the whole line opened; and, laſtly, in Auguſt 1805, the immenſe Wolverton embankment was opened for improving the ſame, and avoiding 8 locks, but which locks ſtill remain by its ſide, as a reſerve, in caſe of accident, to this immenſe mound of earth, or the three large arches under it. This company were authoriſed by their firſt nine acts to raiſe 1,528,000l. to which their firſt act of laſt ſeſſion made a conſiderable addition; and it is feared that the expenditure will altogether exceed two millions ſterling! The ſhares are of 100l. value each, which have at ſome periods of the buſineſs ſold as high as 210l., and at others have been down at 65l.! Shares in this concern are allowed to be ſplit into ſuch ſmall portions among different holders, as ⅛th or 12½l. each. On the original ſhares no dividend or intereſt has yet been received, but now as the tolls amount to full 7,000l. per month, it is hoped a dividend will begin to be made. Inland coals from the rich and inexhauſtible mines with which this and other canals form direct communications, were forbid under ſevere penalties (although two legiſlative attempts to enforce the ſame proved ineſficient) to be brought nearer to London than the N.W. end of Grove park in Hertfordſhire, until the laſt act of the late ſeſſion mentioned above, by which 50,000 tons of ſuch coals are allowed to be brought to Paddington in the current year, on paying a duty equivalent to that paid in the *Thames* on ſea-brought coals. The market at Paddington, after an ineffectual and moſt extraordinary oppoſition from the city of London, was opened in May 1802, for the ſale of fat cattle, hay, ſtraw, corn, vegetables, &c. By the act 41 Geo. III., this company was authoriſed to lay pipes in certain ſtreets in Paddington, Mary-le-bone, &c. for ſupplying the inhabitants with water; but at that time, certain millers, whoſe dams the line had been made to paſs through, were not conſulted. In June 1801, packet-boats were eſtabliſhed, that continue to paſs regularly at ſtated hours during moſt of the year, for the conveyance of paſſengers and parcels between London and Uxbridge; and for ſome time after the opening of the Buckingham branch, a boat went regularly between Paddington and that town; but the number of paſſengers and parcels were found inadequate to ſupport the expence of ſuch an eſtabliſhment. Trading boats are not allowed to paſs along upon this canal except in the day time, unleſs ſuch as have a ſpecial licence from the company for ſuch purpoſe. Mr. *Pickford* has a great number of boats, which proceed as regularly day and night upon this canal, and the other canals north of it, as the mail-coaches do on the roads, although with leſs expedition. A common trading boat has been known to arrive at Paddington in 63 hours from Coventry. In December 1799, the experiment was firſt tried, of bringing fat Oxen to London in boats by means of this canal. The rates of *tonnage* on this canal were at firſt very low, as will be ſeen in *Phillips'* 4to. *Hiſtory*, *Appendix*, p. 91. Additional tolls were provided in the 43d of Geo. III. for paſſing the Bliſworth tunnel and Woolverton embankment; and by the firſt act of the laſt ſeſſions (45 Geo. III.), the rates on the whole line and branches were varied, and increaſed for ſhort diſtances. The act of the 33d provided certain rates, which are to be paid to the *Oxford* company (See *Phillips' Appendix*, p. 93.) for goods paſſing thereon to or from this canal, and this company is bound (ſince the beginning of 1804), to make up the ſame to the amount of 10,000l. per annum. This company is alſo bound to pay annually to the city of London the ſum of 600l. for the liberty of making a junction with the *Thames*; and all goods paſſing into or out of the ſame on this canal are to pay ½d. per ton, to be applied towards improving the middle navigation of the *Thames* river. The intended cut to Ayleſbury was, on account of the ſcarcity of water at Marſworth, where it was to join the line, changed for a rail-way, and in the year 1803, the ſame was begun; the iron rails were actually purchaſed, and brought to the ſpot, but, alas! in one of thoſe reverſes of favour to which borough towns are ever liable, the work was ſtopped, the rails were ordered to be ſold, and years may now perhaps elapſe before Ayleſbury is permitted to enjoy the advantage of a canal or rail-way communication. About the year 1793, an extenſion of the Rickmanſworth branch of this canal was propoſed to the town of Cheſham. In 1793, and again in 1802, it was propoſed to extend a branch from near Slapton to the foot of Puddle-hill between Dunſtable and Hockliff; one object of which was the export of the valuable white freeſtone from the quarries at Tottenhoe; this object may, however, it is preſumed, be obtained without ſuch cut; and ſtone of equal quality be got in ſeveral places on the ſummit branch. In the year 1802, the country weſtward of Uxbridge was ſurveyed by Mr. *John Holland*, with the intention of extending a branch of this canal from below Cowley lock, (continuing the level of the Paddington water) to the *Thames* at Harleford in Great Marlow pariſh; it was alſo propoſed, after croſſing and uniting with the *Thames* at this place, to extend this branch, by a riſe of three locks, to a ſide-cut of the *Kennet* river at St. Giles's in Reading, with a branch therefrom to the *Thames* at Sunning: the objects of this branch were, a more direct communication with the Briſtol channel, by means of the *Kennet and Avon* canal, the ſupply of the country bordering on this canal and its branches with peat manure from near Reading, the better ſupply of, and communication with London, by means of a canal without a lock, between the *Thames* at Great-Marlow, and Paddington, the gaining from the *Thames* that ſupply of water, which had been denied from the Colne for the intended water-works, and the lockage of the *London* canal; which was, in 1802, propoſed to extend from the baſon of this canal at Paddington to the *London Docks*, and thereby to communicate with the *Thames*; after which a *rail-way* was, in the ſame year, propoſed to extend from Paddington over nearly the ſame ground. It was before 1773 that a canal was firſt propoſed from Paddington to Uxbridge, nearly in the route of the line now accompliſhed; and in 1773, Mr. *James Sharp* propoſed an extenſion of this to the *Kennet* river. In June 1803, a ſurvey was taken for extending the intended Ayleſbury branch by Tame to the *Thames and Iſis* navigation, and *Wilts and Berks* canal near Abingdon. And in the ſame year, the *Leiceſterſhire and Northamptonſhire Union* canal was propoſed to be joined to the line of this canal at Long-Buckby wharf near Daventry, inſtead of joining its Northampton branch at that town.

Grand Surry canal. Act 41 Geo. III.—The general direction of this canal is nearly S.W. for about 12 miles, by a crooked courſe in the county of Surry, and through a ſmall part of Kent. It is not greatly elevated in any part: its objects are the ſupply of the neighbourhood through which it paſſes with coals, deals, manures, &c. the bringing of vegetables, and other articles for the ſupply of London: forming a communication between three points of the *Thames* river, and with the *Croydon* canal, which it joins near Deptford. It commences in the river *Thames* at Wilkinſon's gun-wharf in Rotherhithe, and is to terminate at the town of Mitcham; near Walworth a branch of about ¾ of a mile goes off to join the *Thames* at

Vauxhall creek by Cumberland gardens. There is to be a cut of near 1½ mile to Horſemonger lane; another of ½ a mile to Peckham; another of one mile to But-lane Deptford; another of ¼ of a mile to his majeſty's victualling office and the dock-yard at Deptford, and another of ⅓ of a mile into Greenland dock, by which it will again communicate with the *Thames* river.

From the river *Thames* to the junction of the *Croydon* canal the diſtance is 2 miles, and nearly level wich high water in the tide-way of the *Thames*, at which height the water is to be held up by tide or entrance locks; thence to the Vauxhall branch at Kennington common it is 3 miles and level; thence to Brixton-cauſeway, 1¾ mile, it has a conſiderable riſe; thence to the propoſed Kingſton branch, 4½ miles, it is level; and thence to Mitcham town it is ¾ of a mile: the Vauxhall, Horſemonger-lane, Peckham, But-lane, King's yard, and Greenland-dock branches, are all level. This canal is calculated for wide or river boats: near the commencement, at Wilkinſon's wharf, a large baſon is deſigned, and a ſmaller one at But-lane near the Greenwich road: acroſs Ruſhey-green to Brixton-cauſeway an inclined plane is intended. Mr. *Ralph Dodd* was, we are told, the contriver of this canal, and under his directions the works were begun, and conſiderable progreſs made between Rotherhithe and the Peckham branch; but for more than two years paſt, little further progreſs appears to have been made. The company were authoriſed to raiſe 60,000l. in 100l. ſhares. The tonnage on this canal varies from 2d. to 6d. per ton per mile on different kinds of goods. The company are to pay a rent of 60l. per annum to the city of London for communicating with the *Thames* river. Collateral cuts to the extent of 1500 yards may be made by conſent of the land owners. In 1800, it was intended to extend this canal 6½ miles further to the *Thames* river on the ſouth ſide of the town of Kingſton, which was to paſs the *Surry iron rail-way* at Merton abbey, by an aqueduct bridge 11 feet high in the clear, and the Wandle river by another 15 feet above its ſurface; from Norbiton common this was intended to branch again to the town of Epſom, 5½ miles, and from Mitcham the canal was there alſo propoſed to be extended to the town of Croydon. In the ſame year there was alſo a propoſal for extending the intended Kingſton branch to the *Wey* river (near the commencement of the *Baſingſtoke* canal), as part of one of the lines between *Portſmouth and London*. The *Croydon* canal company are to have a dock or baſon for their boats by the ſide of this canal near the *Thames* at Rotherhithe; which, with the entrance lock and baſon of this canal, are now excavating, and ſeem on a ſcale calculated for ſmall ſhips.

GRAND WESTERN CANAL. Act 36 Geo. III.—The general direction of this canal is nearly N.E. for about 35 miles, in the counties of Devon and Somerſet: it croſſes the ſouth-weſtern branch of the grand-ridge; its objects being a connection between the ſouthern coaſt and the Briſtol channel, the ſupply of the country with coals, deals, &c. and the export of farming produce. Exeter is the 21ſt Britiſh town, with a population of 17,398 perſons; Willington is the 73d, with 7,531 perſons; Tiverton the 94th, with 6,505 perſons, and Taunton, the 106th, with 5,794 perſons; Topſham, Bradninch, and Cullumpton, are alſo conſiderable towns near this line; which commences in the tide-way of the river *Exe* at the town of Topſham, and terminates in the *Tone* river at Taunton bridge; it has a cut of about ſeven miles to Tiverton, and other ſhort ones to Cullumton and Wallington. It is provided, that the brick bridges ſhall not have a riſe of more than 2½ inches in a yard on the aſcent of the road over them. Two reſervoirs are to be made in the valley of the Culm river, and two in the river Tone valley. Springs within 2000 yards of the line may be taken, and cuts to any place within five miles may be made by conſent of the land owners. The company are authoriſed to raiſe 330,000l., the amount of ſhares being 100l. each. We have not been able to learn that any progreſs is yet made in the cutting of this canal, although one through this line of country has been ſo long deſired, as appears by Mr. *Brindley*'s ſurvey for the *Exeter and Uphill* canal, that was propoſed in the year 1769.

GRANTHAM CANAL. Acts 33 and 39 of Geo. III.—The general direction of this canal is nearly eaſt, by a crooked courſe of 33¼ miles, in the counties of Nottingham, Leiceſter, and Lincoln: its eaſtern end is rather elevated. Its objects are the ſupply of Grantham and the neighbourhood through its courſe with coals, lime, deals, &c. and the export of farming products. Nottingham is the 17th Britiſh town, with 28,861 inhabitants; and Grantham the 85th, with 7,014 perſons; Birmingham is alſo a conſiderable town. This canal commences in the *Trent* river, near Holme-pierpoint, (almoſt oppoſite the *Nottingham* canal, to the *Trent* canal, and to the town of Nottingham,) and terminates at the town of Grantham; there is a branch of three miles in length to the town of Bingham. From the *Trent* river to Cropwell-biſhop, 6½ miles, is a riſe of 82 feet; thence to Stainwith-cloſes, 20 miles, is level; thence to Woolſthorpe point, 1¾ mile, is a riſe of 58½ feet; and thence to Grantham, five miles, is level: the cut to Bingham is level. This canal, which is through a clayey diſtrict, is wholly ſupplied by reſervoirs, of which, one at Denton is 20 acres, and nine feet deep, for ſupplying the head-level; and that at Knipton for receiving the flood waters of the Devon river, was 60 acres, and nine feet deep, and in 1804, the bank or head of this laſt was raiſed four feet higher. The company were authoriſed to raiſe 124,000l., the old ſhares being 100l. value each, and the new ſhares (200 in number) 120l. each. The tonnage on all goods paſſing to or from this canal and the *Trent* river is to be 2½d. per ton, and 1½d. per ton per mile for navigating on this canal: manures and road materials to paſs toll free, except lime-ſtone, which is to pay ¾d. per ton per mile. The *Newark and Bottesford* canal was at this time (1793) in contemplation to join this near Stainwith; and the tolls for entrance therefrom, or on goods paſſing into that intended canal, were ſettled in the firſt act above. The profits to the proprietors of this canal are limited to a dividend of 8 per cent. per annum, and after 3,000ls. are collected and depoſited as a fund, the above tolls are to be lowered, as much as circumſtances will admit. The *Trent* river proprietors are to take certain tolls on goods paſſing into or out of this canal to the *Nottingham* canal, in conſequence of their deepening the river near the entrances to theſe canals; and goods paſſing from this canal on the *Trent* are not to be liable to their new rates of 34 Geo. III. unleſs they paſs on the *Trent* canal, to be made under that act above Nottingham.

GRESLEY'S CANAL. Act 15 Geo. III.—The direction of this canal is about N.W., and level, in the county of Stafford: it is ſituate very near to the grand-ridge on its eaſtern ſide. Its objects are the ſupply of the town of Newcaſtle under-line with coals from Apdale collieries, and the export of coals from the mines to the weſt of it, by means of the *Newcaſtle under-line Junction* canal, which now joins it at each of its ends. This canal was conſtructed at the ſole expence of ſir Nigel *Griſley*, bart., who was bound by the act, for 21 years after 1775, to ſupply the inhabitants of Newcaſtle with coals at 5s. 6d. per ton of 2,400lb. or 3½d. by the ſingle cwt. (of 120lb.); and during the following term of 21 years, their price was not to exceed 6s. per great ton. In 1796, the *Commercial* canal was propoſed to connect with this canal at each end, as the *Newcaſtle under-line Junction* afterwards did in 1798.

Grimsby Canal. Act 36 Geo. III.—This canal has a S.W. direction for $1\frac{1}{2}$ mile, in Lincolnſhire: it is one of the largeſt cuts in England, and calculated to admit ſhips of 700 to 1000 tons burthen. It commences in the tide-way in the *Humber* river near its mouth, and terminates in the ſpacious wet-dock in Grimſby harbour. The lock to this canal is 126 feet long, 36 feet wide, and the walls are 27 feet high; the coſt of it, we are told, was 14,000l. beſides the piling for the foundation, although bricks were delivered there at 18s. 6d. per thouſand, and ſtone at 8d. per cubic foot. The depth of water in this canal is 20 feet: it was conſtructed under the direction of that able engineer Mr. *John Rennie*. In the year 1804, three acres more ſurface was excavated in addition to Grimſby wet-docks, and the ſame was re-opened, after a temporary interruption, on the 24th of July.

Hamoaze River. This river, or rather eſtuary, has nearly a north courſe for about nine miles, between the counties of Cornwall and Devon on their ſouthern coaſt: it is frequented by the largeſt ſhips of the royal navy. Plymouth is the 9th Britiſh town, with a population of 43,194 perſons; Plympton-Earle and Saltaſh are alſo conſiderable towns near this eſtuary, which commences in Plymouth ſound near Cawſand bay, and terminates in the river *Tamar* near St. Mellion. Near Warley the *Tavy* river falls into it; and Cat-water, Sutton-pool, and Stone-houſe creek, are branches from this eſtuary. In 1767, Mr. *John Smeaton* was conſulted about a new bridge and cauſeway over Stone-houſe creek. In 1801, it was in contemplation to build a pier from Pinlee point for the better ſecurity of ſhips lying in Cawſand bay from the E.S.E. winds. By an act of 45 of Geo. III. 4,000l. of the public money was voted towards cleanſing and deepening Cat-water and Sutton-pool; and it is now in contemplation to conſtruct a floating-dock in Sutton-pool capable of holding 100 merchants' ſhips always afloat.

*Hampton Gay and Iſleworth Canal.* In the year 1792, a canal was propoſed, to take a courſe nearly N.W. for about 60 miles, in the counties of Middleſex, Buckingham, and Oxford; commencing in the *Thames* river at Iſleworth, and terminating in the *Oxford* canal at Hampton-Gay. It was intended to effect that junction between the metropolis and the midland canals, which the *Grand-Junction* now accompliſhes: it was to paſs the chalk hills by a tunnel at Wendover, and to have a cut of three miles to Ayleſbury.

Hartlepool Canal. This is only a very ſhort cut of 300 yards in length, on the coaſt of Durham, from the ſea into Hartlepool harbour: it was cut in the year 1764, at the expence of ſir John H. *Duval*, through a ſolid rock, to the great depth of 19 feet. In 1796, Mr. *Ralph Dodd* propoſed, we are told, ſome improvements of this harbour.

Haslingden Canal. Act 33 of Geo. III.—The general direction of this canal is nearly north for 13 miles, in the county of Lancaſter; it is conſiderably elevated, croſſing the Haſlingden and Liverpool branch of the grand-ridge. Its objects are the export of the rich ſtores of coal, limeſtone, &c. on its courſe, and a communication between Mancheſter and the *Leeds and Liverpool* canal. Bury is the 84th Britiſh town, with a population of 7,072 perſons; Haſlingden is alſo a conſiderable town. It commences in the *Mancheſter Boulton and Bury* canal at Bury, and terminates in the *Leeds and Liverpool* canal at Church. No locks are to be built on this line, except by conſent of three-fourths of all the millers who occupy the ſtreams of water; it is intended to erect inclined planes. The company are authoriſed to raiſe 87,600l.; the amount of a ſhare is 100l. The tonnage upon all kinds of goods which do not paſs a lock or inclined plane, $1\frac{1}{2}$d. per ton per mile; coals, or other mineral products, are to pay 2d., and timber, goods, wares, &c. 3d. per ton per mile, if they paſs any lock or plane. Road materials (except for turnpike roads), and all manures, except lime, are to paſs free on the levels, and through the locks when water runs waſte over their weirs. Paſſage-boats are to be ſpecially licenſed by the company inſtead of paying tonnage. No wharfage is to be charged at the public wharfs, unleſs on goods remaining there above three weeks. We do not underſtand that much progreſs is made towards the completion of this canal.

*Headon and Paul Canal.* It is now (1805) in contemplation to form a canal from the *Humber* river at Paul to the town of Headon in Holderneſs, about three miles in the eaſt riding of Yorkſhire: its objects are the ſupply of Headon with coals and other articles, and the export of agricultural products.

Hereford and Gloucester Canal. Acts 31 and 33 of Geo. III.—The general direction of this canal is nearly N.W. for $35\frac{1}{2}$ miles, in the counties of Glouceſter and Hereford; the middle part of this canal is conſiderably elevated. Its object is the export of coals from the neighbourhood of Newent, and of the cyder and agricultural products of the country. Glouceſter is the 72d Britiſh town, with a population of 7,579 perſons; and Hereford, the 89th, with 6,828 inhabitants. Newent and Ledbury are alſo conſiderable towns on this line. It commences in the tide-way of the *Severn* river at Glouceſter, croſſes Alney Iſle, and another branch of the *Severn* to Laſſington, and terminates near the *Wye* river at Byſters-gate in Hereford; it has a ſhort cut to Newent. From the *Severn* to Ledbury the diſtance is 18 miles, with a riſe of $195\frac{1}{2}$ feet; thence to Monkhide is $8\frac{1}{2}$ miles on the ſummit-level; thence to Withington marſh it is three miles, with a fall of 30 feet; and thence to Hereford, ſix miles, it is level. Newent cut is level. On this line are three conſiderable tunnels, that at Oxenhal is 2192 yards in length; at Cannon-Frome is one of 1320 yards; and near Hereford, another of 440 yards in length. Mr. *Joſeph Clowes* is the engineer; in July 1796, this canal was finiſhed, from the *Severn* to Newent, and in March 1798, the Oxenhall tunnel was finiſhed, and the navigation extended to Ledbury, and coals were in conſequence reduced in price at that town from 24s. to 13s. 6d. per ton! The company were authoriſed to raiſe 55,000l. The prices of work in 1794, on this canal, 4d. per cubic yard for ſtages of 20 to 25 yards of wheeling: wheel-barrows were not uſed for moving ſtuff to greater diſtances than 100 yards; puddling coſt 6d. per cubic yard. The rates of tonnage are for coals 2d. per ton per mile; for manures, bricks, and rubble ſtone, lime or clay, 1d. per ton per mile; corn, meal, hewn ſtone, hops, wool, and other goods, 3d.: there are alſo particular rates for certain parts of the canal. The cut acroſs Alney Iſle, owing to the tide of the *Severn*, entering it from each end, and dropping its ſediment in the middle, is very liable to choak with mud. Springs or ſtreams of water within 3,000 yards of the line may be taken for the uſe of this canal.

*Hereford and Lydbrook.* In 1802, it was propoſed to conſtruct a *rail-way* from the *Wye* river near the bridge in Hereford to join the ſame river again oppoſite to Lydbrook.

**Heyl River**, (or *Hale.*) The courſe of this river or rather eſtuary is nearly ſouth for two miles, in the county of Cornwall, on its north-eaſtern coaſt: it commences in *St. Ives* bay, and terminates at the town of St. Erth: it is navigable only for ſmall veſſels, being almoſt choaked at the entrance of the bay. In 1766, Mr. *John Smeaton* was conſulted on the building of a north-eaſt pier at the entrance of St. Ives bay; the ſpring-tides here riſe 26 feet.

**Horncastle Navigation.** Acts 32 and 40 of Geo. III.—The general direction of this navigation is nearly N.E. for about 11 miles, in the county of Lincoln; it is not much elevated above the ſea: its objects are the ſupply of Horncaſtle and its neighbourhood with coals, deals, &c. and the export of agricultural products. Horncaſtle and Tatterſhall are conſiderable towns on this line. It commences in the old *Witham* river near Tatterſhall, and occupies the ſite of Dyſon's and Gibſon's former cut to Tatterſhall, paſſing that town to Horncaſtle by the courſe of the Bain river. The company were authoriſed to raiſe 45,000l., the amount of each ſhare being 50l. The dividends are not to exceed 8 per cent.; but after 1000l. is accumulated as a fund for contingencies, the tolls are to be lowered, to keep the profits within that limit. The firſt rates of tonnage are given in *Phillips's* 4to. *Hiſtory, Appendix*, p. 24, but theſe were varied and increaſed by the laſt act above. This company purchaſed the old Tatterſhall canal, and were, by their firſt act, to contribute jointly with the *Witham* and *Sleaford* companies in the expences, during the next ſeven years, in improving and deepening the courſe of the *Witham* between Lincoln high-bridge and the *Foſſe-dyke* canal, in order to facilitate the paſſage of goods to and from the *Trent* river, and in conſequence, but half the accuſtomed *Witham* dues were to be paid for goods paſſing to and from this navigation. In September 1802, this navigation, and the baſon at Horncaſtle, were completed and opened.

**Huddersfield Canal.** Acts 33 and 40 of Geo. III. The general direction of this canal is ſouth-weſt for 19½ miles in Yorkſhire and Lancaſhire; it croſſes the Grand-Ridge, at a great elevation, by one of the longeſt tunnels in this kingdom, in a rocky mountain: its objects are the carrying of coals that are found towards both its extremities, the ſupply of part of the country with lime, the conveyance of farming produce to the great towns, and the forming of a more direct communication between Hull and Mancheſter and Liverpool. Huddersfield is the 81ſt Britiſh town, with a population of 7268 perſons: Aſhton-under-line is alſo a conſiderable town. This canal commences in Sir John *Ramſden's* canal near Huddersfield, and terminates in the *Mancheſter Aſhton and Oldham* canal, at Duckenfield Bridge, near the town of Aſhton-under-line (near which the *Peak-Foreſt* canal alſo joins it). From *Ramſden's* canal to Marſden the diſtance is 7¼ miles, with a riſe of 436 feet; thence and through the tunnel to near Saddleworth it is 4 miles, and level; and thence to the *Mancheſter Aſhton and Oldham* canal, 8¼ miles, is a fall of 334 feet. The lock at the entrance from *Ramſden's* canal is 8 feet wide, this canal being only intended for narrow and long boats. The Tunnel through the Stannage Hills near Marſden is to be three miles in length, near to which, on the ſummit-level, the company are authoriſed to make reſervoirs to contain 20,000 lock-falls of water, (each 180 cubic yards), and may make others if theſe prove inſufficient. About the year 1798, that part of the line between Huddersfield and Marſden was completed and opened; in the ſame year the head of a large reſervoir near Marſden broke, and the torrent of water let down thereby did conſiderable damage to the country below it. The company are authoriſed to raiſe 274,000l., the amount of ſhares being 100l. Theſe became greatly depreciated in value, about the year 1800, owing principally, it is ſuppoſed, to many of the original ſubſcribers not being able to anſwer the calls for money, by which the works were retarded, and the canal remained in an unproductive ſtate: the Tunnel under the Stannage Hill is now proceeding. The rates of tonnage are from ½d. to 3d. per ton per mile for different goods, (ſee *Phillips*'s 4to. *Hiſtory, Appendix*, pp. 135, 136.) beſides which 1s. 6d. per ton is to be paid extra, on all goods which paſs through the tunnel; leſs lading than 15 tons is not to paſs any lock, unleſs the water runs waſte thereat, without conſent; no rates are to be taken by Sir John *Ramſden* for the goods which paſs between his warehouſes at Huddersfield and this canal, this company to amend and keep that part of his canal in repair, in conſequence, and are to guarantee his tolls not being leſſened, taking an average of three years before this canal is cut. This company is alſo bound not to make any branch or extenſion of the canal to any other navigation to the eaſtward; but, in ſuch caſe, the tolls thereof are to be divided between *Ramſden's*, the *Calder and Hebble*, and *Ayre and Calder* proprietors, inſtead of being taken by this company.

**Hull River.** The courſe of this river is nearly north for about 12 miles, in the Eaſt Riding of Yorkſhire; it is but very little higher than the ſea; its objects are the ſupply of Beverley and the adjacent country with coals, deals, &c. and the ſupply of Beverley and Hull with farm produce. Kingſton-upon-Hull (or Hull) is the 16th Britiſh town, with 29,516 inhabitants; and Beverley is the 100th, with 6001 perſons. This navigation commences in the tide-way of the *Humber* at Hull, and terminates in the *Driffield* navigation upon the ſame river at Aike-beck mouth. In Leven pariſh (between Eſke and Leven-bars) this is joined by the *Hull and Leven* canal.

**Hull and Leven Canal.** Acts 41 and 45 of Geo. III. The courſe of this canal is nearly eaſt for about three miles, in the Eaſt Riding of Yorkſhire; it is in a very low ſituation; its objects are the ſupply of Leven town, of lime to the country eaſt of it, and the export of the agricultural produce thereof for the ſupply of Hull and Beverley. It commences in the *Hull* river, and terminates at Leven bridge. Mrs. *Charlotte Bethel* is the ſole proprietor of this canal, on which Mr. *John Rennie*, Mr. *William Jeſſop*, and Mr. *James Creaſſy* were conſulted. This canal was finiſhed ſome time ago; and the act of laſt ſeſſion was for raiſing the tolls, which were found diſproportionate to the expence of its conſtruction and management.

**Humber River.** Act 23 Henry VIII.—This noble river, or rather eſtuary, has nearly a weſt direction for about 40 miles between the counties of York and Lincoln. The tide flows with great rapidity through its whole length, and the depth of water is ſufficient for ſhips of conſiderable burthen, which trade in vaſt numbers to the port of Hull, and with the numerous eaſtern rivers which connect with it. Hull contains, as above ſtated, 29,516 inhabitants; and Barton is the 96th Britiſh town, with 6197 perſons. Grimſby, Pattrington, Headon, and Burton are alſo conſiderable towns on or near to this river. It commences in the German Ocean at the Spurn Head, and terminates in the *Ouſe* and the *Trent* rivers, at their junction at Trent-fall: it is joined at its mouth, near Tetney, by the *Louth* river; at Grimſby, by the Grimſby canal and docks; at Kingſton-upon-Hull, by the ſpacious Hull docks and by the *Hull* river; in Wintringham, by the *Ancholme* river; and at Foſs-dyke Clough, near Flaxfleet, by the *Market-Weighton* canal. The port of Hull, and the accommodations of this river, have been greatly improved, by the conſtructing of wet-docks at Hull; the acts 14, 42, and 45 of Geo. III. having paſſed for theſe purpoſes, the firſt dock was opened in September 1778. In 1800, the new Humber-dock was propoſed, from Myton-gates to Heſſel-gates, on the ſite of the old ramparts, to form ſeven acres of water, to which a 50 gun ſhip may have acceſs from the *Humber*, and 70 ſail of ſhips may lie conſtantly afloat, to be ſurrounded in part by ſpacious warehouſes. By the act for the ſame, 30,000l., in 100l. ſhares, was to be raiſed: theſe ſhares have ſince borne a premium of near 50 per cent. The act of the late ſeſſion was for raiſing more money to complete this vaſt undertaking, now in great forwardneſs. In September 1802, a ſmall dock was begun on the ſhore of the *Humber* for market and ferry boats; a number of dolphins or floating buoys were, about the ſame time, placed on the banks of the river. In 1774, Mr. *John Smeaton* was employed to build two light-houſes on the Spurn Head, at 300 yards apart, which, in June 1776, were in imminent danger of having their foundations undermined by a great ſtorm: in September 1803, the loweſt of theſe light-houſes was burnt down by accident. Coal-ſhips, paſſing the *Humber*'s mouth for the London market, pay 1d. on each chaldron of their cargo, towards the ſupport of theſe lights. In 1800 it was in contemplation to erect a light-houſe at Stallingborough, on the ſouth ſhore of the *Humber*. In 1802 the *Cottingham and Hull* canal was propoſed, to connect with this river at Hull; in the ſame year, the *Keyingham-Level* navigation was propoſed to join at Stone-creek. In 1805 the *Headon and Paul* canal was propoſed to connect with it at Paul.

Idle River. The courſe of this river is nearly weſt for about 10 miles, in Nottinghamſhire: it commences in the *Trent* river at Stockwith, (near to the termination of the *Cheſterfield* canal,) and terminates at the town of Bawtry. At half a mile from the *Trent* is Miſterton ſas or ſluice, with an opening of 17⅔ feet, and two lock-doors 16 feet high, opening towards the *Trent*, to keep the floods thereof out of the low lands through which this river paſſes. In 1764, Mr. *John Smeaton* was conſulted on this navigation and drainage.

Inverness and Fort-William Canal. Acts 43, 44, and 45 of Geo. III.—This grand or *Caledonian* canal, as it is ſometimes called, has nearly a ſouth-weſt direction for 59 miles, in Inverneſs and Argyle ſhires, in the Highlands of Scotland; it paſſes the Grand-Ridge, through a low part thereof, interſected by deep lakes or lochs: its object is a connection between the Eaſt and Weſt Seas, by Linnke Loch and Murray Firth, for large ſhips drawing near 20 feet of water, and for avoiding the northern voyage by the Orkneys, or through *Pentland Firth*. Inverneſs is the 63d Britiſh town, with a population of 8732 perſons. Nairn, Cromarty, and Fort-George are alſo conſiderable towns on this line. It commences in the tide-way in Loch *Beauly* at Clachnacarry baſon, and, after paſſing through two large and two ſmall inland lakes, it terminates in the tide-way in Loch *Eil* at Corpach baſon. From the ſea-lock at Clachnacarry to the 2d lock, about ¾ of a mile, it is level, with high water in Loch *Beauly*, and nearly parallel thereto; thence for one mile to the 6th lock is a riſe of 45 feet by 5 locks; thence through Lochs Doughfour and Neſs to Fort Auguſtus is 28 miles, and level; thence to the eaſt end of Loch Oich at the 13th lock, 5½ miles, is a riſe of 53 feet by 7 locks; thence through Loch Oich, and the deep-cutting on the grand ridge weſt of it, is 54 miles and level; at the end of which the lock N° 12, at the eaſt end of Loch Lochy, makes a fall of 19 feet; thence through Loch Lochy to near Tor Caſtle is 16¼ miles, and level; and thence to the ſea-lock at Corpach, 2¼ miles, is a fall of 70 feet by 10 locks: in all 23 locks, beſides the ſea or entrance locks. This canal is 110 feet wide at top, 50 at bottom, and 20 feet deep; the locks are 152 feet long and 38 feet wide. At Clachnacarry and at Corpach are baſons, each 400 yards long and 70 yards wide. Twenty-two miles of this navigation is through a ſurpriſing freſh-water lake, called Loch Neſs, of ¾ to 1¼ mile in breadth, the middle part being 120 fathoms in depth! and its bottom muddy: this loch and the next never freeze, and it is ſaid that the waters thereof do not corrode iron. Loch Lochy is another large lake, 10½ miles in length, and from ¾ to 1¼ mile in width, and its greateſt depth 76 fathoms, through which this navigation paſſes: it has a ſecure little harbour, 200 fathoms long and 150 fathoms wide, at its eaſtern end. Another ſmaller lake is found on this line, called Loch Oich, 3½ miles long, from $\frac{1}{16}$ to ½ of a mile wide, and 26 fathoms in depth in the deepeſt part, its bottom being a ſoft mud. Loch Doughfour, the remaining one of the four, is 1¼ mile long, about ¼ of a mile wide in its wideſt part, and about 40 feet deep. The number of ſwing bridges is 25; there are 5 culverts with 1 to 4 arches each, and an aqueduct bridge of 4 ten-feet arches at Ley Bridge: the deep-cutting near Laggan is to be 45½ feet deep on the ſummit, and is eſtimated to coſt 11,262l. New courſes are required to be cut for the river Spean, and at Fort Auguſtus for the river Neſs; the ſteep hills adjoining, rendering it neceſſary for the canal to occupy the old bed of the river for ſome diſtance in thoſe places. A large weir is to be made at the eaſt end of Loch Doughfour, to hold up its waters to the level of Loch Neſs, and ſeveral ſmaller weirs are to be made. Loch Oich is to be deepened 1540 yards in length, at the expence of 11,550l. This canal is moſt amply ſupplied with water on the ſummit, not only for the lockage, but for the working of mills out of the different pounds, which will doubtleſs hereafter prove of immenſe advantage to the country. In 1774 Mr. *Watt* was employed to ſurvey this line, who eſtimated a 12 feet deep canal, in the place of the preſent one, to coſt 164,031l., excluſive of the land. In 1801 Mr. *Thomas Telford* was employed by Government to ſurvey the canal above deſcribed, aſſiſted by Mr. *Murdoch Downie*, very full particulars of which will be found in the *Reports*, printed by order of the houſe of commons 14th June 1803 and 10th of April 1804; in which Mr. *William Jeſſop*'s eſtimate, amounting to 474,531l. (excluſive of 23,000l. for land and mooring-chains) is given; and walled locks are recommended, on account of the loſs of time in filling the chambers of thoſe unwalled. By the firſt act above, 20,000l., by the next 75,000l., and by the laſt 50,000l. of the public money were granted, for carrying on this great work, under the direction of Mr. *Thomas Telford*. In October 1804, ſeven miles in length next Inverneſs were digging, and the entrance baſons were in hand. In Auguſt 1805, the new channel for the river Neſs was cutting, the firſt lock new Inverneſs was building, 1000 men being employed at this end. It is propoſed to place mooring chains on the ſhores of Lochs Neſs and Lochy, on account of their being too deep for good anchorage. On Loch Neſs government have had a galley of 37½ tons burthen ſince 1727, in which period, to 1803, five of them had been worn out: the worm ſo fatal to wood in ſome waters is not troubleſome here. At Inverneſs the ſpring tides riſe 11 to 15 feet, and the neap tides 7 feet; at Fort William they riſe 12 and 5 feet. Cromarty Bay in Murray Firth, about 18 miles eaſt of the beginning of this canal, was ſurveyed by Mr. *Thomas Telford* in 1801; the ſpring tides here riſe 14 or 15 feet, and the two piers of this harbour appear to offer a ſafe retreat for ſhips, ſecure from every wind, and where warehouſes are only wanting for the accommodation of a large fleet.

Itching River. Acts 16 and 17 of Cha. II., and 7 and 35 of Geo. III.—The general direction of this navigation is nearly north, for about 14 miles, in Hampſhire; it is but little elevated above the ſea; its objects are the ſupply of Wincheſter with coals, deals, &c. and of Southampton with flour and other agricultural products, and the trade between theſe towns. At Northam it is joined by the *Southampton and Saliſbury* canal. Southampton is the 68th Britiſh town, with a population of 7913 perſons; and Wincheſter the 103d, with 5826 perſons. It commences in the tideway in *Southampton Water* near Southampton, and terminates at Wincheſter. This navigation is the ſole property of *James D'Arcy*, Eſq.; and he and his predeceſſors were the ſole carriers, or nearly ſo, thereon, until 1795, when commiſſioners were named, in the above act, for fixing rates of tonnage, on payment of which it is in future to be a free navigation. It was intended to widen the channel between Woodmill and the Roman ditch, and to erect pound-locks where neceſſary.

Ivel River. Act 30 Geo. II.—The direction of this river is nearly ſouth, for about 11 miles, in the county of Bedford; it is not very greatly elevated; its objects are the ſupply of the towns of Biggleſwade, Shefford, and the adjoining country, with coals, deals, &c. and the export of farm produce. It commences in the great *Ouſe* river at Temsford, and terminates at the town of Shefford. On the lower end of this navigation, ſluices with ſeparate and moveable upright planks inſtead of gates are in uſe, as before mentioned. Soon after the paſſing of the act, the navigation was completed to Biggleſwade; but the remainder of the diſtance to Shefford, $5\frac{1}{4}$ miles, has not yet been made navigable, for want of money. In the preſent year (1805) Mr. *Benjamin Bevan* was employed to ſurvey and eſtimate the expence of this part, which he ſtates at 5900l.; the riſe about 26 feet, to be effected by 5 locks; the toll on this diſtance is to be 1s. 6d. per ton. It is ſtated that the part of this navigation below Biggleſwade has, in the laſt ſeven years, produced a net 400l. per annum, towards the reduction of the debt at firſt incurred. Several years ago the *Biggleſwade and Hertford* canal was propoſed to join this river at Biggleſwade.

Ivelchester and Langport Canal. Act 35 Geo. III.—The direction of this navigation is nearly eaſt for about 7 miles in the county of Somerſet: it is not much elevated: its objects are the import of coals and export of farming products; Langport and Ilcheſter, or Ivelcheſter, are conſiderable towns; it commences in the *Parret* below the town of Langport, and terminates at the town of Ilcheſter, following the courſe of the Yeo river part of the way, and the remainder by a canal; the company were authorized to raiſe 8,000l., the amount of ſhares being 50l. each: half-mile ſtones are to be erected on this navigation.

Kennet River. The courſe of this river is nearly eaſt for about 20 miles in the county of Berks, it has a conſiderable elevation: its objects are the ſupply of Newbury, the export of farming products, and forming part of the moſt direct communication between London and Bath and Briſtol; Reading and Newbury are conſiderable towns. It commences in the *Thames* river about a mile below Reading, and terminates in the *Kennet and Avon* canal a little above Newbury; on this navigation unwalled locks were very early in uſe; in Feb. 1800 it was propoſed to improve this navigation through the borough of Reading. This company has given notice that as carriers, they will not be anſwerable for the damage goods may ſuſtain by fire or unavoidable accidents. Immenſe beds of Peat are found near Reading, which is uſed for conſiderable diſtances as a manure.

Kennet and Avon Canal. Acts 34, 36, 38, 41, and 45 of Geo. III.—The general direction of this canal is nearly eaſt for $55\frac{1}{2}$ miles in the counties of Somerſet, Wilts, and Berks. The middle part is conſiderably elevated, and croſſes both the weſtern and eaſtern branches of the grand-ridge, the part between theſe points, croſſing the heads of the valleys which fall to the ſouthern coaſt, while the ends are in thoſe vales falling to the *Briſtol Channel* and the *Thames;* its objects are a communication between Briſtol, Bath, and London, and the ſupply of the country weſt of Hungerford with coals from the mines connected with the *Somerſetſhire Coal* canal, which joins at Monkton Combe; at Widford it connects with the *Dorſet and Somerſet* canal, and at Semington with the *Wilts and Berks* canal. Bath is the 12th Britiſh town, with 32,200 inhabitants; Devizes is the 69th, with 7,909 perſons; Bradford the 78th, with 7,302 perſons; and Trowbridge the 104th or 105th, with 5,799 perſons; Melkſham, Hungerford, and Newbury, are alſo conſiderable towns on or near this canal. This canal commences in the *Avon* river at Dole-Mead in Bath, and terminates in the *Kennet* river a little weſt of Newbury; the branches that were at firſt propoſed to Calne and Chippenham, have been ſuperſeded by the *Wilts and Berks* canal, and its branches. From the *Avon* to near Bathampton $\frac{3}{4}$ of a mile is a riſe of $56\frac{1}{2}$ feet; thence to Trowle bridge, $10\frac{1}{2}$ miles is level; thence to Devizes, $9\frac{1}{4}$ miles, is a riſe of $30\frac{1}{2}$ feet; thence for 20 miles along the ſummit-pound (and through the tunnel of $2\frac{3}{4}$ miles, at firſt propoſed) to Crofton; thence to Hungerford is ſix miles, with a fall of 104 feet; and thence to the *Kennet* near Reading, 9 miles, is a fall of 72 feet. By the ſecond act, the company were authoriſed to raiſe a part of their ſummit-pound at its eaſtern end, ſo as to paſs the ſummit by a moderate deep-cutting inſtead of the tunnel above mentioned, and to ſupply the new ſummit with water by a large ſteam-engine. This canal is calculated for 50 ton boats; at Trowbridge there is a baſon 129 yards long and 60 wide, and another between Lyncombe and Widcombe. There is a conſiderable deep-cutting near Burbage: there are two large ſtone aqueduct bridges over the *Avon* river, one called Dundas, the other is at Avon-cliff. Progreſs was firſt made in completing parts of this canal at its eaſtern end, and in October 1798, the ſame was opened from Reading to Hungerford; in July 1799 the ſame was opened to Great Bedwin, near the beginning of the ſummit: in May 1801, the other end of the line was opened from Bath to Devizes. The company were authoriſed to raiſe 810,000l. beſides a farther ſum by the laſt act; the original ſhares were 120l. each, but a great number of defaulters appeared among the ſubſcribers, (no leſs than 450 ſhares it was ſaid) and thoſe remaining being called on for 17l. 4s. $7\frac{1}{2}$d. on each, made the amount of theſe old ſhares 137l. 4s. $7\frac{1}{2}$d. each, before the act of 41 Geo. III. reſtrained any further calls on their ſhares, and created a new ſet of ſhares of the amount of 60l. each. The ſhares of ſeveral diſcontented proprietors were directed to be purchaſed. This canal paſſes through Sydney-gardens near Bath, which are laid out and appropriated to pleaſurable parties like our Vauxhall gardens. The rates of tonnage are from 1d. to $2\frac{1}{2}$d. per ton per mile on different goods, and others are fixed for the diſtance between Bath and Devizes, for which ſee *Phillips's* 4to. *Hiſtory, Appendix,* pages 142 and 143. Mr. *John Rennie* is the engineer, whoſe ſuperior ſkill has been ſhewn in ſurmounting the great difficulties that have attended the conſtruction of this canal: between Avon-Cliff and Bradford, a ſingle ſlip coſt, it is ſaid, 1000l. repairing. A canal paſſing through nearly this tract of country was propoſed in 1754. The new ſhares in 1802 bore a premium, notwithſtanding no intereſt is to be received on them until the line is completed, which was required by the firſt act to be done in the next year, (1806); we ſincerely wiſh this may be the caſe. Some years ago it was propoſed to extend a branch of the *Baſingſtoke* canal to join this at Hampſtead: in 1796 there was an intention of extending this canal by the ſide of the *Avon* to Briſtol.

KETLEY CANAL. The general direction of this canal, or water-level, is about E.; originally it was about 1½ mile in length, in the county of Salop; it has a great elevation, being within 7 or 8 miles of the grand ridge on its weſtern ſide; its objects are the conveyance of coals, iron-ore, and lime-ſtone, the export of heavy iron goods, &c.; it was contrived by Mr. *William Reynolds*, and cut in 1788 at the ſole expence of Meſſrs. *William Reynolds and Co.* and in the year 1793, 1 mile and 188 yards of this level at its eaſt end were ſold to the *Shrewſbury* company, and made part of their canal; the price was 840l. half the original coſt, with the condition that Meſſrs. *Reynolds and Co.* ſhould pay 2d. per ton per mile for their goods paſſing on the *Shrewſbury* canal. This canal now, therefore, conſiſts of about three furlongs of level connecting with the *Shrewſbury* canal, at the head of the Wom bridge inclined-plane, and having at its other extremity an inclined plane of 73 feet perpendicular fall to the Ketley iron-works; this inclined plane was the firſt that was brought into practice in England for the paſſage of boats, and in 1789 a copper medal or half-penny was ſtruck to commemorate the ſame. The boats uſed hereon are 20 feet long, 6½ feet wide, and 3 feet 10 inches deep, carrying 8 tons; they are floated into a ſhallow lock at the top of the plane in order to place them upon the wheeled carriage or cradle, which carries them down the plane, after the water in the lock is drawn off into a ſide-pond, to be pumped up again by a ſteam-engine into the upper pound, and by which no water is loſt out of the upper pound or water-level. The inclined plane is double, and a deſcending loaded boat draws up an empty one or but about one-third laden, by means of ſtrong ropes winding round a barrel at the head of the plane, the velocity being regulated by a brake-wheel; of this plane we have before ſpoken. Several of theſe ſmall boats linked together are towed along the level by one horſe, and to guide them round the projecting turns of the bank, ſlide-rails are placed thereon.

*Keyingham-Level.* In the year 1802, Mr. *William Chapman* made a ſurvey for a navigation, and drainage-cuts, from the *Humber* river at Stone-creek, to Rooſs-bridge and Owſtwick-carr gate, in the Eaſt-Riding of Yorkſhire, the eſtimated expence thereof being 1500l.; the canal was propoſed to paſs near the town of Keyingham, its objects being the import of coals, &c. and the export of agricultural articles.

KIDWELLY CANAL. The length of this canal is about 3½ miles, in Caermarthenſhire, in South Wales, it is the private property of Mr. *Keymer*; it extends from the tide-way at the town of Kidwelly to Mancha coal and lime-works, belonging to Mr. Keymer, through whoſe eſtate the canal is alſo cut: its object is the export of lime and coals.

LAGAN NAVIGATION, (*Ireland*). This is one of the navigations which the Iriſh parliament have aſſiſted with ſums of money, with the view of facilitating the working of the collieries with which it connects; for this navigation and its collieries, various ſums of public money were advanced between 1753 and 1770, amounting to 40,304l.

LANCASTER CANAL. Acts 32, 33, 36 and 40 of Geo. III.—The general direction of this canal is nearly S. for 75¾ miles, in the counties of Weſtmoreland and Lancaſter; the greater part of its northern end ſkirts along near the ſea-coaſt, but the ſouthern end is conſiderably elevated, croſſing within two miles of its termination the Haſlingden and Liverpool branch from the grand-ridge. Its objects are, the interchange of the lime-ſtone of the northern parts, for the coals and cannel of the ſouthern parts of the line, the ſupply of Lancaſter and Preſton, &c.: it is to connect with the ſea at Glaſſon Dock by a cut of 4 miles from Galgate on the line of the canal; it croſſes the *Loyne* and *Ribble* rivers, but without connecting with them, and it likewiſe paſſes under the *Leeds and Liverpool* canal. Preſton is the 37th Britiſh town with 11,887 inhabitants, Wigan is the 42d, with 10,989 perſons, Lancaſter the 56th, with 9,030 perſons, and Kendal is the 88th, with 6,892 perſons; Burton, Garſtang, Kirkham, and Chorley are alſo conſiderable towns on this line. This canal commences in a baſon at Kirkby-Kendal, and terminates in another at Weſt Houghton: to Wharton-Craggs lime-works there is to be a cut of 2½ miles, and another of 2⅞ miles to Duxbury near Chorley. From the baſon at Kendal to Greenhead farm (through the Hincaſter or Leven tunnel) is 5⅛ miles and level; thence to near Borwick, (near the Wharton branch) 9¾ miles, is a fall of 65 feet; thence to the ſouth ſide of the meadows ſouth of Preſton is 42⅝ miles and level! thence to Clayton Green 3⅛ miles is a riſe of 222 feet, and thence to Weſt Houghton 15⅝ miles is level; the Wharton and Duxbury cuts are level. This canal is 7 feet deep, the boats are 56 feet long and 14 feet wide, carrying 60 tons; and the Glaſſon branch has a fall of about 52 feet. There are two tunnels, one at Hincaſter near Leven's Park of about 800 yards long, and another through the Whittle Hills near Chorley, which proved a moſt difficult one to execute; at Aſhton near Lancaſter there is an amazing piece of deep-cutting. At Lancaſter there is a moſt ſurpriſing aqueduct bridge 51 feet high, over the *Loyne* river, conſiſting of 5 arches of 70 feet ſpan each. (See our article BRIDGE.) There are other aqueducts over the *Ribble* at Preſton, the Wyre at Garſtang, the Beeloo near Bethorn, &c.; and it is paſſed on an aqueduct 60 feet high near Bark-mill not far from Wigan by the *Leeds and Liverpool* canal. At Kendal the canal is ſupplied with water by a feeder of 1 mile in length from the river Mint: water from all mines within 200 yards may be taken. The part of the line between Wheelton (near to Clayton Green) and the ſouth end of the long level is at preſent ſupplied with a rail way, but we believe only as a temporary meaſure. Mr. *James Brindley* was employed in 1772 to ſurvey a part of this line, the whole of it was ſoon after ſurveyed by Mr. *Robert Whitworth*, and in 1791, Mr. *John Rennie* was employed, who has had the direction of the works upon it, which will redound to his laſting credit. The company is authoriſed to raiſe 414,000l. in 100l. ſhares, and 200,000l. more in ſhares of 30l. each. In July 1796, the laſt arch of the Lancaſter aqueduct was completed: in September 1805, it was ſtated that the ſhares divided 1l. per cent. From Bolton to Lancaſter and thence to Preſton it was opened in November 1797, and in a few years after the whole of the long level was completed. In June 1803, the Whittle tunnel was completed, and 1½ mile of the rail-way, ſo that coals paſſed from Weſt Houghton to Bramber-bridge, and in 1805, the remainder of the rail-way was opened for conveying coals to Preſton, Lancaſter, &c. At Heſt this canal paſſes along cloſe to the ſea beach. The rates of tonnage are, for coals 1½d. per ton per mile; for lime-ſtone, ſlate, ſalt, bricks, ſtone, iron-ore, gravel, ſand, clay, and manures ½d. per ton per mile; for lime and iron 1d. per ton per mile, and for timber, wares, and merchandize, 2d. per ton per mile. Coals are not to paſs the intended locks N. of Chorley under 2s. 3d. per ton, which is to paſs them for 18 miles N. of Chorley. It is provided in the *Ulverſton* canal act (33 Geo. III.) that coals from this canal may croſs the bay of Morecambe to that place without being ſubject to the ſea duty.

LARK RIVER. This river (ſometimes called the Mildenhall) has its courſe nearly S. E. for about 22 miles in the county of Suffolk, after ſkirting the bounds of Cambridge for ſome miles. Bury St. Edmunds is the 71ſt Britiſh town, with a population of 7,655 perſons; Mildenhall is alſo a conſiderable town on the line of this navigation, which commences in the great *Ouſe* river at Prick-willow, (about 4½ miles below Ely) and terminates at Bury St. Edmunds. Its objects are the import of coals, deals, &c. and the export of farming products. The lower part of its courſe is embanked on both ſides through the fens. It is generally very ſhort of water in the autumn. In 1789, this river was propoſed to be croſſed by the *Biſhopſtortford and Wilton* intended canal; and in 1802 it was propoſed to be joined at Bury St. Edmunds by the *Stowmarket and Bury* rail-way.

LEA RIVER. Acts 12 Geo. II. and 7, 19, and 45 of Geo. III.—The general direction of this river is almoſt north for about 28 miles, between the counties of Middleſex and Eſſex and in Hertfordſhire; it is not much elevated. Its objects are the ſupply of Hertford and all the ſurrounding country with coals, deals, &c. and the export of farming products, of which malt from Ware forms a conſiderable part. At Bromley near Bow it connects with the *Limehouſe* canal, and near Hoddeſdon it is joined by the *Stort* river. Hertford, Ware, Hoddeſdon, Waltham-Abbey, Enfield, and Stratford are conſiderable towns on or near this navigation. It commences in the *Thames* river at Bow-Creek near the *Eaſt-India Docks*, and terminates in the town of Hertford: it has a ſhort cut to the town of Waltham-Abbey. This river, which ſeems ſubject to floods, was originally made navigable in ſome places by weirs and fluſh-ſluices, or turnpikes. In 1767, Mr. *John Smeaton* calculated one of thoſe ſluices to let down 1429½ cubic feet of water per minute on an average, a conſumption which greatly injured the mills; the early pound-locks erected on this river were without walled chambers. In 1771 ſome of the turnpikes were removed and locks built; in 1781, Mr. *Smeaton* was again called in to give an opinion on the very leaky ſtate of the locks. In 1772, and again in 1802, this river was propoſed to be joined at Waltham-Abbey by the *London and Waltham-Abbey*, with another junction therewith at Lee-bridge; and in 1792, it was propoſed to be joined at Hertford by the *Leiceſter and London* canal. Several years ago the *Biggleſwade and Hertford* canal was propoſed to join this river at Hertford. Between Hertford and Ware, the *New River* or aqueduct for the ſupply of London, has its riſe, partly out of the chalk hills, and partly by a feeder out of this river, and purſues its devious courſe for near 40 miles. This great work was begun by Sir *Hugh Middleton* in 1608; in 1773, Mr. *James Sharp* ſuggeſted the making of the New River navigable, and continuing it by a level cut to the *Thames* near Reading. In 1803, Mr. *John Rennie* was employed by government to ſurvey the lower part of the courſe of the *Lea* river, and to conſtruct embankments acroſs, for filling this extenſive vale with water in caſe of an invaſion: the gates intended to produce theſe effects, are veſſels that can on the ſhorteſt notice be floated to and ſunk in their proper places, to ſtop the water, as before deſcribed.

*Leatherhead and Thames Rail-way.* In 1801, it was propoſed to make a rail-way from a baſon to be made on the banks of the *Thames*, in Weſt Moulſey (oppoſite Sunbury) to the town of Leatherhead in Surry, through the pariſhes of Walſton, Cobham, Stoke-Dawbernon, Little Bookham, Great Bookham and Fetcham.

LEE RIVER, (*Ireland.*) For improving the navigation of this river, the Iriſh parliament between 1753 and 1772, granted 2,000l. of the public money.

LEEDS AND LIVERPOOL CANAL. Acts 10, 23, 30, and 34 of Geo. III. The general direction of this canal is between N. E. and E. by a very crooked courſe of 130 miles in the counties of Lancaſter and York; it croſſes the grand-ridge by a tunnel, near Colne, and at Red-Moſs and Aſpule croſſes the Haſlingden and Liverpool branch of the grand-ridge. Its objects are a communication between the ports of Liverpool and Hull, the export of the immenſe ſtores of coals, cannel, and lime-ſtone, that are found on parts of its courſe, and the ſupply of the great towns thereon with the agricultural products of the intermediate country. At Brier's-mill it connects with the *Douglas* navigation (now belonging to this company, by a purchaſe under 23 Geo. III.); near Bark-mill not far from Wigan it croſſes the *Lancaſter* canal (but is 60 feet above it on an aqueduct-bridge.) At Church it connects with the *Haſlingden* canal, at Skipton with *Thanet*'s canal, and at Windhill with the *Bradford* canal. Liverpool is the 4th Britiſh town with 77,653 inhabitants; Leeds is the 8th, with 53,162 perſons; Blackburn is the 36th, with 11,980 perſons; Wigan is the 42d, with 10,989; Bradford is the 95th, with 6,393 perſons, and Hunſlet the 104th or 105th, with 5,799 perſons: Ormſkirk, Chorley, Burnley, Colne, and Skipton are alſo conſiderable towns on or near this line; which commences in the town of Liverpool (on the bank of the *Merſey*, but does not connect therewith, and terminates in the *Ayre and Calder* navigation in the town of Leeds; there is a cut to Ighton-hill collieries, another to Mr. Walton's Altham collieries; and proviſion is made for cuts to be made by the earl of Balcarras and Mr. Shuttleworth between their coal-works and the line. The old baſon at Liverpool is 52 feet above low-water mark in the *Merſey* river, from thence to Newborough, 28 miles, is level; thence to the beginning of the deviation that was laſt made in the line, near to the town of Wigan, 7 miles, is a riſe of 30 feet, by 5 locks, (this laſt length being ſometimes called the *Upper Douglas* navigation, of which it formerly was a part), thence to Bradſhaw-hill near Aſpule 3 miles, has a riſe of 279 feet, by 28 locks, (the *Lancaſter* canal being croſſed in this diſtance) thence to the aqueduct over the Derwent near Blackburn, 19¼ miles, is level; thence to Grimſhaw near Blackburn, ¾ of a mile, has a riſe of 54¼ feet, by 7 locks; thence to the end of the deviation at Barrowford near Colne is 24 miles and level; and thence to the beginning of the ſummit pound near Colne is ¾ of a mile with a riſe of 67¾ feet, by 7 locks. The ſummit-pound, paſſing through the Foulridge tunnel, extends to near Thornton, about 6¾ miles and level; thence to Holme-bridge near Gargrave is about 7½ miles, with about 150 feet fall, by 15 locks; thence to Gawthorpe-hall near Bingley is 17 miles and level; thence to the junction of the *Bradford* canal is about 4 miles and 100 feet fall by 11 locks; and thence to the *Ayre and Calder* navigation at Leeds is about 12½ miles, and 160 feet fall, by 18 locks: the whole lockage being 840½ feet by 91 locks, which are each 70 feet in length, and 15½ feet in width; the breadth of the canal at top is 42 feet, and it is 4½ feet deep in water. The boats are keel-bottomed, and carry 30 tons of goods, with which they can go down the *Ayre* and *Ouſe* as far as Selby; between Leeds and Wigan, 100 flatts of 42 tons burthen are employed in the coal and cannel trade, paſſage-boats alſo ply regularly on this part. At Leeds there is a fine baſon, and there are ſpacious warehouſes belonging to this company at the north-eaſt corner of Liverpool town, and it was intended in 1801, to conſtruct a new baſon from the North Graving-Dock on this canal, to the top of Plumbe ſtreet, for which

7000 cubic yards of earth were to be excavated, and the whole to be lined by 1200 cubic yards of ſtone maſonry. The coals are thrown out of the boats on a branch that proceeds near to the *Merſey*, and ſlide down a ſteep bank to a yard by the water ſide. At Foulridge there is a tunnel of 1030 yards in length, and 23 yards below the higheſt point of the hill; the ſoil of which proved ſo very looſe, that only 720 yards could be worked under-ground, the remainder was obliged to be opened from above, from 10 to 20 yards deep, and 20 to 30 yards wide at the top, although it was ſupported with immenſe labour and expence by timbers to prevent its falling, until the tunnel arch was formed, which is 18 feet high and 17 feet wide withinſide; it is arched with ſtone. At Furnloy near Burnley, there is another tunnel. At Cottingley below Bingley, and near Gargrave there are conſiderable aqueduct bridges over the Ayre river, and ſeveral leſſer ones in different places. Mr. *Longbottom* made a ſurvey for this canal in 1767, which was reviſed by Mr. *James Brindley* in 1768, under whom the canal was begun, after which Mr. *Robert Whitworth* and Mr. *Fletcher* were employed thereon. In 1770, the eaſtern end of the line was completed from Leeds to Holme-bridge, a diſtance of 33½ miles; about the end of 1794 this was extended to near Foulridge. May 1, 1796, the Foulridge tunnel was completed and the line opened to Burnley. In May 1801, the Furnloy tunnel was finiſhed, and the navigation extended to Enfield within 4½ miles of Blackburn; and in July 1801, the Altham branch was opened. The weſtern end of the line was begun as early as the other, and in 1770 the ſame was opened from Liverpool to the *Douglas* old navigation at Newborough, 28 miles; and on 19th October 1774, the preſent navigation was completed to Wigan. This company was authorized to raiſe 600,000l. the amount of ſhares 100l. The rates of tonnage are, on lime-ſtone and other ſtones ½d. per ton per mile, on coals and lime 1d. and on all other articles 1½d. per ton per mile. No wharfage to be taken unleſs goods remain 6 hours. In September 1805, the company propoſed lowering their rates of tonnage on the *Douglas* lower navigation. About the year 1794, a branch of the *Mancheſter Bolton and Bury* was propoſed to join this canal at Red-Moſs near Wigan. In September 1802, it was propoſed to make a branch from this canal near Wigan to *Bridgewater*'s canal at Pennington; alſo a branch or rail way from it to Low-hall collieries.

LEICESTER NAVIGATION. Acts 31, 34, (for *Aſhby* Canal) and 37 of Geo. III.—The general direction of the line of this navigation is about ſouth, following nearly the courſe of the Soar river, for 14 miles in the county of Leiceſter, its Charnwood Foreſt branch is conſiderably elevated. Its objects are the ſupply of Leiceſter with coals, deals, and general merchandize, the export of coals and limeſtone from the mines on its branches, and the farming products of the country. On the completion of the *Leiceſter Union* canal it will become a conſiderable thoroughfare. At Turn-water Meadow in Coſſington, it is joined by the *Leiceſter and Melton-Mowbray* navigation. Leiceſter is the 22d Britiſh town with a population of 16,953 perſons; Loughbourough and Mount-Sorrel are alſo conſiderable towns on the line. It commences in the baſon of the *Loughborough* navigation at that town, and terminates in the *Leiceſterſhire and Northamptonſhire Union* canal, at Leiceſter. From the baſon at Loughborough, a *rail-way* branch of 2½ miles, and a riſe of 185 feet, extends weſtward to a baſon at Foreſt-lane, at the eaſt end of the Charnwood Foreſt *water-level*, which level extends 8⅛ miles to near Barrow-hill, having a ſide cut of ¼ of a mile to Thringſton-bridge, and level. From the weſt end of the water-level a rail-way extends ⅞ of a mile further to Clouds-hill lime-works, and there connects or very nearly ſo with a branch of the *Aſhby-de-la-Zouch* canal; there is a ſhort rail-way branch of ſix chains to Barrow-hill lime-works; the Thringſtone-bridge branch is alſo continued by a rail-way to Coal-Orton in two branches of 1½ mile, and another of ¼ of a mile to Swannington-common coal-works. From *Loughborough* baſon to the junction of the *Leiceſter and Melton-Mowbray* navigation it is 3 miles, and level, and thence to the *Leiceſterſhire and Northamptonſhire Union* the diſtance is 11 miles, with a riſe of 45 feet. On Charnwood Foreſt there is a reſervoir for ſupplying the water-level, and a feeder of ¾ of a mile in length to convey the water to it. Near the weſt bridge in Leiceſter there is a baſon for the uſe of this navigation. Mr. *William Jeſſop* was the engineer; in December 1793 the part of the line between Loughborough and Sieby, near Mount Sorrel, was opened, and in February 1794 the remainder of the ſame to Leiceſter was opened. The company was authoriſed to raiſe 84,000 l. The rates of tonnage are various: ſee *Phillips's* 4to. *Hiſtory*, *Appendix*, p. 12. On the making of the *Aſhby* canal, with branches to the neighbourhood of the collieries connected with the Charnwood level, the company were allowed 2s. 6d. per ton on all coals dug in Swannington, Coal-Orton, or Thringſtone pariſhes, and carried through Blackfordby, on the *Aſhby* canal. The company are authoriſed to make rail-ways to any mines within 2000 yards of the water-level; and are to guarantee the *Loughborough* company a receipt of 2000 l. per annum, on condition of their taking 1 s. 6 d. or leſs per ton (but not leſs than 10 d.) for coals paſſing from Loughborough to the *Trent* river.

*Leiceſter and London Canal.* About the year 1792 printed propoſals and a plan were circulated, for a canal from the *Leiceſter* navigation at that town to the *Lea* river at Hertford, a diſtance of 77 miles; paſſing Market-Harborough, croſſing the *Nen* river near Wellingborough, and connecting with the *Ouſe* navigation at Bedford; its profeſſed object, as a rival to the *Grand Junction*, was the forming of the ſhorteſt communication between London, Liverpool, Hull, and Lynn, and the intermediate large trading towns, mines, &c.

LEICESTER AND MELTON-MOWBRAY NAVIGATION. Acts 31 and 40 Geo. III.—The general direction of this navigation is nearly E. following the courſes of the Wreak and Eye rivers, for about 12 miles, in the county of Leiceſter; it is not greatly elevated in any part, its objects are the ſupply of Melton-Mowbray with coals, deals, &c. and the export of the farming products of the country; it commences in the *Leiceſter* navigation at Turn-water Meadow in Coſſington, and terminates in the *Oakham* canal, at the town of Melton-Mowbray. The company were authoriſed to raiſe 40,000l. The original rates of tonnage may be ſeen in *Phillips's 4to. Hiſtory*, *Appendix*, p. 13, but theſe were altered and increaſed by the late act above, and ſeveral regulations made reſpecting tolls with the *Oakham* company. This navigation was completed in a few years after the paſſing of the firſt act.

LEICESTERSHIRE AND NORTHAMPTONSHIRE UNION CANAL. Acts 33 and 45 Geo. III.—The general direction of this canal is nearly S.E. by a crooked courſe of 43¾ miles in the counties of Leiceſter and Northampton; its middle part is conſiderably elevated, and ſkirts along the eaſtern ſide and near to the grand-ridge for ſeveral miles: its objects are the formation of a junction between London, Hull, and Lynn; the ſupply of the country through which it paſſes with coals, deals, &c. and the export of farming products; it is to connect at Northampton with a *rail-way* branch of the *Grand Junction*. Leiceſter is the 22d Britiſh town, with a population of 16,953 perſons, and Northampton is the 85th, with 7,020 perſons, Market-Harborough is alſo a conſiderable place near the line. This canal commences in the *Leiceſter* navigation in the town of Leiceſter, and terminates in the *Nen* river at the town of Northampton; there is a cut of $3\frac{3}{4}$ miles in length to Market-Harborough. From the *Leiceſter* navigation to Fleckney near the Saddington tunnel is $12\frac{3}{4}$ miles, with 160 feet riſe; thence to near Great Oxenden $13\frac{1}{2}$ miles are level; thence in $\frac{1}{8}$ of a mile is 50 feet riſe; thence the ſummit-pound extends through Oxenden and Kelmarſh tunnels to near Maidwell, $4\frac{7}{8}$ miles and level; thence to the junction of the North river near Northampton are $11\frac{3}{4}$ miles, with a fall of $197\frac{1}{2}$ feet, and thence to the head of the *Nen* navigation is $\frac{3}{4}$ of a mile and level. The Market-Harborough cut is level. At Gumley there are a baſon and warehouſes. There are four tunnels on this line, viz. at Foxton, of 1056 yards in length; at Kelmarſh, of 990 yards in length; at Saddington, of 880 yards in length, and at Oxenden, of 286 yards in length. On Oxenden and Kelmarſh brooks are the aqueducts for the ſupply over the ſummit-level, but flood-waters alone are to be taken. There are a great number of ſmall aqueducts over the ſtreams which it paſſes. Mr. *John Varley*, ſen. and Mr. *C. Staveley*, jun. are the engineers. In March 1800, the tunnel at Saddington was finiſhed, and the line opened from Leiceſter to Gumley, a diſtance of 17 miles; but ſmall progreſs appears to have been ſince made with the other three tunnels, and the remainder of the line, intended to form the union. The rates of tonnage on coals and coak are $2\frac{1}{2}$d. per ton, per mile, but not to exceed 5s. for any diſtance; for lime, lime-ſtone, dung, and manure $1\frac{1}{4}$d. per ton, per mile, but not exceeding 2s. 6d. per ton, on any diſtance; for live cattle, ſtones, bricks, tiles, ſlates, ſand, iron-ſtone, pig-iron, and pig-lead, 2d. per ton, per mile, and for other goods 3d. per ton, per mile; troops and government ſtores are exempted. Road-materials, and manures (except lime) for the uſe of the proprietors of lands on the pounds, may alſo paſs the locks when the water runs waſte thereat. The towing path may be uſed as a bridle and drift-way by the owners of adjoining lands. By the firſt act the company were authorized to raiſe 300,000l. ſhares 100l. each; the laſt act was for varying ſome parts of the line and amending the former one. About the year 1793, the *Uppingham* canal was in contemplation, and its junction with this canal is provided for in the firſt act above. In 1803 it was propoſed to alter and ſhorten the branch to Market-Harborough, and to make a feeder from Wiſtow brook; and in the ſame year Mr. *Thomas Telford* ſurveyed the line of country between Gumley baſon and Buckby wharf on the *Grand Junction* canal, propoſed as a ſubſtitute for the ſouthern part of the line to Northampton.

Leominster Canal. Acts 31 and 36 Geo. III.—The general direction of this canal is nearly W. by a crooked courſe of $45\frac{3}{4}$ miles, in the counties of Worceſter, Salop, and Hereford; its weſtern end is very conſiderably elevated; its objects are the ſupply of Leominſter and the country with coals from the Pinſax mines near its eaſtern end, and the export of iron, lime, and agricultural products: Kington, Preſteign, Leominſter, Ludlow, Tenbury, Cleobury-Mortimer, and Bewdley are conſiderable towns on or near to the line of this canal: it commences in the *Severn* river at Areley near Stour-port, and terminates at the town of Kington: it has two ſhort cuts to mills near Tenbury. From the *Severn* river to the eaſt end of the Pinſax tunnel it is 3 miles, with a riſe of 207 feet; thence through that tunnel, and the Souſnant tunnel to its weſtern end, it is 9 miles and level; thence to the river Rea aqueduct is 1 mile, with a fall of 30 feet; thence to Letwich brook, 7 miles, it is level; thence to Wiſton, $4\frac{1}{2}$ miles, is a riſe of 36 feet; thence to near Luſton, $5\frac{1}{4}$ miles, is level; thence to Leominſter, $1\frac{1}{2}$ mile, is a fall of 18 feet; thence to near Kingſland are $4\frac{1}{2}$ miles, with 64 feet riſe; thence to Milton are $3\frac{1}{2}$ miles, with 37 feet riſe; thence to Stanton-park are $2\frac{1}{2}$ miles, with a riſe of 152 feet, and thence to Kington are 4 miles, and level. At Pinſax is a tunnel of 3850 yards, and the other at Souſnant is 1250 yards in length. There are conſiderable aqueduct-bridges over the Rea river at Knighton, over the Teme at Woferton, and over the Lugg at Kingſland: a power is provided in the act for inclined-planes inſtead of locks, if the ſame ſhould be found moſt eligible; ſprings of water within 2000 yards of the line may be taken. Mr. *Thomas Dadford*, jun. is the engineer. In July 1796 the difficult tunnel at Putnal-field in Souſnant was finiſhed, and in November 1796, near 20 miles of canal, from Mamble coal-works to the town of Leominſter were opened, and coals, which before ſold there at 1s. 6d. per cwt. were at once reduced to 9d. per cwt.! On the 1ſt of June 1797, the entrance of the canal from the *Severn* was opened: ſince which conſiderable progreſs has been made in the works: in May laſt (1805,) the Pinſax mining company was propoſed, for opening new coal and iron mines near that place, on the line of the canal, which was expected to facilitate its completion. The *Leominſter* company have been authoriſed to raiſe 370,000l. The tonnage rates are too long for our room, they will be found in *Phillips's* 4to. *Hiſtory*, *Appendix*, p. 5 and 6. About the year 1794, the *Welſhpool and Leominſter* canal was propoſed to join this at Woferton.

Liffey River, (*Ireland*). The direction of this river is nearly weſt, in Dublin county, from the bay of Dublin to the entrance baſon of the *Grand Canal* in Dublin city, where alſo are a Harbour and Docks that have been improved, under Mr. *William Jeſſop;* the ſpring tides riſe only 13 feet at theſe dock-gates. In the year 1800 it was propoſed to avoid the bar at the mouth of the *Liffey*, by cutting a new channel or canal for ſhips from Dunleary to Kingſtead dock; it was alſo propoſed to make Dalkey ſound a ſafe harbour, and to make a cut from thence to the *Grand Canal* baſon; the bill for this purpoſe was paſſed by the commons, but was rejected by the houſe of lords. Ormond bridge, on this river, was carried away by a flood, and in September laſt (1805,) the corporation of Dublin harbour offered premiums for the beſt plans for a new bridge at this place.

Limehouse Canal. The direction of this canal is about N.E. for $1\frac{1}{2}$ mile, in the county of Middleſex; it is but little elevated above the level of the ſea; its object is to ſhorten the navigation between the *Lea* river and the port of London, by avoiding the circuit round the Iſle of Dogs; it commences in the river *Thames* near Limehouſe church, and terminates in the *Lea* river at Bromley near Bow, having a riſe of $17\frac{1}{2}$ feet. This canal was cut at the expence of the *city of London*, in an early part of the preſent reign, and its locks, which are of wood, and its other works, form a great contraſt to the improved locks and appendages of modern canals. In 1773 a cut from the intended *London and Waltham-Abbey* canal was intended to join this near Limehouſe church.

Limerick Canal, (*Ireland*). This canal was cut near 40 years ago from the town of Leitrim to a moraſs within a ſhort diſtance, for the purpoſe of bringing turfs, to ſupply the town of Limerick with fuel, and which by their cheapneſs ſuperſeded in a great meaſure the uſe of coals, which coming by a long coaſt-ways navigation were very dear.

*Liſkeard Canal.* In 1777, Mr. *Edmund Leach* propoſed a canal, or rather a ſyſtem of water-levels and inclined-planes, from the tide-way in the *Looe* river, at Sand-place in Morval to Bark-mill-bridge, in St. Clear; this was propoſed to be accompliſhed by two levels of 9 and 6 miles in length, (one of which, in its ſerpentine courſe, went within ¼ a mile of Liſkeard town,) connected with each other and the river below by two inclined planes for boats, the principles of which have been already explained; the eſtimate was 17,500l. The objects of this navigation were the carrying up of lime and ſea-ſand for manure, and exporting corn, &c.

*Liverpool and Runcorn.* About the year 1771, a ſurvey was made by Mr. *James Brindley*, for a canal from the town of Liverpool upon one level, to croſs the *Merſey* at Runcorn-gap, by an aqueduct bridge, and join the duke of *Bridgewater*'s canal; beſides the great width of the Merſey at this place, a tide, which riſes 14 feet, was alſo to be encountered.

*Llandovery and Llanelly.* In September 1801, notices were given for an intended canal from Spitty in the pariſh of Llanelly, on the *Burry* river, through Llangennech, Llanedy, Laudebye, Llandingar, &c. to Llandovery or Llanyneddyvi, in the county of Caermarthen in South Wales. The objects of this canal were ſince accompliſhed by the *Caermarthenſhire* rail-way, over nearly the ſame tract of country.

*London Canal.* In July 1802, a ſurvey was made for a canal, about in a weſt direction, for near 7 miles, in the county of Middleſex: commencing in the *London Docks*, (and thereby communicating with the *Thames* river,) to paſs Weſt's-gardens, the mount in White-chapel road, and Bethnal-green New road, acroſs Hackney road, through Middleſex-place acroſs Kingſland road, near Iron-monger's alms-houſes, to paſs north of Lady Lumley's alms-houſes at Hoxton, acroſs the city road below the turnpike-gate, acroſs Goſwell-ſtreet, ſouth of Goſwell-place, acroſs St. John's-ſtreet, north of Taylor's brewhouſe, under the field ſouth of the New-river head, over the valley at Bagnige-wells, acroſs Gray's Inn-lane at the weſt corner of the Welſh Charity-ſchool, acroſs the New road to the eaſt corner of Bedford nurſery, acroſs Tottenham court road between St. James's burying-ground and the New-river reſervoir, paſt the fronts of the Artichoke and Queen's-head public houſes, and acroſs the Edgeware road to the baſon of the *Grand Junction* canal at Paddington, the riſe in this diſtance being about 90 feet. The great number of bridges required, the paſſing of the field near Iſlington full of water-pipes in all directions, belonging to the New-river company, by an arch under the ſame, and a large embankment or aqueduct bridge near Bagnige-wells, were difficulties in the way of this project, but to which the ſubſcription for ſhares (which almoſt immediately filled to the amount of 400,000l.) would have been equal; had not the inability of the *Grand Junction* company to furniſh the water neceſſary for the lockage, and the oppoſition of ſeveral powerful land owners, on account of its making ſome alterations neceſſary in their building projects, fruſtrated the ſcheme altogether for the preſent. The weſtern branch of the *Grand Junction*, of which we have before ſpoken, was in contemplation at the time this canal was intended, and water was propoſed to be obtained thereby from the *Thames* for this canal, the Colne millers having it unfortunately in their power, to prevent any being obtained from that river; Mr. *John Rennie*, who gauged the ſtream of the *Thames*, in the dry ſummer of 1794, at Laleham (which is after it has received the main ſtreams of the Colne), found 1155 cubic feet of water to paſs in one ſecond of time, which is 184 times what would be required to be taken from this river higher up near Great Marlow, and brought by the *Grand Junction* level branches, for ſupplying the lockage of this canal, ſuppoſing 60 locks containing 1055 cubic feet each, to be uſed daily. After the oppoſing intereſts were found too ſtrong to leave any proſpects of carrying this canal, a faint effort was made to accompliſh a *rail-way*, through nearly the ſame line, but with no better ſucceſs. In 1773, Mr. *Robert Whitworth* made a ſurvey for the city of London, and recommended a line of canal from the *Lea* river at Lee-bridge, to near the ſame ſpot which the *Grand Junction* baſon now occupies at Paddington: it was intended as branches eaſt and weſt of the *London and Waltham-Abbey* canal.

*London Lynn and Norwich.* In the year 1785, Mr. *John Philips* publiſhed a thin 4to. treatiſe, to endeavour to call the public attention to a canal between the *Ouſe* river at the port of Lynn, and the *Thames* river at Limehouſe in London, with a branch to the *Yare* river at Norwich. It appears that Mr. *P.* travelled through the propoſed tract of country in 1779 and 1780, but took no levels or other neceſſary particulars, yet ventures to ſtate, that he could execute this canal, 36 feet wide, and 4½ feet deep, for 200,000l. And it is held out, that 28,000 oak Trees, to be planted on the banks of this canal, will, in 50 years, repay all its expences within 60,000l. In 1802 we are told that Mr. *Ralph Dodd* made an effort to revive this or a ſimilar ſcheme, and wiſhed to denominate it the North London Canal.

*London and Waltham-Abbey.* In the year 1773, at the inſtance of Mr. *James Sharp*, Mr. *Robert Whitworth* was employed by the city of London to ſurvey the line for a canal between the centre of the quarters in Moorfields, London, to the river *Lea* at Waltham-Abbey; a diſtance of 14 miles, almoſt in a north direction in the counties of Middleſex and Hertford; this line was to be level (and about 30 feet above ſpring-tides in the *Thames*,) there was a cut of ⅜ of a mile, and 33 feet fall propoſed to the *Lea* river at Lee bridge, and another of 4⅝ miles to Wellin's Farm near Paddington, with 49¾ feet riſe; nearly to the ſame level as the *Grand Junction* baſon now has; alſo another cut of near 2 miles to the *Limehouſe* canal near the church, with a fall of 42 feet (to the common neap tides in the *Thames*). The width was to be 60 feet, and depth 4½ feet; in Moorfields and near Holywell Mount, large baſons were intended; between Stamford-hill and High-croſs a very large embankment was neceſſary, another at Hackney brook, and another at St. Pancras brook; at Ponder's end was to be a deep-cutting to avoid the houſes; 15 turnpike road-bridges, and 22 road-bridges of leſſer ſize were neceſſary, the whole expence Mr. *Whitworth* eſtimated to be 98,229l. In 1802, this or a ſimilar ſcheme ſeems to have been in contemplation, but to join the *Thames* near Bell-wharf in Shadwell inſtead of the *Limehouſe* cut.

LOOE RIVER. The general direction of this navigation is nearly N. for about 3¼ miles, on the ſouth coaſt of Cornwall, it commences at the ſea near Eaſt Looe, (which is a conſiderable town,) and terminates at Morval bridge, near which, at Sand-place, it was, in 1777, propoſed to be joined by the *Liſkeard* canal; its objects are the carrying up of coals, and ſea-ſand as manure, and the export of agricultural products.

LOUGHBOROUGH NAVIGATION. Act 16 Geo. III.—The general direction of this navigation is nearly S. for about 9 miles, following the courſe of the Soar river, except in the laſt mile, which is a new cut; it is but little elevated; at the baſon, 300 yards from its ſouth end, it is joined by the line of the *Leiceſter* navigation and by the Charnwood-Foreſt rail-way branch belonging thereto. It commences in the *Trent* river (nearly oppoſite to the *Erewaſh* canal, and near to the *Trent* canal) near Sawley, and terminates at the Ruſhes near the town of Loughborough, which is a conſiderable place; its objects are as various as the trade of the *Trent*, and the wants of Leiceſter and other great towns; it forms alſo part of the line of communication which the *Leiceſterſhire and Northamptonſhire Union* canal is to open. On the making of the *Leiceſter* navigation, that company guaranteed the amount of the tolls on this, to amount to 3000l. annually, on condition of no more than 1s. 6d. per ton on coals or leſs than 10d. being taken by this company.

LOUTH NAVIGATION. The general direction of this navigation is nearly S.W. for 14 miles in the county of Lincoln, it is but little elevated above the ſea; its objects are the ſupply of Louth, and the adjacent country with coals, deals, &c. and the export of farming produce; it commences at the ſea-lock and ebb-gates in Titney Haven (at the mouth of the *Humber* river), and terminates at the town of Louth. From Titney Haven to the Louth river near North Cockerington $9\frac{3}{4}$ miles is level, and but little higher than low-water mark, being a new cut through a low fenny country; thence to Kiddington old mill, $2\frac{3}{4}$ miles, is 24 feet riſe; thence to the Leather-mill meadow, $\frac{3}{4}$ of a mile, is $11\frac{1}{2}$ feet riſe; thence to Louth is $\frac{3}{4}$ of a mile with 21 feet riſe. Mr. *John Grundy* made a ſurvey of this line, which was reviſed by Mr. *John Smeaton*, in 1760, the eſtimate of expence being near 15,600l. See *Smeaton*'s *Reports*, vol. i. p. 23.

LOYNE RIVER. The general direction of this river (ſometimes called the Lune) is nearly N.E. for about 7 miles in the county of Lancaſter; the tide flows through its whole length; its object is the foreign trade of Lancaſter, particularly in cabinet-maker's wares, a branch of the *Lancaſter* canal is to connect with it at Glaſſon, where a ſpacious wet-dock is intended. Lancaſter is the 56th Britiſh town with 9,030 inhabitants; this river commences in the Iriſh ſea at Sunderland point, and terminates at Lancaſter old bridge, ſome diſtance below Mr. *Rennie*'s famous aqueduct bridge over this river. It appears, that in the year 1799, 52 veſſels cleared out of this river for the Weſt Indies with 11,669 tons of goods in more than 90,000 packages, worth $2\frac{1}{2}$ millions ſterling. In October 1799, it was in contemplation, to conſtruct a ſpacious dock at Thornbuſh for large ſhips, with a canal from thence of 6 miles in length through Glaſſon-dock, and nearly up to the town of Lancaſter, to be wide and deep enough for the largeſt veſſels that trade to that place.

LYNN RIVER. The general direction of this river (ſometimes called the Lenne, the Nar, or the Setchy) is nearly S.E. by a crooked courſe of about 15 miles in the county of Norfolk; it is not greatly elevated in any part; its objects are the import of coals, deals, &c. and the export of farming produce; Lynn is the 50th Britiſh town with a population of 10,096 perſons, Narford is alſo a conſiderable town; it commences in the Great *Ouſe* river near the harbour of Lynn, and terminates at the town of Narford.

*Macclesfield and Leek.* In 1796, it was ſaid, that a canal between theſe places was in contemplation, with extenſions thereof to the Staffordſhire potteries, in all 29 miles, on which no locks were to be uſed. Macclesfield is the 61ſt Britiſh town with 8,743 inhabitants.

*Maidenhead and Iſleworth.* In the year 1770, Meſſrs. *James Brindley* and *Robert Whitworth*, were employed by the city of London, to ſurvey the line of a canal from the *Thames* river at Iſleworth, to the ſame river again below Bolter's-lock near Taplow-mill, about 1 mile above Maidenhead-bridge, and at the lower end or termination of the 3d diſtrict of the *Thames and Iſis* navigation; the length of this line is $19\frac{3}{8}$ miles with a riſe of $71\frac{1}{3}$ feet. The canal was propoſed to be 50 feet wide and 4 deep, with cuts to the *Thames* at Windſor, and near Laleham; in the firſt 5 miles 7 locks were to be built, and one in the remaining diſtance; the eſtimate of expence was 47,885l. A bill for this was brought into parliament, but the oppoſition of the landowners proved fatal to it; although, as appears, by an accurate meaſurement and ſection of the river between theſe two points made by the above engineers (ſee *Gentleman's Magazine for March* 1771), that the length of the river-navigation is $37\frac{3}{8}$ miles in this diſtance, and greatly obſtructed by ſhallows, ſome only $2\frac{1}{2}$ feet deep in dry ſeaſons. In the year 1791, this ſcheme was revived, and in 1794, Meſſrs. *Robert Whitworth* and *Robert Mylne* were employed to reviſe this line; their deſign has 12 miles of level at the upper end, and 10 of them ſtraight; the canal to be 5 feet deep. The tolls at firſt propoſed were $\frac{1}{2}$d. per ton per mile on all articles; out of this revenue, it was propoſed to improve the river navigation between Mortlake and Bolter's-lock: and to raiſe the neceſſary ſums on life annuities, ſo that after a fund was eſtabliſhed for repairs and management, the canal might at length become free for the public uſe. At Bolter's lock the *Reading and Maidenhead* canal was propoſed to join this canal, by which the navigation from London weſtward would have been amazingly ſhortened and improved.

MANCHESTER ASHTON AND OLDHAM CANAL. Acts 32, 33, 38, 40, and 45 of Geo. III.—The general direction of this canal is nearly E. for about 7 miles in the counties of Lancaſter and Cheſhire; its eaſtern end is conſiderably elevated; its objects are the ſupply of Mancheſter and Stockport with coals, cannel, ſtone, lime, &c. and forming part of the intended direct communication between Liverpool, Mancheſter, and Hull, by means of the *Huddersfield* and other canals; by means of its Duckenſield branch it communicates with the *Peak-Foreſt* canal. Mancheſter is the 2d Britiſh town with 84,020 inhabitants, Stockport is the 29th with 14,830 perſons, and Oldham the 35th with 12,024 perſons, Aſhton is alſo a conſiderable town, and the country round about is full of inhabitants. This canal begins in the *Rochdale* canal near Piccadilly ſtreet in Mancheſter, and terminates in the *Huddersfield* canal at Duckenfield bridge, in the pariſh of Aſhton underline; from Duckenfield bridge is a branch of $\frac{1}{4}$ mile in length, over an aqueduct bridge on the Tame river at Walk-mill, into Duckenfield, there to join the *Peak-Foreſt* canal. There is a branch of 1 mile to Aſhton town, another of $3\frac{3}{4}$ miles to New Mill in the pariſh of Oldham (but $2\frac{1}{2}$ miles diſtant from the town), from which laſt at Boodle-wood a branch proceeds over Water-Houſes aqueduct on the Medlock brook, to Park collieries at Stake-Leach near Hollingwood, alſo in the pariſh of Oldham; from Droylſden, a branch of 6 miles proceeds to the end of the town of Stockport in Heaton-Norris pariſh, and from this laſt, a branch of 3 miles proceeds in a N.E. direction to Beat-Bank in Denton. The line has a riſe of 152 feet between the *Rochdale* and *Huddersfield* canals. This canal is 33 feet wide at top, 15 feet at bottom, and 5 feet deep in water, except the ſummit pound which is made 6 feet deep to act as a reſervoir; the locks are 80 feet long, and the boats carry 25 tons; there are three conſiderable aqueducts at Duckenfield, Ancoats, and at Water-Houſes. This company were authoriſed by their firſt 4 acts to raiſe 170,000l., and a further ſum by the late act; amount of ſhares 100l. The line of this canal was completed between Mancheſter and Aſhton about the end of the year 1796, and in January 1797, the Stockport branch was opened; ſome of the works on this canal ſuffered by a flood in Auguſt 1799. The rates of tonnage are given in *Phillips*'s 4to. *Hiſtory*, *Appendix*, p. 21. In 1802, we were told, that the ſhares in this concern were 20l. below par.

MANCHESTER BOLTON AND BURY CANAL. Acts 31, and 41 of Geo. III.—The general direction of this canal is N.W. for about 11 miles in the county of Lancaſter; its northern end is conſiderably elevated; its objects are a communication between the great manufacturing towns of Mancheſter, Bolton, and Bury, and the carriage of coals and other articles for their ſupply, and forming part of the line of communication between Mancheſter and the *Leeds and Liverpool* canal. Mancheſter is the 2d Britiſh town with 84,020 inhabitants, Bolton is the 32d with 12,592 perſons, and Bury the 84th with 7,072 perſons. This canal commences in the *Merſey and Irwell* navigation near the junction of Medlock brook (by which it communicates with *Bridgewater*'s canal near the beginning of the *Rochdale*) at Mancheſter, and terminates at the town of Bolton, it has a branch of 4 miles in length to the *Haſlingden* canal at the town of Bury. From the *Merſey and Irwell* navigation, is a riſe of ſeveral locks to the baſon in Salford pariſh; thence for about 4 miles is level; in the next 3 miles are 12 locks, the remainder of the line is level, including the branch to Bury; the whole riſe is 187 feet. Previous to 1794, this canal was begun, and ſeveral locks were built for narrow boats, but on account of the branches connecting with wide canals which were propoſed about that time, theſe were pulled up and rebuilt, and the canal widened, including ſome expenſive deep-cutting and embanking; a want of ſkill or care appeared alſo, we are told, in the ſetting out of this canal by cutting deep through rocky ground which might have been avoided. There are two aqueduct bridges over the Irwell at Clifton-Hall and near Stocks, and one over the Leven at Long-fold, theſe are ſaid to be 20, 16, and 10 yards high; the canal was, in 1799, ſupplied by a feeder from the Irwell at Bury, but in 1802, a reſervoir and feeder alſo was found neceſſary in Radcliffe pariſh. In 1797, this canal was completed to Bolton, except the locks to connect with the *Merſey and Irwell* navigation; on the 17th of Auguſt, 1799, a great flood happened, which carried away the lower bank of this canal for 100 yards together on the ſummit-level, and another breach therein alſo happened, by which the navigation to Bolton, &c. was ſome time interrupted. This company were authoriſed by their firſt act to raiſe 97,000l., and a further ſum by the late act. The rates of tonnage are for coals, lime-ſtone, ſtone, bricks, clay, &c. 2d. per ton per mile, if they paſs a lock; but all theſe, except lime-ſtone, are to paſs on the levels for ½d. per ton per mile; and when the water runs waſte at the locks, lime-ſtone is alſo to pay only ½d. on any part; the tonnage at the entrance of the *Merſey and Irwell* navigation is alſo regulated by the firſt act. Paſſage-boats from Bolton to near Mancheſter are eſtabliſhed; but when water has been ſcarce, the paſſengers have been required to walk paſt the locks to another boat on the lower pound to avoid the waſte of lockage-water. About the year 1794, it was in contemplation to make a branch weſtward from Bolton, to connect with the *Leeds and Liverpool* canal at Red Moſs near to Wigan, and to make a grand extenſion of the Bury branch eaſtward to the *Calder and Hebble* navigation at Sowerby-bridge, paſſing the grand-ridge between Littleborough and Rippondale by a tunnel of 5 miles in length! after paſſing a ſhorter tunnel of ½ a mile at lower Lomax near Heyford. In 1796, it was propoſed to extend a branch from the baſon in Salford pariſh to Oldfield-Lane in that town; and, in 1799, it was in contemplation to build an aqueduct bridge over the Irwell, and connect this canal with *Bridgewater*'s canal, inſtead of locking down into the *Merſey and Irwell* navigation.

MARKET-WEIGHTON CANAL. Act 12 Geo. III.—The general direction of this canal is nearly N. for about 11 miles in the Eaſt Riding of Yorkſhire; it has but little elevation above the ſea; its objects are the conveyance of coals, deals, &c. to Market-Weighton and the ſurrounding country, the export of farming products, and the better drainage of the fen lands through which it paſſes; it commences in the tide-way in the *Humber* river (oppoſite to the *Trent* river) at Foſdyke-Clough, and terminates near Market-Weighton. It has a ſea-lock next the *Humber*, from whence it is level to within a ſhort diſtance of its northern end, where is a riſe of 4 or 5 locks. Mr. *John Smeaton* was conſulted on this line of canal and drainage, in 1765, at which time a branch of this canal to Pocklington was in contemplation; for the rates of tonnage, ſee *Phillips*'s 4to. *Hiſtory*, p. 270. This navigation was completed ſoon after the paſſing of the act.

*Mawgan Canal.* About the year 1775, a narrow canal was cut of 6 or 7 miles in length; from Port Mawgan near Trenance on the N.W. coaſt of Cornwall, to within 3 miles of St. Columb Major, it was intended for bringing up coals and ſea-ſand for manure, and for carrying down china-ſtone and clay, ſubſtances found in St. Dennis and St. Stephens, and uſed in the Staffordſhire potteries; but after ſeveral of the adventurers were ruined, the ſcheme was totally abandoned.

MEDINA RIVER. The direction of this navigation is ſouth, and nearly ſtraight for 4½ miles, in the Iſle of Wight in Hampſhire; the tide flows through its whole length; its object is the ſupply of Newport and the central parts of the iſland with coals and other articles; it commences at Cowes harbour (oppoſite *Southampton Water*), and terminates at Newport bridge.

MEDWAY RIVER (*lower diſtrict.*) Acts 32 and 42 of Geo. III.—The general direction of this navigation is nearly S.W. for about 27 miles by a bending courſe in the county of Kent; it is but little elevated in any part; its objects are the import of coals, deals, and other articles, and the export of Kentiſh-Rag lime-ſtone, fullers-earth, farming-produce, &c. near its northern termination, it connects with the eaſt Swale or tide-way paſſage, of about 15 miles in length ſouth of Sheppy iſland, connecting with the *Thames* near Whitſtable; and, at Nicholſon's ſhip-yard in Strood it is joined by the *Thames and Medway* canal. Chatham is the 46th Britiſh town with a population of 10,505 perſons, Maidſtone is the 66th with 8,027 perſons, and Rocheſter is the 90th with 6,817 perſons, Sheerneſs, Queenborough, and Milton, are conſiderable towns on or near this navigation, which commences in the river *Thames* at the Nore, and terminates in the upper *Medway* navigation at Maidſtone bridge. Over this river at Rocheſter, there is a ſtone bridge of 11 arches and 550 feet long. At Chatham is a very conſiderable naval arſenal. The powers of the above acts for repairing and levying of tolls, extend no further down this river than from Maidſtone to the tide-way at Aylreſford bridge.

MEDWAY RIVER (*upper diſtrict.*) The general direction of this part of the river is S.W. for about 12 miles in the county of Kent; it is not much elevated in any part; its objects are the import of coals, deals, &c. and export of lime-ſtone, fullers-earth, farming-produce, &c. beſides Maidſtone, mentioned above, Tunbridge is the only conſiderable town on this line; it commences in the lower *Medway* navigation and terminates at the town of Tunbridge. In 1802, the *Medway and Rother* canal was propoſed to connect with this river at Yalden-lees.

*Medway and Rother.* In the year 1801, a ſurvey and eſtimate was made by Mr. *Sutherland*, for a canal from the *Rother* river intended navigable branch at Small-Hithe, to the *Stour* river at Canterbury (at the S. end of the propoſed *Canterbury and Nicholas-bay* canal), with a branch thereof to the *Medway* river at Yalden-lees, through the counties of Suſſex and Kent; its objects were the ſupply of the interior country with coals and other articles, the export of timber and farming products, and forming a communication between the ſouth coaſt at *Rye-harbour* and the *Thames* river, &c. Forty-ton boats were intended to be uſed, and the canal to be 4 feet deep. The ſummit was found to be about 100 feet above the ſea, and nearly 50 miles of the line was to be upon one level.

MENAI STREIGHT. This ſtreight ſeparates Angleſea iſle from North Wales, and has nearly a N.E. direction for about 16 miles, through which the tide flows; it extends from Caernarvon bay at Abermenai Ferry to Lavan Sands; Caernarvon and Bangor are conſiderable towns on this line. In 1801, and 1802, it was in contemplation to build a caſt-iron bridge over this ſtreight at Swelly rocks near Porthacthavy Ferry not far from Bangor.

MERSEY AND IRWELL NAVIGATION. Acts 7 Geo. I. and 34 Geo. III.—The general direction of this navigation is nearly eaſt, by a crooked courſe of 50 miles in the county of Lancaſter, and ſkirting the county of Cheſter; the firſt 20 miles being by a moſt ſpacious eſtuary of the *Merſey* river; it is not greatly elevated in any part; its objects are moſt important, particularly in the immenſe trade between Liverpool and Mancheſter, and Hull, alſo by four different routes acroſs the grand-ridge; the navigations immediately connecting therewith are, at Elleſmere-port in Netherpool, where it is joined by the *Elleſmere* canal; at Weſton by the *Weaver* river; at Runcorn-Gap, and again at Mancheſter (by the Medlock Brook), by *Bridgewater*'s canal, beſides being croſſed thereby on Barton aqueduct; at Fidlers-ferry, and alſo at Sankey Brook, by the *Sankey* canal; and at Mancheſter, near the junction of Medlock Brook, by the *Mancheſter Bolton and Bury* canal: beſides which, the following commence very near to this navigation, although they do not actually lock down into it: viz. the *Leeds and Liverpool*, at the baſon in Liverpool, the *Trent and Merſey*, at Preſton Brook, and the *Rochdale*, at Mancheſter; to which alſo the *Mancheſter Aſhton and Oldham* ought to be added, although a very ſhort ſpace of two other navigations muſt be paſſed through before you can reach the Irwell therefrom. Mancheſter is the 2d Britiſh town, with a population of 84,020 perſons; Liverpool is the 4th, with 77,653 perſons; and Warrington is the 45th, with 10,567 perſons. This navigation commences in the Iriſh Sea, at Wallazy, about 3 miles below Liverpool, and terminates at the bridge between Mancheſter and Salford: but the powers of the act, as to improving the river and collecting the tolls, at firſt extended no lower than Bank-key, near Warrington, and ſince to Runcorn Gap. The winding courſe of the river has been ſhortened in ſeveral places by ſide-cuts acroſs the loops, and locks and wears have been erected in ſeveral places, the riſe in the whole length being about 70 feet; theſe rivers are ſubject to ſudden and violent floods, which have at times deſtroyed ſeveral of the navigation works; in Auguſt 1804 a new ſide-cut was completed, for ſhortening the courſe of the navigation, and avoiding the ſhallows in the river; between Warrington and Runcorn Gap it croſſes the *Sankey* canal. The famous wet-docks at Liverpool are an appendage to the *Merſey* navigation, and are indeed a part of that river, from not being excavated in ſolid ground, where houſes formerly ſtood, as they did on the ſite of the *London Docks*; but all of them, except the old Dock, which was a natural creek or pool, have been formed in the front of the town, by embankments in the river, which is here ¾ of a mile wide. At the lower or northern end of theſe docks, as we viewed them in 1797, is a large inlet or walled tide-baſon, which connects with the river, and is dry at low water, from the S.E. corner of this is the entrance of *St. George's Dock*, which was the third large dock that was made, and is nearly a parallelogram, of 250 yards long and 100 wide, its quay being 670 yards long, its gates are 25 feet high and 38 feet wide, and it coſt about 21,000 l. Paſſing ſoutherly, we next arrive at a dry baſon and wharf, called the old quay, for the flatts or veſſels belonging to the *Merſey and Irwell* company, which are about 32 in number; and ſome diſtance ſouth of this is another large inlet to a ſpacious dry baſon for ſhips: from the north end of this baſon are other gates into *St. George's Dock*, above mentioned, and ſtraight forwards is the entrance to the *Old Dock*, or the firſt that was built, and is wholly within the town; this dock forms an irregular parallelogram, of 200 yards long and about 80 yards wide, its gates being 23 feet high and 34 feet wide; it is lined with bricks, but all the other dock, baſon, and pier walls are of beautiful hewn ſtone. From the ſouth-eaſt corner of the laſt deſcribed dry-baſon is the entrance to *Salt-Houſe Dock*, which was the ſecond made, is an irregular trapezium, of 21,928 yards in area, and has 640 yards in length of quay, its gates being 23 feet high and 34 feet wide. A conſiderable diſtance ſouth of the laſt dry-baſon is an inlet to a ſmall wet-dock, which belonged to the late *duke of Bridgewater*, and is uſed by the flatts which trade between Mancheſter and Liverpool, by *Bridgewater*'s canal, theſe carry 50 tons, and 42 of them belonged to his grace. Proceeding further along the ſhore ſouthward, we arrive at another inlet and dry-baſon, from the north ſide of which is the entrance to the *King's Dock*, the fourth which was made (being finiſhed in 1788), and is a regular parallelogram, of 290 yards long and 90 wide, the gates thereof being 25 feet high and 42 feet wide. From the head, or eaſt end of the laſt dry-baſon is the entrance to the *Queen's Dock*, which was the fifth and laſt that was made, being alſo the largeſt and moſt complete of the whole, its length is 270 yards, breadth 130, its gates 25 feet high and 42 feet wide, and it coſt about 25,000 l. An attempt was made to form a dock in the ſite of the *old Dock*, as long ago as 1561, but it was not until the year 1710 that the firſt act was obtained, of which there are ſeveral, for building and regulating the preſent docks. In 1799 application was made again to parliament for powers to build two more large docks, one of them more northerly than any of thoſe we have deſcribed, and the other in front of *Salt Houſe* dock. The whole extent of theſe docks and quays will then be nearly 2 miles by the ſide of the *Merſey*! With the two dry baſons laſt deſcribed, ſeveral convenient graving-docks connect, for the building or repair of ſhips, ſome of the latter are long enough to hold three ſhips in length. The ſpace between theſe graving-docks and in front of the docks, is principally occupied by timber-yards. The draw-bridges over the entrances to ſome of theſe docks are among the largeſt and moſt complete in England: Mr. *Morris* erected and has the care of them and the docks. On the ſouth ſide of the *King's Dock* is a ſpacious warehouſe 210 feet long and 180 wide, for tobacco, of which it will contain 7000 hogſheads. The ſpring-tides here riſe 21 feet, but the neap-tides only 12 feet, on which account large ſhips cannot enter or leave theſe docks for ſome days during the loweſt tides. Fires and ſmoking of tobacco are on no account allowed on board of ſhips in theſe docks, nor lighted candles, except in proper lanthorns, and no gunpowder is allowed on board; by a ſtrict attention to which rules, no fire has ever happened in theſe docks. In the year 1797 the tolls in theſe docks amounted to upwards of 13,300 l. annually, and their yearly expences to 5,100 l. but a debt of 113,419 l. ſtill remained on them: for many of the above particulars we are indebted to *W. Moſs's Liverpool Guide*. In the year 1737

Worſley Brook was intended (and an act paſſed 10 Geo. II.) to be made navigable; and, in 1758, a branch of *Bridgewater*'s canal was intended to join at Hollin Ferry, but neither of theſe has been executed. In 1771 Mr. *James Brindley* propoſed an aqueduct-bridge over the eſtuary of the *Merſey* river, for the uſe of the intended *Liverpool and Runcorn* canal; and in 1801 Mr. *Ralph Dodd* tried to perſuade the adoption of a road-bridge over the ſame at Caſtle Rock near this place, 412 yards long, which he ſtated might be built for 47,000l. In 1799 it was ſuggeſted that a tunnel might be made under the *Merſey* at Liverpool to the oppoſite ſhore in Cheſhire, ¾ of a mile; in the ſame year it was in contemplation to build an aqueduct over the Irwell, for the uſe of the *Mancheſter Bolton and Bury* canal, to enable it to join *Bridgewater*'s canal; and in 1804 it was propoſed to bring the *Weaver* navigation to Weſton Point on this navigation, by a new ſide-cut, near that river from Frodſham, to avoid the ſhallows near the junction of the rivers. In 1758 the price of carriage on this navigation, between Liverpool and Mancheſter was 12 s. per ton, but on the completion of *Bridgewater*'s canal it fell to 6 s. per ton.

Milford Haven. This famous eſtuary and harbour for large ſhips, has nearly an eaſt courſe, for about 17 miles, in the county of Pembroke, in South Wales, commencing in St. George's channel, and terminating near Landſhipping ferry, where it is joined by the *Dougledge* and *Clelby* rivers: it has alſo creeks or branches extending to Pembroke, to near Carew Caſtle, to Creſwell, to Nangle, &c.

Monkland Canal. The general direction of this canal is nearly eaſt, for about 11½ miles in the county of Lanerk in Scotland, its eaſtern end is conſiderably elevated; its objects are the ſupply of Glaſgow, Paiſley, &c. with coals from Monkland collieries, and the export of farming products. It commences in the baſon of the branch of the *Forth and Clyde* canal, and thereby communicates with the *Clyde* river, and the *Edinburgh and Glaſgow* canal. Glaſgow is the 5th Britiſh town, with a population of 77,385 perſons. In 1803 the *Glaſgow and Saltcoats* canal was propoſed to connect with this at Glaſgow.

Monmouthshire Canal. Acts 32, 37, and 42 of Geo. III.—The general direction of this compound of canals and rail-ways is nearly north, for 17¾ miles, in the counties of Monmouth, and Brecknock in South Wales; its northern ends are very greatly elevated; its object is the export of coals, lime, and iron from the country through which it paſſes; near Pontypool it is joined by the *Brecknock and Abergavenny* canal, at Pill Gwenlly it joins to the *Sirhowy* tram-road (by means of the *Uſke* river), and at Count-y-Billa farm, and at Riſca, it joins the ſame again by different branches belonging to this company. Newport and Pontypool are conſiderable towns on this line. This canal commences in the tide-way of the *Uſke* river, near to the *Severn*, at Pill-Gwenlly, and terminates by a rail-way extenſion at Blaen-Afon iron furnaces, having alſo a principal branch of canal from the line at Crynda-Farm, near Malpas, and continued by a rail-way to Beaufort iron-works, 21 miles: from this branch are rail-way branches to Sorwy furnace, 1¼ mile, to Nant-y-glo works, 6¼ miles, and another to the Sirhowy tram-road at Riſca: from the line near Pontypool is a rail-way branch, 1 mile, to Tronſnant furnace, and another, of ½ a mile, to Blaen-Dir furnace. From the *Uſke* river to Pont-Newydd, 12½ miles, is a riſe of 447 feet by the canal, and thence to Blaen-Afon, 5¼ miles, is a riſe of 610 feet by the rail-way: from Crynda-Farm to Crumlin bridge the canal branch riſes 358 feet in 11 miles; thence for 3 miles to the rail-way bridge over Ebwy river, 3 miles, the rail-way has a riſe of 139 feet, and thence to Beaufort, 7 miles, it has a riſe of 480 feet; the Nant-y-glo branch has a riſe of 518 feet, along the ſide of Ebwy-Frach river. The locks are 60 feet long and 10 feet wide, their paddle-holes are, in ſome of them, united in the breaſt of the lock, and no ſheet-piling, or inverted arch has been made below the lower gates. Much deep-cutting and embankments have here been neceſſary, to obtain the proper ſlopes for the rail-ways and inclined planes. Mr. *Thomas Dadford* jun. is the engineer: in February 1796 the canal was completed from the *Uſke* to Pontypool, and in the ſame year the Beaufort branch was completed. This company were authoriſed by their different acts to raiſe 275,330l. in 100l. ſhares: in 1802 theſe divided 2l. 12s. 6d. each annually; it is provided, that after the profits amount to 10 per cent. and 1000l. is accumulated as a fund, the tolls are to be reduced, firſt on coals, ſo as to keep the profits within that amount. The tolls and exemptions are various, and may be conſulted in *Phillips's* 4to. *Hiſtory*, *Appendix*, p. 18 and 19, where tolls are ſpecified for cattle paſſing on the rail-ways. Nine miles of the *Sirhowy* tram-road was made by this company, who receive the tolls thereof, as alſo 110l. per annum from that company, on account of the junctions therewith: to the *Brecknock and Abergavenny* company this company paid the ſum of 3000l. for the benefit of their junction herewith, and their taking the ſame tolls only on goods paſſing on it from this canal as are charged hereon. Rail-way branches may be made to any works within 8 miles of this canal or its branches. In the year 1805 it was propoſed to continue this canal lower down the *Uſke* river, to avoid its imperfect navigation.

Montgomeryshire Canal. Act 34 Geo. III.—The general direction of this canal is nearly S.W. for 27 miles in the county of Salop and of Montgomery in North Wales; it is conſiderably elevated, particularly its ſouthern end; its objects are the ſupply of the country with lime, the export of its farming products and of coals, ſlate, free-ſtone, iron, lead, &c. from different parts near the line: it connects with the *Severn* river at Welſhpool. Welſhpool, Montgomery, and Newton are conſiderable towns on or near this canal: it commences in the Llanymynach branch of *Elleſmere* canal, at Portywain lime-works in Llanyblodwell, and uniting with the ſame again near Verniew river in Llanymynach, it terminates at Newtown: it has a cut of 3¾ miles to the *Severn* river at Welſhpool and to Guilsfield. From the *Elleſmere* branch to Newtown is a lockage of 225 feet: the Guilsfield cut is level. Mr. *Thomas Dadford* jun. is the engineer. In Auguſt 1797, 16 miles of the canal were finiſhed and opened from the *Elleſmere* branch to Garthmill near Berriew. The company were authoriſed to raiſe 92,000l.; the amount of each ſhare 100l. The water of Lledan Brook is to be taken to ſupply this canal for 24 hours weekly, from Saturday to Sunday evening; the company are bound to purchaſe certain mills, if their trade is injured by the canal: and certain creditors on turnpike tolls near the canal are alſo indemnified: the profits are not to exceed 10 per cent. but the tonnage is to be reduced, but not ſo as to bring the profits below 8 per cent.: the rates of tonnage and exemptions are various: ſee *Phillips's* 4to. *Hiſtory*, *Appendix*, p. 151 and 152. About the year 1794 the *Welſhpool and Leominſter* canal was propoſed to join this near Welſhpool.

Neath Canal. Acts 31 and 38 Geo. III.—The general direction of this canal is nearly N.W. for about 14 miles in the county of Glamorgan in South Wales; and its northern end is conſiderably elevated; its object is the export of coals, iron, lime-ſtone, &c. from the mines and works near the line; which commences in the tide-way of the *Neath* river, at Giants-grave pill in Briton's-Ferry, and terminates in the *Aberdare* rail-way branch at Abernant near Furno

Vaughan: being joined near Briton's Ferry, in the *Neath* river, by the *New Chapel* canal. Neath is the only conſiderable town on this line; near Merlin's Court is an aqueduct over the Neath river. This company were authoriſed to raiſe 35,000l.; they are authoriſed to make rail-way branches to any place within 4 miles of the line, by conſent of the land-owners. In 1798 this canal was nearly finiſhed, except about two miles at the lower end. Here is a ſingular proviſion, that the rates of warehouſe-room are to be the ſame as are charged by the *Staffordſhire and Worceſter* company at the Stourport warehouſes.

NEATH RIVER. The general direction of this navigation is nearly N. for about 4 miles in the county of Glamorgan, in South Wales: the tide flows through its whole length from Swanſea bay to Neath bridge; at Giants-grave pill near Briton's Ferry it is joined by the *Neath* canal, and near Briton's Ferry by the *New Chapel* canal; its chief objects are the ſupply and trade of Neath, and the export of the coals and iron brought down by the canals.

NEN RIVER (*lower diſtrict.*) Acts Geo. II., and 34 of Geo. III.—The general direction of this navigation is about S.W. by a very crooked courſe of nearly 75 miles in the counties of Cambridge and Huntington, and ſkirting thoſe of Lincoln and Northampton; this is by what appears to have been its ancient courſe through the Fens, beginning in the tide-way at Peter's point about 9 miles below Wiſbeach, paſſing that town, where is a bridge built of ſtone with one flat ſemi-elliptic arch of 70 feet ſpan; and turning ſouth-eaſtward by an ancient courſe (which is now rendered uſeleſs to navigators by the *Wiſbeach* canal, which joins this river at Wiſbeach and again at Outwell), to Outwell and Apwell, thence to March and Benwick, thence through Ramſey, Ugg, and Whittleſea Meers, through Horſey-bridge, and Standground ſluice to Peterborough, and thence by the regular channel of this river to the commencement of the upper *Nen* navigation at Thrapſton; in after times, a navigable courſe has been opened, for part of the waters of this river through Well-Creek, about 5 miles in length, from near Outwell-church to the Great *Ouſe* river at Salter's-Load; another from Standground (1½ mile below Peterborough) through Catt-Water and Shire Drain of about 24 miles in length to the *Nen* river again at Gunthorpe-ſluice (about 6½ miles below Wiſbeach), this laſt having a cut of about 2 miles in length from it into the old *Welland* river near Crowland; in 1490, biſhop Moreton cut a new ſtraight courſe 40 feet wide and 13 miles long, called Moreton's Leam, for a part of theſe waters, from Standground ſluice (about 2 miles below Peterborough) to near Guyhirne, and thence 3 miles by an old channel to the *Nen* again near Wiſbeach; alſo, at Benwick this river is joined by the Benwick-Meere branch, of the Great *Ouſe* river. The above will ſerve to give ſome idea of the principal lines of navigation belonging to this river through this ſurprizing country; but as all the rivers, and all drains almoſt in the fens are embanked on both ſides, and owing to the deficiency of fall are almoſt ſtill water, there are a great number of ſmaller navigable branches interſecting and croſſing each other in all directions, ſo that it would be in vain for us to attempt to deſcribe them. The powers of the commiſſioners under the above acts, extend only about 30 miles downwards to Peterborough bridge; the navigations through the fens are preſerved by the fen corporation in maintaining their drainage works. In 1721, Mr. *Nathaniel Kinderley* recommended the cutting of a new channel or outfall for this river (as has been ſince ſucceſſively practiſed by him on the *Dee* river at Cheſter) from the mouth of Shire-drain at Gunthorpe-ſluice ſtraight along the N.W. ſhore for 2 miles to Peter's point; and the work was begun, but the miſtaken notions of the people of Wiſbeach then, and till lately, prevented its completion: we are glad, however, to hear, that the ſame is likely now to be ſoon accompliſhed, and a greater depth of water obtained in this river, and through Croſs-keys waſh to Lynn and Boſton deeps. By the act for *Wiſbeach* canal 34 Geo. III., all veſſels paſſing out of or into that canal from the *Nen* are to pay 3d. per ton, out of which 100l. is to be paid annually to the commiſſioners under the above acts for improving this river above Peterborough, and the remainder is to be applied to deepening and improving the ſame between the *Wiſbeach* canal at Outwell and the *Ouſe* river at Salters-Load. Boats which have paid the above toll are to paſs toll free at Salters Load, and Standground ſluices on this river.

NEN RIVER, (*upper diſtrict.*) The general direction of this navigation is nearly S.W. for about 23 miles, in Northamptonſhire: it is not greatly elevated; its objects are the ſupply of Northampton and the ſurrounding country with coals, deals, &c. and the export of agricultural productions. The communication between Lynn, London, Liverpool, Mancheſter, &c. which it now effects is alſo important. Northampton is the 85th Britiſh town with a population of 7,020 perſons, Wellingborough, Thrapſton, and Higham-Ferrers, are alſo conſiderable towns on or near this river; it commences in the lower *Nen* navigation at Thrapſton, and terminates at the rail-way branch of the *Grand Junction* canal at the town of Northampton, where alſo it is to be joined by the *Leiceſterſhire and Northamptonſhire Union* canal. This navigation has been improved by a great number of ſide-cuts and pound-locks by the ſide of the river in different places; it was completed and opened to Northampton on the 7th of Auguſt 1761. About the year 1793, the *Leiceſter and London* canal was propoſed to croſs this river near Wellingborough.

*Newark and Bottesford.* In the year 1793, a canal was intended from the *Dean* river at Newark to the long level of the *Grantham* canal at Stainwith, paſſing near the town of Bottesford. In the *Grantham*, act 33 Geo. III., the tolls are provided that are to be paid at the junction of theſe canals, if this is ever executed.

*Newcaſtle and Carliſle.* In the year 1795, Mr *William Chapman* ſurveyed the line for a canal from the *Tyne* river at Newcaſtle to the *Eden* river at Carliſle, through Durham, Northumberland, and Cumberland, croſſing the grand-ridge for a connection between the eaſt and weſt ſeas; and having a collateral branch of narrow canal and inclined planes to the elevated mining diſtricts of Weardale and Teeſdale foreſts, &c. the eſtimate being 355,067l. On the rejection or ſuſpenſion of this ſcheme, a canal from *Newcaſtle to Haydon-bridge* was propoſed as below.

*Newcaſtle and Haydon-Bridge.* In 1796, and again in March 1802, it was in contemplation to make a canal nearly following the courſe of the Tyne river, between Newcaſtle and Haydon, in Northumberland and Durham.

*Newcaſtle and Maryport.* Some years previous to 1801, a canal was projected between the tide-way in Maryport harbour and the *Tyne* river at Newcaſtle, croſſing the grand ridge, and paſſing between the two ſeas, though Cumberland and Durham counties: a bill for the ſame was brought into parliament, but rejected, owing to the oppoſition that the favourers of another ſcheme gave to it: in 1801, the ſcheme was again revived, but nothing effectual has been done towards its adoption.

NEWCASTLE (*under-line*) CANAL. Act 35 Geo. III.—The general direction of this navigation is nearly weſt, by a very bending courſe of 3 miles, in the county of Stafford: its objects are the bringing of Caldon lime for manure, and the export of coals and farming products: it is conſiderably elevated. Newcaſtle is a conſiderable town, and its neighbourhood very populous. This canal commences in the *Trent and Merſey* canal (near to the end of the Caldon branch) at Quinton's Wood, in Stoke, and terminates in the *Newcaſtle under-line Junction*, at the ſouth-eaſt corner of Newcaſtle town. It was completed in a ſhort time after the act was obtained, the company being authoriſed to raiſe 10,000 l.; the amount of ſhares therein is only 50 l. each. The rates of tonnage and wharfage are on coals, lime-ſtone, and iron-ſtone 1½d. per ton per mile, on all other goods 2d. per ton per mile, but for leſs than a ton of any article in a boat 6d. Between December and the 1ſt of April this company may take flood waters from the Trent river.

NEWCASTLE (*under-line*) JUNCTION CANAL. Act 38 Geo. III.—The general direction of this canal is about N.W. for a ſhort diſtance, in two detached parts, in the county of Stafford: its weſtern ends are much elevated, and terminate near the grand ridge on its eaſtern ſide: its object is the export of coals and agricultural produce. Newcaſtle is a conſiderable town on its line. It commences in the *Newcaſtle-under-line* canal, at the S. E. corner of that town, and terminates its eaſtern part in the canal of Sir *Nigel Bowyer Greſley*, near the S. W. corner of the town; its weſtern part commences in *Greſley*'s canal above mentioned, near Apedale, and extends to Partridge-Neſt collieries, with a branch to Bignel-End collieries. This company were authoriſed to raiſe 12,000 l., the amount of their ſhares being 50l. only: proviſion is made in the act for inclined-planes and water-levels, or rail-ways, with engines to raiſe water or draw trams, &c. in caſe any of theſe ſhould be found more eligible than a canal with locks, in any part. Pleaſure boats to pay for 6 tons if they paſs any lock. In 1796, the *Commercial* canal, for 40 ton boats, between the *Aſhby* and *Cheſter* canals, was propoſed to occupy or paſs through the line of this canal, when enlarged.

NEW CHAPEL CANAL. The general direction of this canal is eaſt, by a bending courſe of about 3½ miles, in the county of Glamorgan, in South Wales; the greater part of it is cut through a moraſs, but little above the level of the tide-way in which it commences, in the river *Neath*, near Briton's Ferry (near the entrance of the *Neath* canal), and terminates at New Chapel, near Swanſey: it is the ſole property of the owner of the land, and for whoſe improvement, by draining and otherwiſe, it was principally undertaken.

*Newport and Stone.* In June 1797, it was propoſed to make a canal from the *Donnington Wood* canal (the marquis of *Stafford*'s) at Pave-lane, near Newport, by Eccleſhall, to the *Trent and Merſey* canal, near Stone, a courſe of about 18 miles, in the counties of Salop and Stafford, croſſing the grand-ridge; a branch was propoſed to Market-Drayton: its object was the opening of a direct communication between Shrewſbury, and other places on or near the upper parts of the *Severn*, and the *Trent and Merſey* canal, for ſupplying the intermediate country with coals and lime, &c. In 1765, the *Tern-bridge and Winsford* canal was propoſed, and intended to paſs through nearly the ſame ground as the middle parts of this canal; as was alſo the *Sandbach* on an other occaſion.

NEWRY CANAL (*Ireland*). This canal, from the tide-way at Fadham point to the town of Newry, was completed under the direction of Mr. *Golborne*, in February 1761, after being two years in hand, by which brigs of 80 or 100 tons burthen can come up to Newry; it was intended to extend this to the *Blackwater* navigation, for conveying the Dungannon and Drumglaſs coals to Dublin; and the Iriſh parliament, between 1753 and 1771, granted different ſums of the public money for this purpoſe, amounting to 11,434l. but the work then was far from being completed.

NITH RIVER. The courſe of this river (ſometimes called the Nid) is nearly north for about 9 miles, between Dumfries and Kirkcudbright counties, in Scotland; the tide flows through its whole length, and its object is the ſupply of Dumfries, (the 79th Britiſh town, with 7,288 perſons); it commences in Solway Firth, and terminates at Dumfries bridge, which is of ſtone, with 13 arches. In 1760, Mr. *John Smeaton* was conſulted on the encroachments by jetties of ſtakes and ſtones for gaining land, that had been made at Cargin, Lagal, and Netherwood, on this river, and recommended the removal of ſome of theſe works at the projecting points of the river.

NOTTINGHAM CANAL. Act Geo. III.—The general direction of this canal is nearly N. W. by a crooked courſe of about 15 miles, in the county of Nottingham; it is not very greatly elevated: its objects are the export of coals from the ſeveral mines near it, and of farming products, importing lime, deals, &c. Nottingham is the 17th Britiſh town, with a population of 28,861 perſons. This canal commences in the river *Trent*, near Nottingham (oppoſite to the junction of the *Grantham* canal), and terminates in the *Comford* canal, near Langley bridge, and near to the termination of the *Erewaſh* canal: near to its ſouthern termination it is joined by the *Trent* canal or ſide-cut (from the *Trent and Merſey* canal). A reſervoir is made near Amſworth for the ſupply of this canal, and has a ſelf-regulating ſluice which lets out near 3000 cubic feet of water per hour for certain mills and the *Erewaſh* canal. In 1802, this canal was completed.

NUTBROOK CANAL. Act 33 Geo. III.—The general direction of this canal is nearly N. W. for 5 miles, in the county of Derby: it is not greatly elevated: its object is the export of coals from the mines near the line; which commences in the *Erewaſh* canal, near Stanton, and terminates at Shipley colliery; it has a branch to Weſt Hallam collieries. Sir Henry Hunloke and Edward Miller Mundy, eſq. were authoriſed to raiſe 19,500 l. between themſelves, in 100 l. ſhares; their profits hereon are not to exceed 8 per cent.; and proprietors of adjoining lands may make ſide branches thereto: the particulars of the tonnage rates are very long, including ſome regulations with the *Erewaſh* company, &c. See *Philips's* 4to. *Hiſtory*, *Appendix*, p. 104 and 105.

OAKHAM CANAL. Acts 33 and 40 Geo. III.—The general direction of this canal is about S. E., by a crooked courſe of 15 miles, in the counties of Leiceſter and Rutland: its ſouthern end is conſiderably elevated, croſſing the Tilton and Burley branch from the grand-ridge: its objects are the ſupply of Oakham, and the country through which it paſſes, with coals, deals, &c., and the export of agricultural products. Oakham and Melton-Mowbray are conſiderable towns on this line, which commences in the *Leiceſter and Melton-Mowbray* navigation, at Melton-Mowbray, and terminates at the town of Oakham. From the *Leiceſter and Melton-Mowbray* navigation to Edmondthorpe, 8½ miles, it has a riſe of 126 feet; the remaining 6½ miles to Oakham are level, and it is fed by a reſervoir for flood-waters in Langham, and another in Saxby. The engineers were Mr. *William Jeſſop* and Mr. C. *Stavely*, jun. In November 1800, this canal was opened from Melton-Mowbray to Saxby bridge, and in January 1803, the whole was completed. This company was authoriſed to raiſe 86,000 l. in 100l. ſhares. The rates of tonnage and wharfage, with the exceptions therefrom, may be ſeen in *Phillips's* 4to. *Hiſtory*, *Appendix*, p. 106 and 107; but to which the laſt act made an addition, and the *Leiceſter and Melton-Mowbray* act, 40 Geo. III., alſo contains ſome regulations affecting the tolls at the entrance to this canal. Earl Winchelſea is to be paid 15l. annually, in lieu of his cuſtomary dues on coals ſold in Oakham town.

OUSE RIVER (*Lewes lower Navigation*). Act 31 Geo. III.—The general direction of this navigation is nearly north, for near 9 miles, in the county of Suſſex: the tide flows through its whole length: its objects are the import of coals, deals, &c. and the export of farming products. Lewes is a conſiderable town on this navigation; which commences in the Engliſh channel, at Newhaven harbour, and terminates in the upper *Ouſe* navigation, at Lewes bridge: the meadows, called Lewes and Laughton Levels, near this river, were ſubject to be overflowed, and it is part of the object of the above act to embank the river and its tributary ſtreams, and to erect proper ſluices, and cut drains for the improvement thereof; part of the money for which draining purpoſes, is to be raiſed by the commiſſioners of ſewers, under the act of 23 Hen. VIII., by different rates per acre on each of the five diſtricts into which the levels are by this act divided, but the works are to be performed by the truſtees appointed by this act, who, in 1802, completed the ſtraightening and deepening of the courſe of the river, ſo that the tides flowed higher and ebbed lower than before at Lewes bridge, and to which place veſſels drawing 4 feet of water can now come up. The tolls on articles navigated on any part of this river are to be, for manures not exceeding 2d. per ton, for road-materials 3d., and for all other goods 4d. per ton, empty boats to paſs toll free; theſe tolls are not to be lowered (except road-materials to 2d.), ſo long as 6,000l. of the money borrowed on the credit of theſe tolls and the acre-taxes, remain undiſcharged; the tolls are intended hereafter to be ſo reduced, that one-third of the whole expences of maintaining the navigation and drainage works ſhall be paid by the acre-taxes, and two-thirds by the tolls on the river; the acre-tax is, however, to make up the deficiency, if the above tolls are inadequate; lands below Newhaven bridge are not to be taxed, but to maintain their own banks. In the year 1762, Mr. *John Smeaton* was conſulted about improving the navigation and drainage of this river. About the year 1793, a new pier was built to protect the harbour of Newhaven, and the entrance of this river; in 1802, it was propoſed to add a new groin thereto to the weſtward, for the further ſecurity of veſſels; and, in 1804, it was in contemplation, by large ſtones from the neighbouring cliff, to extend a rough unwalled pier much further out into the ſea, for the ſecurity of veſſels on this coaſt.

OUSE RIVER. (*Lewes upper Navigation*). Act 30 Geo. III.—The general direction of this navigation is nearly north-weſt, by a bending courſe of about 22 miles, in the county of Suſſex: it is not much elevated above the level of the ſea: its objects are the import of coals, deals, &c. and carrying chalk and manures to the lands, and the export of their agricultural products. Lewes and Cuckfield are conſiderable towns on this line; it commences in the lower *Ouſe* navigation, at Lewes bridge, and extends to Hammer bridge, near Slaugham, with a branch to Offham chalk-pit, in Hamſay; the depth of water in every part is to be made 3½ feet: the boats to be 50 feet long and 12⅓ feet wide, and are not to paſs locks with leſs than 10 tons of lading. This company were authoriſed to raiſe 25,000l. in 100l. ſhares, and the works were not to commence until 10,000l. of this was ſubſcribed, and 10 per cent. thereon actually paid: it is to that public ſpirited and worthy nobleman lord *Sheffield* that the country are in a principal degree indebted for bringing about this uſeful meaſure. From Lewes bridge to Barcome mill there was an old and imperfect navigation for ſmall boats; on this part of the line, the rates of tonnage are to be, on manures, road-materials, timber, grain, &c. ½d. per ton per mile, and on all other goods 1d. per ton per mile; on the remainder or new part of the line, manures, &c. as above, are to pay 1d. and other goods 1½d. per ton per mile. Empty boats to pay 1s. for paſſing each lock, and pleaſure boats 3d. below and 6d. above Freſhfield bridge for paſſing locks. Between Old Eye, in South Malling, and Land-Port, no toll is to be taken, on goods carried no farther. Branches may be made to any place within 2000 yards of this river, on which the powers of the commiſſioners of ſewers (23 Hen. VIII.) ſtill continue. In 1801, it was propoſed to make an extenſion of the *Surry iron rail-way* to join this navigation at Linfield. In 1802, the navigation was not completed up to Hammer bridge; but, in the following year, it was ſaid that a new act for further powers for that purpoſe was in contemplation.

OUSE (*great*) RIVER. The general direction of this river is nearly S. W., by a crooked courſe of about 84 miles, in the counties of Norfolk, Cambridge, Huntington, and Bedford, and ſkirting Suffolk for a ſhort diſtance: this courſe through the fens being from the tide-way in Lynn-deeps, (2 miles below that town), paſt Lynn, Telney, Salter's Load, Denver-ſluice, Rebeck, Little-port-chair, Ely, Harrimere, Hermitage-ſluice, Erith, and thence by the regular channel of this river to Bedford. Soon after the year 1630 (in conſequence of a law of ſewers of the 13th of January, 6 Charles I.) the old Bedford river, (a ſtraight cut, of 21 miles long and 70 feet wide), was made, between Hermitage-ſluices and Salter's-Load, for conveying part of the waters of this river; and in 1652, the ſcheme of Sir *Cornelius Vermuyden* for another navigable cut nearly parallel to the laſt was carried into effect, (under the authority of an act of Cromwell, 1649, confirmed afterwards by 15 Charles II. eſtabliſhing the fen corporation); this laſt, called the New Bedford river, is 20 miles long and 100 feet wide, from Hermitage ſluices to Denver's ſluice, both theſe new cuts falling into the great *Ouſe* river again, at Salter's-Load and Denver's ſluice (which are within about a mile of each other, and 17 miles from Lynn); beſides theſe, part of the waters of this river make their way by a navigable cut of about 12 miles in length, from Hermitage into the *Nen* river at Benwick. In 1725, Mr. *Thomas Badeſlade* mentioned, and, in 1751, Mr. *Nathaniel Kinderley* ſtrongly recommended, another ſhorter cut between Eaubrink and Lynn, for ſtraightening the courſe of this river, for which the acts of the 35, 36, and 45 of Geo. III. have been paſſed, called the Eaubrink cut, and on which Mr. *Robert Mylne*, ſir *Thomas Hyde Page*, and captain *Joſeph Huddart* are employed as engineers; this cut was, in September 1804, marked out, and is intended to be 296 feet wide at the eaſt end, 204 feet at the weſt end, and about 2¾ miles in length, making eaſy bends into the river at each end, with banks on each ſide, at a diſtance from the cut, 6 feet higher than the ordinary tides, of 15 feet riſe, with an embankment and ſluice acroſs the old channel, above the eaſt entrance of the new one; which important works ere long, we hope, will be completed. Near the harbour of Lynn this river is joined by the *Lynn* river; at Salter's-Load, by a branch of the *Nen* navigation (called Well Creek); between Salter's-Load and Denver's ſluice it is joined by *Stoke* river; at Rebeck the little *Ouſe* joins; at Prick-willow the *Lark* river joins; near Barkway chapel the *Soham-Lode;* at Harrimere, the *Cam* river joins; and at Temsford the *Ivel* river alſo joins: the whole of the rivers and large drains in the theſe fens being embanked and nearly level; there are many others of them navigable for ſhort diſtances beſides the above. Lynn is the 50th Britiſh town, with a population of 10,096 perſons: Downham, Ely, St. Ives, Huntingdon, St. Neots, are alſo conſiderable towns on this line. Denvers dam and ſluice, with 5 eyes or arches, was built acroſs the great *Ouſe* river, juſt above the entrance of the new Bedford-river, in the year 1651; in 1713, the water having undermined three of the arches, they were carried away, and were not rebuilt again until 1746. At Willington and others of the mills in the upper parts of this navigation, there is a kind of ſelf-acting ſluices in uſe, which fall down to let the water paſs freely over them, when the water in a flood riſes above a certain height; the locks on this part of the navigation are of wood, the towing-path has ſtiles near it, and is frequently interrupted as before mentioned. In November 1790 a dry dock in Lynn, connecting with this river, was opened, being the firſt work of the kind which had been erected for the accommodation of that port. About the year 1780, a cut, of about $1\frac{1}{2}$ mile in length, was made from this river, in Willington, to the turnpike road in Cople, where a houſe and conveniencies for a wharf were built (now the Dog ale-houſe) at a great expence; but the conſent of the proprietor of the *Ouſe* navigation, who holds it under a particular grant from the crown, could not afterwards be obtained for this cut being uſed as a navigation. In 1785, and again in 1802, the *London Lynn and Norwich* canal was propoſed to join this river at Lynn. And in 1792, the *Leiceſter and London* was propoſed to join and croſs it at Bedford.

Ouse (*Little*) River. This river (often called the Brandon) has its courſe nearly eaſt, for about 20 miles, between the counties of Norfolk and Suffolk: it is not greatly elevated in any part: its objects are the import of coals, deals, and the export of agricultural products. Brandon and Thetford are conſiderable towns on this river, which commences in the great *Ouſe*, at Rebeck, and terminates at the town of Thetford, to which place boats with 14 or 15 chaldrons of coals in each could come up in the year 1649. The lower part of this river for ſeveral miles is embanked on both ſides, through the fens. In the year 1789, this navigation was propoſed to be joined at Hiſs near Wilton by the intended *Biſhopſtortford and Wilton* canal.

Ouse River (*York*). Act 23 Henry VIII.—The general direction of this river is nearly north-weſt for about 48 miles, between the Eaſt, Weſt, and North Ridings and Ainſty Liberty in Yorkſhire; it is not very greatly elevated in any part; its objects are the trade and ſupply of the city of York, and of the immenſely populous and trading diſtricts in the Weſt Riding. At Goole-Bridge it is joined by the *Don* river; at Armyn, by the *Ayre and Calder* navigation; at Barnby, by the *Derwent* river; at Selby, by a cut of the *Ayre and Calder* navigation; near Cawood, by the *Wharfe* river; and at York, by the *Foſs* river. York is the 23d Britiſh town, with a population of 16,145 perſons. Howden, Snaith, Selby, and Cawood are alſo conſiderable places on or near this river; which commences in the *Humber* river at Trent-fall (the junction of the *Trent* river) to the *Yore* river at Linton. Ships of 150 or 160 tons burthen come up to Armyn, and ſmaller maſted veſſels to York city. By a licence of Richard II. the corporation of York are required to maintain certain bridges on the upper part of this river. In the year 1795, a large wooden draw-bridge, of 13 openings, was built by Mr. *William Jeſſop* over this river at Selby, under an act of parliament. In 1769, the *Selby and Leeds* canal was propoſed to connect with this river at Selby.

Oxford Canal. Acts 9, 15, 26, 34, and 39 of Geo. III.—The general direction of this canal is nearly north, by a very crooked courſe in its northern half, of 91 miles, in the counties of Oxford, Warwick, and Northampton; it croſſes the grand-ridge by a tunnel, and its northern part ſkirts along near to it on the weſtern ſide for many miles; its objects were a communication between the midland canals and the metropolis, (but a much nearer route is now opened by the *Grand-Junction* canal,) the ſupply of the northern parts of Oxfordſhire with coals, the export of farming products, &c. At Woolvercot is a cut of about $\frac{1}{4}$ mile (belonging to the duke of Marlborough), by which a communication with the *Thames and Iſis* navigation at Godſtow is effected. At Napton the *Warwick and Napton* canal joins this; and at Braunſton the *Grand-Junction* canal joins. Coventry is the 24th Britiſh town, with a population of 16,034 perſons; and Oxford is the 38th, with 11,694 perſons. Woodſtock, Deddington, Banbury, Southam, Daventry, and Rugby are alſo conſiderable towns on or near to this line of canal; which commences in the *Thames and Iſis* navigation at Badcock's Garden on the weſt ſide of Oxford city, and terminates in the *Coventry* canal at Longford. At Hillmorton and at Napton are ſhort cuts, of about $\frac{1}{2}$ a mile each, to the ſteam-engines belonging to this company. From the *Thames and Iſis* at Oxford to Banbury, $27\frac{1}{4}$ miles, is a riſe of 118 feet by 18 locks (including 2 weir-locks and an entrance lock from the Iſis); thence to Claydon, $7\frac{1}{4}$ miles, is a riſe of $77\frac{1}{3}$ feet by 12 locks; thence (through the Fenny-Compton tunnel) the ſummit pound continues to Marſton-doles wharf $10\frac{3}{4}$ miles, and level; thence to Napton on the hill 2 miles, is a fall of $55\frac{1}{4}$ feet by 9 locks; thence to Hillmorton, $16\frac{3}{4}$ miles (in which the *Warwick and Napton* and the *Grand-Junction* join), is level; thence in $\frac{1}{2}$ a mile is a fall of 19 feet by 3 locks; thence to the *Coventry* canal at Longford, $26\frac{1}{2}$ miles, is level. The two ſhort cuts to the engines, and that at Woolvercot, are level. This canal is 28 feet wide at top, 16 feet at bottom, and $4\frac{1}{2}$ feet deep, except the ſummit pound, which is made 6 feet deep in order to act as a reſervoir; the locks are $74\frac{3}{4}$ feet long, and 7 feet wide. At the toll-houſe near Longford is a ſtop-lock, to prevent the *Coventry* canal in dry ſeaſons, from lowering the water in the long pound on this; from which long pound an engine at Hillmorton pumps water into the Braunſton pound, by means of a feeder; and out of this laſt pound by means of a ſough. Another engine at Napton pumps into the ſummit pound, which is alſo fed by three reſervoirs. The number of ſtone and brick bridges on this line is 188, and of wooden, ſwing, draw, and foot bridges 66. The Fenny-Compton tunnel is 1188 yards long, $9\frac{1}{3}$ feet wide, and $15\frac{1}{2}$ feet high. At Newbold is a tunnel 125 yards long, made under the church-yard and ſtreet, 16 feet high, and $12\frac{1}{2}$ feet wide, with a towing-path through it. At Wolfhamcote, alſo, there is a ſhort tunnel. At Pedlars-Bridge near Brinklow is an aqueduct bridge of 12 arches, of 22 feet ſpan each. At Coſford on the Swift river, and at Clifton on the Avon, are others of 2 arches each; at Wolfhamcote, Adderbury, and Hampton-Gay, are other ſmaller aqueducts. Mr. *James Brindley* made the ſurvey for this canal in September 1768; in Auguſt 1769 he began the work near Longford; and in 1775 it was completed from thence to the Napton locks; when 122,300l. having been expended, the works ſtood ſtill for want of money until 5th April 1786, when they were reſumed; on the 31ſt of March 1778 the line was opened northward to Banbury; and on the 1ſt of January 1790 the whole was completed. Mr. *James Barnes* was employed to execute ſome of the digging of this part. This company have been authoriſed to raiſe, by their different acts, 330,000l.; the amount of their ſhares is 100l. each. In January 1800 theſe are ſaid to have ſold for 194l., and in 1802 for 275l. each; the *Grand-Junction* company being bound to make up the tolls hereon to 10,000l. annually, (if the works are kept in order) on condition of this company taking only certain tolls on goods paſſing to or from that canal, (ſee *Phillips*'s 4to. *Hiſt. Apend.* p. 32.) and agreeing to widen about 35 miles of their canal and lock[illegible] large boats may paſs north of [illegible]mton, whenever the *Grand-Junction* company ſhall re[illegible] and the *Coventry* company. The rates or tonnage are [illegible] complicated; they will be found in *Cary's Inland Navigation*, pages 59, 74, and 80. For parcels under [illegible] cwt. the company are to fix ſpecific rates in their printed tonnage tables. Coals from the inland pits were not allowed, by the firſt act above, to come nearer to London than Oxford; but by the 3d act, this was extended to Reading and the *Kennet* navigation; and in the year 1800 this company offered 2s. per ton as a premium on coals carried certain diſtances from their canal into Berkſhire, &c. The narrow barges uſed on this canal ſeldom venture down the *Thames* to London, but goods are generally ſhifted at Oxford into the Thames-barges. About the year 1792 the *Stratford and Croperdy* canal was propoſed to join this at Croperdy; and, at the ſame time, a canal from *Hampton-Gay to Iſleworth* was intended, to join this at Hampton-Gay.

PARNEL'S CANAL. This ſhort canal, or rather water-level, has nearly a north direction for about ½ a mile in the valley north of St. Auſtle, (near the ſouth coaſt of Cornwall) one mile above that town; it commences within an immenſe excavation of great depth, and open to day, which has, by the work of ages, been made in a rocky hill abounding with tin ore. It is tunnelled through the ſolid rock for 200 yards or more, on a level to the ſurface of the hill, and proceeds forwards thereon to the top of an inclined plane, of about 50 feet fall, where the boats are raiſed up an end by a windlaſs to ſhoot out the ore, as already deſcribed on *St. Columb* canal. At the bottom of the plane the ore is loaded into carts, to be carted to the ſtamping-mills. Small ſquare-headed boats are uſed, and four or five of them are linked together to be ſhoved through the tunnel, by means of chains which are fixed along its ſides for that purpoſe, and they are afterwards towed along the canal to the head of the plane. This canal, tunnel, and plane, were made at the expence of Mr. *Parnel*, who owns the mine, about the year 1770, before which the ore was drawn up to the top edge of the pit or mine, and carted from thence.

PARRET RIVER. The courſe of this river is nearly ſouth-eaſt for about 5 miles, in the county of Somerſet; it is not greatly elevated; its objects are the import of coals, and the export of agricultural products. Langport is the only conſiderable town near this navigation. It commences in the *Tone and Parret* navigation at Borough-Chapel, and terminates in the *Ivelcheſter and Langport* navigation, a little below Langport.

PEAK-FOREST CANAL. Acts 34, 40, and 45 of Geo. III.—The general direction of this canal and rail-way is nearly ſouth-eaſt for 21 miles, in the counties of Cheſter and Derby; its ſouthern end is very conſiderably elevated, and terminates on, or very near to, the Grand-Ridge; its principal object is the export of the Peak-Foreſt lime, and of coals from the neighbourhood of this canal. Aſhton-under-line, Stockport, and Chapel-le-Frith are conſiderable towns on or near this line; which commences in the *Mancheſter Aſhton and Oldham* canal, at Duckenfield, (near to the termination of the *Huddersfield* canal,) and the canal terminates at the baſon and lime-kilns in Chapel-Milton, whence a rail-way proceeds to Loads-knowl lime-ſtone quarries in the Peak. The line of the canal is 15 miles in length, and of the rail-way 6 miles; there is a cut of ½ a mile to Whaley-Bridge, and a rail-way branch of 1½ mile to Marple. Over the Merſey river, near Marple, is a grand aqueduct bridge of 3 arches, each 60 feet ſpan and 78 feet high, the whole height of the ſtructure being near 100 feet, which was built in the year 1799. (This bridge we have before, by miſtake, when treating of Aqueducts, mentioned as being on the *Mancheſter Aſhton and Oldham* canal.) Mr. *Benjamin Outram* was the engineer, and the works were completed on the 1ſt of May 1800. The company were authoriſed to raiſe, by the firſt act, 150,000l., each ſhare being 100l., which in 1802 bore a premium of 10 per cent. It has been ſaid, on ſeveral occaſions, that this canal and rail-way were completed at 10 per cent. under the original eſtimate, and that the 2d act authoriſed the company to raiſe any unlimited ſum that they might want, in which there certainly were miſtakes, becauſe the act of the laſt ſeſſions was for raiſing a further ſum of money. For the rates of tonnage and wharfage, ſee *Phillips*'s 4to. *Hiſtory, App.* p. 155. Mine-waters may be uſed for the ſupply of this canal, but only the flood-waters of the rivers.

PENTLAND FIRTH. This ſtreight has nearly a weſt direction between Caithneſs county, at the north-eaſtern extremity of Scotland, and the Orkney iſlands. This, though a rocky and dangerous paſſage, is much frequented by ſhips, on account of being the firſt paſſage which preſents itſelf for ſhips in going northward, between the Eaſt and Weſt Seas, or German Ocean and Iriſh Sea. The *Inverneſs and Fort-William* canal, now cutting a great way ſouth of this for the uſe of ſhips, is expected much to leſſen the uſe of this firth. Serabſter road-ſtead, on the ſide of this firth, is a harbour much frequented by ſhips in blowing weather. Thurſo harbour in Caithneſs, on the ſouthern ſide of this firth, has a pier now building, and its harbour improving, under an act of 42 of Geo. III.

POLBROCK CANAL. Act 37 of Geo. III.—The general direction of this canal is nearly ſouth-eaſt for about 5 miles in Cornwall, near its north-weſt coaſt; it is not greatly elevated; its objects are the import of coals, and the export of ſtone and agricultural products. Bodmin is a conſiderable town near it. It commences at Guinea-port, near Wade-bridge, in the *Camel* river, and terminates at Dunmeer Bridge and Stoney Lane, in the pariſh of Bodmin, having a collateral cut of ½ a mile to Ruther Bridge, in the ſame pariſh. At Guinea port and at Stoney-Lane Bridge large and convenient baſons and warehouſes are intended. Mr. *John Rennie* and Mr. *Murray* are the engineers. This company may raiſe 18,000l. in 50l. ſhares. A feeder from the Camel river and any ſprings within 2000 yards may alſo be taken for this canal.

POOLE HARBOUR. This ſpacious inlet or harbour has nearly a weſt courſe for about 9 miles, in the county of Dorſet; the tide flows into every part of its various branches and inlets, and round Brankſea iſland, which is in the middle of it; its object, beſides the general trade and ſupply of the neighbourhood, is the export of a fine potter's clay found near to Corfe Caſtle, in the iſle of Purbeck, and paving-ſtones and free-ſtone from thence. Poole, Wareham, and Corfe Caſtle are conſiderable towns near this harbour, which commences in Studland Bay and terminates at Wareham Bridge: a branch proceeds about 2¼ miles north to Creek-Moor. In 1797 ſeveral improvements in this harbour were in contemplation.

PORTSMOUTH HARBOUR. This inlet or harbour has nearly a north courſe, for about 5¼ miles, in Hampſhire; the tide flows through it, and the depth of water in moſt parts of it is ſufficient for the large ſhips of the Britiſh navy. Portſmouth is the 13th Britiſh town, with a population of 32,166 perſons; Goſport and Fareham are alſo conſiderable towns adjoining it. It commences at Spithead, in the Channel, between Hampſhire and the Iſle of Wight, and terminates at Fareham Bridge, having alſo a branch to Coſham, and a communication therefrom to Langſtone and Chicheſter harbours. On the ſhores of this harbour there are immenſe buildings and works, for the uſe and ſecurity of the royal navy. In 1805 ſeveral conſiderable additions were making to theſe works, and a bridge between Goſport and Haſlar hoſpital, which Mr. Robert Forbes built ſome years ago, is intended to be taken down, having proved injurious to the harbour.

*Portſmouth and Croydon Canal.* In the years 1802 and 1803, a canal was in contemplation from *Portſmouth Harbour* to the *Croydon Canal* at that town, paſſing Havant, Chicheſter, Arundel, Horſham, Ryegate, and Merſtham, of which that able engineer, Mr. *John Rennie*, prepared plans and an eſtimate; but the oppoſition of the land-owners, and favourers of a rail-way ſcheme from *Portſmouth to London* procured its rejection in parliament. The ſummit-level of this canal was to be 36 miles in length, at about 220 feet above the level of the ſea: this was to be fed by ſeveral reſervoirs in or near Horſham Foreſt, containing in the whole 500 acres, and 340,000,000 cubic feet of water. This level was to penetrate the Chalk-Hills north-eaſt of Merſtham, by a tunnel 4¼ miles long, and 350 feet below the top of thoſe hills. The eſtimated expence was 721,000l., and 800,000l. in 100l. ſhares was propoſed to be raiſed; the expected revenue was eſtimated at 100,000l. per annum. While this line was in contemplation, there was an attempt made by Mr. *Ralph Dodd* to draw the public attention to a different line of canal, (which Mr. *John Phillips* laid claim to, as being one of the fanciful ones which he has drawn in the map to his 4to. Hiſtory, 1791,) from *Portſmouth Harbour*, through *Southampton Water* and the *Itchen River*, to Wincheſter; thence to Alresford, near to Alton and Farnham, and to the Wey river at Godalming: from near Weſtley on that river, the propoſed line of the *Grand Surrey* canal was to be followed to Deptford and the *Thames* river. The eſtimate mentioned on this occaſion was 348,735l.

*Portſmouth and London Rail-way.* In 1803, Mr. *William Jeſſop* was employed to ſurvey the line of a rail-way from Portſmouth town to the weſt end of Stamford-Street, near Blackfriars-Bridge, London; on the utility of which, and the *Portſmouth and Croydon* canal above, opinions were for ſome time divided: in the end, neither of them was adopted. The eſtimated expence of this work was 400,000l.

Ramsden's Canal. Act 14 Geo. III.—The general direction of this canal is nearly ſouth-weſt for about 8 miles, in the Weſt Riding of Yorkſhire; it is not very greatly elevated; its objects at firſt were the ſupply and trade of Huddersfield town, but it will ſhortly have conſiderable importance as part of the ſhorteſt line of navigation between Hull and Mancheſter and Liverpool. Huddersfield is the 81ſt Britiſh town, with a population of 7268 perſons. This canal commences in the *Calder and Hebble* navigation, at Cooper's Bridge, and terminates in the *Huddersfield* canal, at King's Mill near Huddersfield; it has a riſe of 56¾ feet by 9 locks. Sir *John Ramſden*, who is the ſole proprietor of this canal and of Huddersfield town, in 1766 employed Mr. *James Brindley* to plan this canal; and, after his death, it was begun and quickly completed by Mr. *Luke Holt*. At Huddersfield ſpacious warehouſes are built by the ſide of this canal, to which goods intended to be there lodged may be carried toll-free along the part of this canal from the *Huddersfield* canal; that company guaranteeing the tolls on this not to be leſſened thereby. On the whole length or any part of this canal, coals, flags, ſlates, ſtones, lime ſtones, and lime, are to pay a toll of 3d. per ton, and all other goods 1s. 6d. per ton, except dung and manures, which are to paſs free. The proprietors' profits are never to exceed 6 per cent. upon the monies laid out thereon.

*Reading and Maidenhead.* In 1770, a canal was propoſed from the *Thames* river, at Bolter's Lock near Taplow-Hill, (at the weſtern termination of the *Maidenhead and Iſleworth* propoſed canal,) to the *Thames* again, at Sunning near Reading and to the *Kennet* river, on which Mr. *James Brindley* was conſulted by the city of London, the diſtance being near 15 miles by the canal, and by the river above 30 miles, between the ſame places; a barge of 120 tons being 3 days (and often in dry times as many weeks) in performing the voyage, at an expence equal to 50l.; while, by this canal, it was calculated that a barge might at all times, except froſt, perform it in 6 hours, at 4l. 7s. expence, including ½d. per ton to the truſtees as a toll. This canal was at firſt propoſed to commence at Monkey iſland in the *Thames*, which is 2 miles below Maidenhead-Bridge. No private property was to be allowed in this canal, but the money was propoſed to be raiſed by life annuities, out of which, and the tolls, the river navigation was to be improved between Bolter's Lock and Sunning, without any new tolls being charged thereon; and when a ſufficient fund was accumulated for repairs and management, the tolls were to ceaſe, and the canal be entirely free.

Ribble River. The direction of this river is nearly eaſt for about 12 miles in the county of Lancaſter; the tide flows through its whole length: its objects are the ſupply and trade of Preſton town, and the export of coals brought down by the *Douglas* river, which joins it near Haſketh. Preſton is the 37th Britiſh town, with a population of 11,887 perſons. This river commences with a very wide eſtuary or mouth in the Iriſh Sea, but grows very ſhallow, ſo as to be fordable at low-water, and terminates at the bridge at Preſton, near to the aqueduct bridge, on which the *Lancaſter* canal croſſes this river. In September laſt, (1805) it was propoſed to apply for an act for placing buoys, and otherwiſe improving the navigation of this river.

Ripon Canal. Act 7 Geo. III.—The general direction of this canal is nearly N.W. by a bending courſe of about 7 miles in the Weſt, and ſkirting the North Riding of Yorkſhire: its objects are the ſupply of Ripon, and the export of agricultural products, ſtone, &c. It is conſiderably elevated; Borough-bridge, Ripon, and Aldborough, are conſiderable towns on or near this canal, which commences in the *Yore* river at Milby, near Borough-bridge, and terminates at Ripon.

Rochdale Canal. Acts 34, 40, and 44 of Geo. III.—The general direction of this canal is nearly N. E. by a bending courſe of 31½ miles in the counties of Lancaſter and York; it croſſes the grand-ridge by a deep-cutting: its general objects are the communication between Liverpool and Mancheſter, with Halifax, Wakefield, Hull, &c. the export of coals, paving-ſtones, &c. At Piccadilly ſtreet in Mancheſter it is joined by the *Mancheſter Aſhton and Oldham* canal. Mancheſter is the 2d Britiſh town, with a population of 84,020 perſons; Huddersfield is the 44th, with 10,671 perſons; Spotland the 55th, with 9,031 perſons; and Halifax the 58th, with 8,886 perſons. This canal commences in *Bridgewater*'s canal at Caſtle-Field in Mancheſter, and terminates in the *Calder and Hebble* navigation at the baſon, wharf and warehouſes at Sowerby bridge: to near Hollingwood chapel there is a branch of $\frac{3}{4}$ of a mile, and another of $\frac{1}{2}$ a mile to School-lane in Caſtleton near Rochdale. From *Bridgewater*'s canal to Piccadilly wharf, and the *Mancheſter Aſhton and Oldham* canal, 1$\frac{1}{8}$ mile, has a riſe of 75$\frac{1}{2}$ feet; thence to the Hollingwood branch, 4$\frac{3}{8}$ miles, has a riſe of 81 feet; thence to Failſworth brook, 2$\frac{3}{4}$ miles, is level; thence to the Rochdale branch, 4$\frac{1}{4}$ miles, has a riſe of 120 feet; thence to Clay-hall, 2$\frac{1}{4}$ miles, has a riſe of 62 feet; thence along the ſummit-pound and through the deep-cutting to Travis-mill, 5$\frac{3}{8}$, is level; thence to the *Calder and Hebble* navigation, 11$\frac{3}{8}$ miles, has a fall of 275 feet; the Hollingwood and Rochdale branches are level. From near Rochdale to Sowerby-Bridge there are 49 locks, (which are of the ſame width and length as *Bridgewater*'s at Runcorn:) more than 60 bridges and 8 aqueducts and large culverts. At Hallin's mill is a tunnel of 70 yards in length, 17 feet high and 21 feet wide, with a towing-path through it. At Dean-Head, between Littleborough and Todmerden, is a ſtupendous deep-cutting in hard rock, ſome of it 50 feet deep. A very large reſervoir is made on the weſt ſide of the ſummit, and an 100 horſe ſteam-engine is uſed to pump the water up to the ſummit-pound. On a bog on Blackſtone edge are two other large reſervoirs, one of them 14 yards deep. Gauges for regulating the ſtreams of the Roch, Irwell and Irk rivers, ſo that only their ſurplus flood-waters are taken for the ſupply of this canal, were contrived and erected by Mr. *John Rennie*, the engineer. Steam-engines within 20 yards of the canal are allowed to condenſe by its water. On the 28th of December 1798, the eaſt end of the line from Sowerby bridge to Rochdale was completed; on 18th September 1802, it was continued to Lomeſide wharf; and on 21ſt December 1804, the whole line was completed and opened to Mancheſter. This company are to pay a compenſation to the duke of *Bridgewater* for his warehouſes at Caſtle-Field, and to the *Calder and Hebble* company for their warehouſes at Sowerby bridge. This company were authoriſed by their firſt act to raiſe 391,000l. (the amount of ſhares 100l. each) and by the laſt act they were authoriſed to raiſe a large ſum in addition. The rates of tonnage and wharfage, and the exemptions in the firſt act, will be found in *Phillips*'s 4to. *Hiſtory*, pages 157 and 159, to 161; alſo, by the ſecond act, certain additions were made to theſe tolls. Cuts or rails-ways may be made to any preſent or future coal-mines near the line. In 1791 a branch from this canal was propoſed from near Todmarden (104 feet below the ſummit-level) to 2 miles beyond Colne, having a tunnel thereon of 1$\frac{1}{4}$ mile in length, about 3 miles N. E. of Todmarden.

ROTHER RIVER. The general direction of this river is nearly N.W. by a crooked courſe of about 19 miles in the counties of Suſſex and Kent; it is but little elevated above the ſea in any part: its objects are the import of coals, &c. and the export of oak-timber and agricultural products: near Rye harbour, oppoſite to Pleydon-heights, it is joined by the *Shorncliff and Rye* canal. Rye, Winchelſea, Appledore, and Tenterden are conſiderable towns on or near to this navigation; which commences in the tide-way of the Engliſh Channel near Rye old harbour, and terminates at Roberts-bridge; it has a branch of about 2$\frac{1}{2}$ miles to Winchelſea bridge, and ſome other navigable branches in the level fens which ſurround Oxney Iſland, and adjoin Romney-marſh. The harbour of Rye near the mouth of this river, from its tendency to choak up, formerly employed the abilities of captain *John Perry*, Mr. *John Smeaton*, and other eminent engineers; and under the acts of 29 Geo. I. and 1, 37, and 41 of Geo. III. ſeveral works have been conſtructed. Previous to the reign of Edward I., it is ſaid, that the *Rother* vented its waters into the ſea at old Romney harbour, about which time a new channel was cut for it to ſea at old Rye-harbour, which for a long time ſcoured itſelf out, and was deep enough for the uſe of large veſſels, the tide flowing 24 miles up the river; but ſea-ſluices being afterwards erected in improper ſituations, and embankments made, by which (before 1698) the channel became too ſhallow for ſhips, and in 1719 it was rendered quite uſeleſs for navigation; ſoon after 1721, the ſluices above mentioned were removed, but the evil was become ſo irreparable, that captain *Perry* adviſed, and effected the cutting of, an entire new channel of about a mile in length, 150 feet wide at top, and 70 at bottom, ſince called the new harbour (from the ſea, near 2 miles weſt of the old harbour) into the channel of the Winchelſea river, and through that to the *Rother* and old harbour at Rye; this new canal (finiſhed 14th July 1762) had about its middle part, a ſtone ſluice of two openings, one for the paſſage of veſſels, and the tide near high-water, 40 feet wide, ſhut by double gates pointing to Landward, and another of 30 feet wide, cloſed by 5 draw-gates, to be occaſionally opened for ſcowering the mouth of the new channel or harbour, at which there were two ſtone piers erected at 120 feet apart. The upland and tide waters continued to have their courſe to ſea by the old channel or harbour, and Mr. *Smeaton* who was conſulted in 1763, confidently foretold, that unleſs the old channel was cloſed up near Rye, below the entrance to the new one, ſo as to turn the upland waters through the new harbour, it would be in time quite filted up, as happened ſo completely previous to 1797, that an act then paſſed repealing all the former acts relating to this new harbour, and the tonnage which coaſting veſſels had paid ſince it was eſtabliſhed, on paſſing or entering the ſame, was transferred to Ramſgate harbour, near *Stour* river, into which ſuch ſhips are able to run for ſhelter, in caſe of a ſtorm coming on. The new Rye-harbour was in conſequence blocked up, by a bank below the Winchelſea river, over which the new road between Winchelſea and Rye now paſſes: ſoon after this, the *Rev. Daniel Pape* revived the ideas of Meſſrs. *Perry* and *Smeaton*, with regard to the entrance of the old harbour, and by the aſſiſtance of Mr. *Southerden*, cut a new channel, or ſea vent, for the river, about $\frac{1}{4}$ of a mile weſt of the old harbour's mouth, and being about $\frac{1}{4}$ of a mile in length, before it interſected the old harbour: at this place Mr. *Pape* conſtructed a dam of ſtraw, faggots, and gravel, which effectually blocked up the old harbour's entrance, and forced the tide to enter and return, and the river waters to vent themſelves through his new cut (as Mr. *Smeaton* had in vain before recommended to be done with Mr. *Perry*'s new cut.) After which, Mr. *Sutherland* conſtructed a pier-head on the eaſt ſide, and two jetties on the weſt ſide of the preſent entrance to the harbour, which is now ſaid (ſee *Tranſactions of the Society of Arts*, vol. xxii. p. 249.) to be capable of admitting ſhips of 250 and 300 tons burthen at ſpring tides, which here riſe 23 feet, and the neap tides 14 feet. In December 1799, it was propoſed to improve the navigation of this river between Rye and Robertſbridge, to extend the navigation of the Winchelſea branch to Siddleſcombe, and to make a new navigable branch from Blackwall to Smallhithe near Tenterden. In April 1802, this laſt branch was propoſed to be joined by the intended *Medway and Rother* canal.

*Sandbach Canal.* In the year 1793, a canal was propoſed to be made from the *Severn* river below Shrewſbury to the *Trent and Merſey* canal at Sandbach, with a cut to Betley, and another to join the *Cheſter* canal near Nantwich. The *Ternbridge and Winsford*, and the *Newport and Stone* canals, have at different times been propoſed through parts of the ſame tract of country.

SANKEY CANAL. Acts 28 of Geo. II. and 1 of Geo. III. —The general direction of this canal is nearly N.W. by ſo very bending a courſe, that it exceeds a ſemicircle; its length is 12½ miles in the county of Lancaſter; it is not very greatly elevated in any part: its objects are the export of coals and ſlates, and the ſupply and trade of St. Hellens and Newton, and the copper, glaſs, and other works near them; near Sankey bridge it connects with, and is croſſed by the ſide-cut made in 1804 for avoiding the ſhallows in the *Merſey* between Warrington and Runcorn. Warrington is the 45th Britiſh town, with a population of 10,567 perſons; Newton and St. Hellens are alſo conſiderable towns near, or on this canal; which commences in the *Merſey and Irwell* navigation at Fiddlers-ferry, and terminates near Sutton-heath collieries. Near the mouth of Sankey brook it has a ſhort cut of about ⅛ of a mile, forming another communication with the *Merſey* river; there is a branch of about ⅜ of a mile to Penny bridge, and another of ¼ of a mile to Gerrard's bridge. From the *Merſey* to Sutton heath is a riſe of 78 feet, by 8 ſix-feet locks, and 2 double locks of 15 feet riſe each. The higheſt ſpring tides riſe within about a foot of the level of the water at the firſt lock. Veſſels deeply laden were generally unable to paſs into or out of the *Merſey* for two or three days of neap tides before the *Merſey* cut above mentioned was made. This canal is 48 feet wide and $5\frac{7}{12}$ feet deep in water; it has 18 bridges, all of which are wooden ſwing-bridges, even for the great turnpike road between Mancheſter and Liverpool. Between St. Hellens and Sutton-heath there is a ſhort tunnel; the canal is fed by a feeder from Sankey brook, and there are proviſions for enabling the farmers near this canal to irrigate therefrom, between the 10th of October and 1ſt of May annually. Mr. *John Eyes* was the engineer, and has the honour of completing this, *the firſt Engliſh canal*, that was attempted; it was opened between the *Merſey* and Gerrard's bridge in the year 1760. The ſum of money to be raiſed for the purpoſes of this canal is not limited in the acts, as is done in all modern canal acts. The proprietors are authoriſed to take 12d. per ton on all goods which are navigated on any part of their canal, except limeſtone, road-materials and manures, which are toll free: 63 cubical feet of coal, cannel, charcoal, coke, or cinders, are to be rated as a ton, and a buſhel of coals is to be heaped meaſure in a veſſel 19½ inches diameter outſide, and capable of containing one buſhel and one quart of water Wincheſter meaſure. In June 1797, a loaded barge was rowed 20 miles on this canal by a machine worked by a ſteam-engine on board of the barge, as before mentioned.

*Selby and Leeds.* In 1769, Mr. *James Brindley* ſurveyed the line of a canal from the *Ouſe* river at Selby to the *Leeds and Liverpool* canal (near to the termination of the *Ayre and Calder* navigation) at Leeds: it was propoſed to paſs Thorp dam, near to Thorp hall, Hambleton, Hillham, Burton-Salmon, (where a tunnel was intended,) near Fairburn, Newton, the Fire engines, and croſs the Ayre river, by Thwait mill, Hunſlet, and ſo on to Leeds, a courſe of 23 miles in length: the oppoſition of the *Ayre and Calder* company, who were in the reign of William III. indulged with very high rates of tonnage, and ſome other perſons, proved fatal to this ſcheme when it came before parliament.

SEVERN RIVER. Acts 19 Hen. VII., 23 Hen. VIII. and 12 and 43 of Geo. III.—The general direction of this noble river is nearly north, by a crooked and bending courſe of about 174 miles, ſkirting the counties of Somerſet, Glouceſter, Glamorgan, Monmouth, and Hereford, and through the counties of Worceſter, Salop, and Montgommery: commencing in the tide-way in the *Briſtol Channel*, at Flat-Holm light-houſe, and terminating in the *Montgommery* canal at Welſhpool. Its northern end is conſiderably elevated: the trade of various kinds is very immenſe on this important river, and the many navigations which connect therewith. At the lower layer it is joined by the *Glamorganſhire* canal and *Cardiff and Merthyr-Tydvill* rail-way; at New Amſterdam by the *Sirhowy* rail-way; at Naſh by the *Uſke* river; (not far from its junction with *Monmouthſhire* canal, and a branch of *Sirhowy* rail-way); at King's Road by the Bath *Avon* river; at Beachley by the *Wye* river; at Berkley-Pill, Hotch-Crib, and at Glouceſter by the *Glouceſter and Berkley* canal; at Framiload by the *Stroudwater* river and canal; at Glouceſter, on each ſide of Alney Iſle, and at Laſſington by the *Hereford and Glouceſter*; at Fletcher's leap with *Coombe-hill* canal; at Tewkſbury by the Stratford *Avon*; at Diglis by the *Worceſter and Birmingham*; at Hawford by the *Droitwich* canal: at Stourport by the *Stour* river and *Staffordſhire and Worceſterſhire*, and the *Leominſter* canals; at Coal-port and at Loads-croft near Coalbrooke dale, by the *Shropſhire* canal; and at Shrewſbury by the *Shrewſbury* and *Elleſmere* canals. Briſtol is the 7th Britiſh town, with a population of 68,645 perſons; Shrewſbury the 36th, with 14,739 perſons; Worceſter the 40th, with 11,352 perſons; and Glouceſter the 72d, with 7,579 perſons; Cardiff, Newport, Chepſtow, Thornbury, Berkley, Newnham, Tewkſbury, Upton, Bewdley, Kidderminſter, Bridge-North, Much-Wenlock and Welſhpool, are alſo conſiderable towns near to, or upon this river. The falls which this river has in particular parts have been mentioned in a preceding part of this article, as alſo a valuable experiment of 11 years continuance on the floods, droughts, and froſts which affected its navigation; which is unaſſiſted by any locks, ſide-cuts, weirs, or other erections, except the towing-paths, which Mr. *William Reynolds* begun between Coal port and Coalbrook-dale, in conſequence of an act, 12 of Geo. III., ſince renewed, for making a towing-path between Coalbrook-dale and Bewdley bridge, and levying certain tolls on goods navigated on that part of the river for defraying the expences of ſuch path, which has been ſince completed; and in 43 of Geo. III. a ſimilar act for making a towing-path from Bewdley bridge to the *Worceſter and Birmingham* canal at Diglis below Worceſter, which is, we believe, alſo completed. The trade on the middle parts of this river is carried on by two ſorts of veſſels, viz. barges 40 to 60 feet long with a ſingle maſt and ſquare ſail, carrying from 20 to 40 tons, and trows with a main and top-maſt about 80 feet high, and ſquare ſails; theſe are 160 feet long and 16 to 20 feet in width, and carry 40 to 80 tons. Some years ago, Mr. *John Wilkinſon* introduced ſome barges made of caſt iron plates for navigating this river. In the 16 Geo. III. an act was obtained for erecting a caſt-iron bridge of one arch (the firſt ever erected; ſee our article BRIDGE) over this river at Broſely or Madeley wood near Coalbrook-dale. The high floods, in 1795, carried away a narrow and inconvenient ſtone bridge that was at Buildwas, about 2 miles above Madeley wood, and in 1796, a new caſt-iron bridge was erected in its ſtead, as before deſcribed: by an act of the 17 Geo. III. a new ſtone bridge was erected over this river at Glouceſter, by which the navigation there was much improved. At Shrewſbury the very long and curving loop of the river is tunnelled through by a ſmall arch for conveying water to ſeveral mills at its junction again with the river. In the year 1765, the *Ternbridge and Windsford* canal was propoſed to join this river at Ternbridge; in 1786 the *Stourbridge and Worceſter* was propoſed to join at Diglis; in 1793, the *Sandbach*, and another canal in oppoſition to the *Elleſmere* (called, in ſome maps, the Eaſtern Grand Trunk,) were propoſed to join this river below Shrewſbury. In 1795, the *Welſhpool and Leominſter* was intended to join at Welſhpool; in 1797, the *Briſtol and Glouceſter* was propoſed to join, both at Glouceſter and at Worceſter, to this river; and, in 1801, the *Severn and Wye* rail-way was propoſed to join this river at Lidney.

*Severn and Wye Rail-way*. In the year 1801, a line of rail-way was projected from the *Severn* river at Lidney, acroſs the foreſt of Dean, connecting with the collieries thereon, and extending to the *Wye* river at Engliſh Bichnor, we believe. At a meeting, on the 14th of June, 1802, the ſouthern part of this deſign was relinquiſhed, and the *Dean-Foreſt* rail-way was propoſed in lieu of the other part.

SHANNON RIVER, (*Ireland*). The general direction of this famous river is nearly N.E. by a crooked courſe of more than 100 miles, between the counties of Kerry, Limerick, Clare, Tipperary, Galway, King's county, Meath, Longford, Elphin, and Leitrim in Ireland. It commences in the Atlantic Ocean, at Loop-head, and terminates at Carrick on the Shannon, which is 65 miles above Banagher. It is joined by the *Grand Canal* at Tormanbury, and it alſo is joined by the *Limerick* canal. Limerick, Kilalow, Clonfort, Leitrim, Carr, Longford, Roſcommon, Athlone, Portumny, Nenagh, Aſkeaton, Clare-Abbey, &c. are conſiderable towns on or near to this river. About the year 1750, the improvement of the navigation on this river was attempted, by the erection of ſluices with gates on its ſtream, for damming up and making flaſhes for the boats to paſs through with. The Iriſh parliament, at different periods, between 1753 and 1771, granted ſeveral ſums of the public money, amounting to 39,160l. for the improvement of this navigation. It was not until about March 1804, that the upper part of the navigation on this river was completed.

SHORNCLIFF AND RYE CANAL. Defence act 43 Geo. III.—The general direction of this ſingular canal is nearly S.W. by a bending courſe of about 18 miles, through Romney marſh in the counties of Kent and Suſſex. It is ſo nearly level with the ſea as to require no locks but the tide-locks at its extremities. Its objects, beſides aiding the defence of this part of our coaſt, is the import of coals and ſea-beach for road-making; the export of farming products, and improving the drainage of the marſh: Hythe, Rye, Appledore, and Folkſtone are conſiderable towns near this line; which commences in the tide-way of the Engliſh channel at Shorncliff battery near Hythe, and terminates in the tide-way of the *Rother* river oppoſite Pleydon Heights near Rye. This canal is of width and depth ſufficient for veſſels of 200 tons to navigate; it has a military road by its ſide, and is flanked throughout with batteries of great ſtrength. This canal was projected by the royal military engineers, in the autumn of 1804; and in June laſt (1805) 3000 men were ſaid to be employed thereon, and before now it is, we believe, completed.

SHREWSBURY CANAL. Act 33 Geo. III.—The general direction of this canal is nearly E. by a crooked courſe of $17\frac{1}{2}$ miles in length, in the county of Salop: its eaſtern end is greatly elevated, and at no great diſtance from the grand-ridge on its weſtern ſide; its objects are the export of coals from its eaſtern end, for the ſupply of Shrewſbury, and ſupplying the ſame with farming products, and the country with lime and manures; at Wombridge it is joined by the *Ketley* canal. Shrewſbury is the 36th Britiſh town, with 14,739 perſons. This canal commences in Caſtle Foregate baſon, at the town of Shrewſbury, (near to the *Elleſmere* canal, with which it may be joined by mutual conſent,) and terminates in the *Shropſhire* canal above Wrockandire-wood plane near Oaken-gates. From Shrewſbury to Langdon, near 12 miles, is level; thence to near Wombridge, $4\frac{1}{4}$ miles, is a riſe of 79 feet, by locks; thence is an inclined plane of 75 feet riſe, and near $\frac{1}{8}$ of a mile in length, to the *Ketley* canal; thence (along the part which was purchaſed by this company of Mr. *William Reynolds* for 840l. being half of what it coſt) to the *Shropſhire* canal, $1\frac{1}{8}$ mile, is level. The locks on this canal are contrived in two diviſions by doors, which draw up, out of a receſs formed for them below the locks, ſo that a long narrow canal boat of the uſual conſtruction, or two or four ſmaller and narrow flat-bottomed boats adapted to the inclined-plane, can paſs the ſame without unneceſſary waſte of water. Near Atcham is a tunnel of 970 yards in length, and 10 feet wide, which has a towing-path 3 feet wide through it, conſtructed of wood, and ſupported on bearers from the wall, ſo as not to diminiſh the water-way. At Long is a long embankment and an aqueduct bridge, or rather trough of caſt iron, over the Tern river, 62 yards long, and 16 feet above the level meadows, of which we have already given a deſcription in this article; at Roddington are another embankment and a common aqueduct bridge, 21 feet above the ſurface of the Roden river, over which the canal paſſes, and at Pimley there are another embankment and aqueduct of leſs height and width than the former ones. At Wombridge there is a double *inclined-plane* of 223 yards in length, and 75 feet perpendicular riſe, up one of which, empty or partly laden boats are drawn by the aid of a ſteam-engine, or by the deſcent of a loaded boat at the ſame time on the other, as we have before deſcribed. Mr. *Thomas Telford* and Mr. *William Reynolds* were the engineers employed or conſulted on the conſtruction of the works on this canal. In March 1796, the Long aqueduct was finiſhed; and in February 1797, the whole line was completed and opened. This company was authoriſed to raiſe 70,000l. the amount of each ſhare being 100l. The rate of tonnage is 2d. per ton per mile on all goods, and 1d. per ton for paſſing the inclined-plane; manures, except lime, being exempt on the pounds, but not to paſs the locks when the water is $\frac{1}{2}$ an inch under the lock-weirs. The profits of this concern are not to exceed 8 per cent. on the capital, after which the toll on boats for paſſing the plane is to be firſt lowered or taken off. The act in providing for the purchaſe of $1\frac{1}{8}$ mile of Mr. *Reynolds*'s Ketley canal as above, requires him to pay 2d. per ton per mile afterwards for navigating the ſame, as above. Leſs than 8 tons in a boat, except in returning, is to be paid for as ſuch.

SHROPSHIRE CANAL. Act 28 Geo. III.—The general direction of this canal, or rather ſyſtem of water-levels and inclined-planes, is nearly north, about $7\frac{3}{4}$ miles, in the county of Salop: its northern end is greatly elevated, and at no great diſtance from the grand-ridge on its weſtern ſide; its objects are the export of coals and iron, and the carrying up of lime-ſtone. It communicates near Oaken-Gates with the *Shrewſbury* canal; it has no large town near it. It commences in the *Severn* river at Coal-Port, (a new town eſtabliſhed by the late excellent Mr. *William Reynolds*, whoſe rapidly increaſing manufactories in the year 1800 employed 400 perſons,) and terminates in the *Donnington-Wood* canal at Donnington-Wood. It has a branch from Southall Bank, which proceeds to Brierly Hill near Coalbrook-dale ($2\frac{3}{4}$ miles), and thence is continued by an inclined plane and railway below, to the *Severn* at Loads-Croft, near the Broſley iron bridge. There is alſo a ſhort rail-way branch to Horſe-Hay iron works. At the *Severn* river at Coal Port (formerly called Sheep-waſh Meadow) there is a flood-lock, which riſes ſufficient to clear the higheſt floods in the river, parallel to which the canal proceeds on a level, $\frac{3}{4}$ of a mile, to near Hay, where is an inclined plane of 350 yards long and 207 feet perpendicular riſe ; thence to near Windmill Farm, $1\frac{1}{4}$ mile, is level canal, where is another inclined plane of 600 yards in length, and 126 feet perpendicular riſe ; thence to the Brierly branch at Southall-Bank, $2\frac{1}{4}$ miles, is level canal ; thence to the *Shrewſbury* canal at Oaken-Gates, 3 miles, is level ; thence to near Wrockardine-Wood, $1\frac{1}{4}$ mile, is alſo level : at this place is a third inclined plane, of 320 yards in length and 120 feet perpendicular fall : thence to the *Donnington-Wood* canal, 100 yards, is level. The boats are ſhallow, and carry 5 tons. There are no locks on this canal, which is ſupplied with water by two ſmall reſervoirs which lie above the canal, and two others below its level, the water therefrom being pumped up by the ſteam engines belonging to the inclined planes ; the waters which are lifted from the mines contribute alſo materially to the ſupply of the different lengths of canal. The three great inclined planes at Hay, Windmill, and Wrockardine, have each a ſhort inclined plane deſcending from their tops into the upper canals, up which the boats, on a proper wheeled carriage, are dragged by the ſteam-engines, working the wheels, drums, and ropes, and are, by the aſcent of another boat, or the operation of a brake-wheel, let eaſily down the long plane, as has been particularly deſcribed already in this article. At Brierly-Hill the crates or iron baſkets of lime-ſtone were drawn up, and the coals in boxes were let down, through perpendicular ſhafts, 120 feet deep, by ropes winding on a drum above ; but ſeveral years ago this plan was laid aſide, and an inclined plane, ſimilar to the three others above, except that it has no ſteam-engine, has been adopted, as before mentioned. Six boats have been paſſed down, and as many taken up, the Windmill plane of 600 yards long, in the courſe of a ſingle hour ; the ſteam-engine and 3 men only being employed. It is ſaid that only 3d. is charged for letting down a loaded boat, and empty ones are returned gratis. Mr. *William Reynolds* and Mr. *Henry Williams* were the engineers ; and the works were completed, and the canal opened in the year 1792 ; it is ſaid to have coſt only 47,500l. The rate of tonnage is 2d. per ton per mile on all kinds of goods. In the year 1797, the tolls produced a net profit of 6 per cent. on the capital.

SIRHOWY RAIL-WAY. Act 42 Geo. III. (for *Monmouthſhire canal*).—The general direction of this rail-way or tram-road is nearly N. W., for about 28 miles, in the counties of Monmouth, and of Brecknock in South Wales : its northern end is much elevated : its object is the export of coals and iron from the rich mineral country through which it paſſes : at Court-y-billa farm, and at Riſca, it is joined by rail-way branches of the *Monmouthſhire* canal. Newport is a conſiderable town near its ſouthern extremity : it commences at the *Uſke* river, near Pill-Gwenlly (oppoſite the commencement of the *Monmouthſhire* canal), and terminates at Trevil lime-ſtone quarries, in the pariſh of Llanguinider ; and it has a branch to Rumney union iron works ; the line paſſing through Sirhowy and Tredegar iron works, and through Tredegar park ; it was ſaid alſo, that a branch of the rail-way was to be conducted from near Tredegar park to the meadows near the *Severn* river, where a new ſea-port town, to be called New Amſterdam, was laid out and begun. This company were authoriſed to raiſe 45,000l., the amount of their ſhares being 100l., and they have engaged to pay 110l. annually to the *Monmouthſhire* canal company, on condition of their conſtructing the firſt 9 miles of this tram-road neareſt to *Uſke ;* ſir *Charles Morgan* is to make 1 mile in length of the ſame through his park at Tredegar, and receive the tolls thereon ; and Meſſrs. Samuel Homfray, Richard Fothergil, Matthew Monkhouſe, William Thompſon, William Forman, and other iron-maſters, are alſo to conſtruct particular parts of this concern. It was provided, that if theſe ſeveral parties failed to execute their ſeveral parts of the line, previous to Michaelmas day 1803, that the act, as far as relates hereto, ſhould be void. A new turnpike road is made by the ſide of this rail-way for 21 miles : the aſcent of the rail-way is ſo eaſy and regular that one horſe can draw 10 tons down the line, and return with the empty trams. A new town was laid out and begun at Tredegar new iron works, near Sirhowee.

SLEAFORD NAVIGATION. Act 32 Geo. III.—The general direction of this navigation is nearly weſt, for about 12 miles, in the county of Lincoln ; it is but little elevated above the ſea, the greater part of it being embanked on both ſides through level fens : its objects are the ſupply of Sleaford and the ſurrounding country with coals, deals, &c., and the export of farming produce. Tatterſhall and Sleaford are conſiderable towns near this navigation. It commences in the old *Witham* river at Chapel-Hill (not far from the commencement of *Horncaſtle* canal), and terminates at the caſtle-cauſeway near Sleaford. The locks are 60 feet long, and 15 feet wide in the clear ; the width of the canal is 30 feet at top, 18 at bottom, and four feet deep, except the ſummit pound from Haverholm mill to Sleaford, which is to be 5 feet deep, to make a reſerve of water, which is to be ſupplied from the fens above the navigation in New Sleaford. This company was authoriſed to raiſe 23,000 l., the amount of ſhares 100l. each. The tolls are various for different parts of the line. See *Phillips*'s 4to. *Hiſtory*, *Appendix*, p 26. Lime, manures, and road-materials pay only half the rates of other articles. The profits of this concern are limited to 8 per cent. and after 1000l. is accumulated as a fund for contingencies, the tolls are to be lowered. This company are to join with the *Horncaſtle* canal company, in the expence of improving the old *Witham* river between Lincoln high bridge and the *Foſs-dyke* navigation at Brayford-Meer ; in conſequence of which only half the uſual tolls on the old *Witham* are to be taken, on goods paſſing to or from theſe navigations.

SOHAM LODE. The direction of this navigable cut or lode is nearly S. E., for about 4 miles, and is embanked through the level fens in Cambridgeſhire : it commences in the great *Ouſe* river, near Barway chapel, and after paſſing through Soham-Meer, terminates at the town of Soham : its objects are the ſupply of coals, &c. to Soham, and the export of farming products.

SOMERSETSHIRE COAL CANAL. Acts 34, 36, and 42 Geo. III.—The general direction of this canal is nearly S. W., for about 10 miles, beſides a principal branch of $7\frac{1}{2}$ miles nearly parallel thereto, in the county of Somerſet : its weſtern ends are conſiderably elevated : its object is the export of coals from the mines north of Mendip hills. Bath is the 12th Britiſh town, with a population of 32,200 perſons, and Bradford the 78th., with 7,302 perſons, which are the only large towns near this canal ; which commences in the *Kennet and Avon* canal, at Monkton Coombe, and the main or Dunkerton line of canal terminates at Paulton ; but a rail-way continues it forwards to Tyning ; the Radſtock line or branch of canal proceeds from the laſt at Mitford mill, and terminates at Radſtock town ; but a rail-way continues it forwards to Welton colliery ; there are alſo rail-way branches from this line to Radſtock colliery, and to Smallcombe and Clandon collieries : from the main or Dunkerton line, there are rail-way branches to Mearns, Ameſbury's, Britton's, Saliſbury's, and Radford collieries. From the *Kennet and Avon* canal to Mitford mill is level, thence the main or Dunkerton line riſes 138 feet by 22 locks. The Radſtock line riſes about the ſame height from Mitford mill. The boats uſed are 72 feet long, and 7 feet wide. About July 1796, Mr. *Robert Weldon* began the erection of one of his diving or caiſſon locks at Coombe-Hay, for paſſing the boats through a perpendicular ſhaft, either in aſcending or deſcending. In November 1797, this apparatus was in ſufficient forwardneſs for the caiſſon to be ſunk and raiſed again in the ſhaft; and, in May 1798, a trial was made of this contrivance, ſo ſucceſsful, that the inventor then offered to undertake to paſs 1500 tons of goods in 12 hours through this 45 feet riſe or fall, without the loſs of any conſiderable quantity of water, and with the aſſiſtance of only one man, beſides the bargemen, to work the machinery. Theſe fair proſpects were, however, blaſted, by the bulging of the walls of the ſhaft, as we have already mentioned, in deſcribing this contrivance; and inclined planes were conſtructed at this place for letting down boxes full of coals, the deſcent of which, by means of ropes and wheels, drew up the boxes, either empty, or in part loaded with other goods: the delay and expence of this method being highly complained of, about September 1802, a new ſubſcription was ſet on foot, and encouraged by the *Kennet and Avon* and *Wilts and Berks* companies, for ſubſtituting locks, 22 of which were completed, and opened on the 5th of April laſt (1805). Mr. *John Rennie*, Mr. *William Bennet*, Mr. *Charles Wedge*, and Mr. *William Smith* were the engineers conſulted or employed upon this canal, which, in January 1801, was completed from Dunkerton to ſeveral of the coal mines, and which, (after 4 miles of land carriage,) had the effect of lowering coals at Bath from 14d. or 15d. per cwt. to 9d. or 10d. This company was authoriſed to raiſe 185,000l., the amount of ſhares 100l. each. Before undertaking any of the rail-way branches to the collieries, this company might require ſecurity from the owners of ſuch collieries, that the tolls thereon ſhould produce, or be made up, to a certain rate of intereſt on the coſt of ſuch branches. The profits of this concern are not to exceed 10 per cent.; but after 1000l. is accumulated and placed in goverment ſecurities, as a fund for contingencies, the tolls on coals are to be lowered. Huſbandry and pleaſure boats 12 feet long and 5 feet wide may be uſed toll free on the pounds, or where the water flows waſte over the lock-weirs. A tunnel, $\frac{3}{4}$ of a mile long, was at firſt propoſed near Coombe-Hay, but by a ſubſequent alteration of the line this was avoided. The rates of tonnage in the firſt act may be ſeen in *Phillips*'s 4to. *Hiſtory*, *App.* p. 163 and 164, including the tolls on horſes, cattle, ſheep, &c. travelling on the rail ways; by the laſt act ſome of the tolls were increaſed. Dunkerton mill was purchaſed by this company, and ſteam-engines were erected to pump up water for ſupplying the upper pounds. In ſeveral places this canal was cut through *ſtrata* diſpoſed to ſlip, but by the ſmall tunnels or ſoughs which Mr. *William Smith* conſtructed, for draining off the ſprings, the ſame was prevented. On the 3d of May, 1804, a ſudden and great flood happened, which required, it was ſaid, ſome of the banks of this canal to be cut in proper places, to give vent to the water.

SOUTHAMPTON AND SALISBURY CANAL. Acts 35 and 40 of Geo. III.—The general direction of this canal is nearly N.W. for about 17 miles, in two detached lengths, in the counties of Hants and Wilts; it is not greatly elevated; its objects are the trade between Southampton and Saliſbury, the ſupply of theſe towns, and the export of the ſurplus farming products of the intermediate country. This canal commences in the *Itchin* river, at Northam near Southampton, and proceeds along the N.E. ſhore of *Southampton water* to the *Andover* canal at Red-bridge. In the *Andover* canal (about $9\frac{1}{2}$ miles above Red-bridge), near Kimbridge mill, this canal commences again, and proceeds to the *Avon* river at Saliſbury, or New Sarum. Southampton is the 68th Britiſh town, with a population of 7,913 perſons, and Saliſbury is the 70th, with 7,768 perſons: Romſey is alſo a conſiderable town near this line. The eaſtern part of this canal, between Northam and Red-bridge is level, and but little elevated by its tide-locks, above the tide-way in *Itchin* river and *Southampton Water*; from its ſkirting along cloſe to the ſhore of the latter river, it was that that facetious ſatiriſt *Peter Pindar* took occaſion to burleſque "Southampton's wiſe ſons." Upon this part of the canal there is a tunnel of conſiderable length cloſe to, and indeed under part of the north end of Saliſbury town; conſiderable difficulties ſeem to have attended the making of this tunnel, owing to the looſeneſs of the ſoil; and the quick-ſands at the foot of the cliff, by the ſide of *Southampton Water*, have alſo proved a very ſerious obſtacle. An aqueduct is built over Shirley Brook; ſprings within 1000 yards of the canal may be taken for its ſupply, which is alſo to be aided by ſome reſervoirs, which were begun in 1796. This company have been authoriſed to raiſe 96,000l. the amount of each ſhare being 100l. Mr. *John Rennie* is the engineer; the eaſtern part of the canal was begun in 1796, and was ſaid, in 1803, to be nearly done, but it is not yet opened. The weſtern part from the *Andover* canal at Kimbridge was completed to Deane, in October 1798. Stones are to be erected on the banks of this canal, at every $\frac{1}{4}$ of a mile diſtance.

SOUTHAMPTON WATER. Acts 11 Henry VII. and 18 Henry VIII.—This noble eſtuary of the Anton and other rivers has a N.W. direction for about 10 miles in Hampſhire. The tide flows through its whole length, and through a branch thereof more than 5 miles in length to near Botley; *Southampton water* is navigable for large ſhips; it commences in the channel between Hampſhire and the Iſle of Wight at Calſhot Caſtle, and terminates near Red-bridge where it is joined by the Anton river (formerly navigable near 6 miles to Romſey), and the *Andover* canal near one of the terminations of the *Southampton and Saliſbury* canal; near Saliſbury it is joined by the *Itchin* river, (about $\frac{3}{4}$ of a mile from the commencement of the *Southampton and Saliſbury* canal.) In the 43d of Geo. III., an act paſſed for enlarging and improving the quay and harbour of Southampton, by building a pier and other works which commenced in December 1803, and have ſince been proceeding.

STAFFORDSHIRE and WORCESTERSHIRE CANAL. Acts 6, 10, and 30, of Geo. III.—The general direction of this canal (ſometimes called the Wolverhampton canal) is nearly north for $46\frac{1}{2}$ miles in the counties of Worceſter and Stafford; its middle part is very conſiderably elevated, and it croſſes the grand-ridge without a tunnel; its trade in the export of coals, pottery-wares, hard-wares, &c. is immenſe, beſides the general trade between the *Severn*, the *Merſey*, and *Trent*, which for a long time paſſed excluſively through it. Near to Stourton, and to Stewponey, it is joined by the *Stourbridge* canal, and at Alderſley or Autherley by the Old *Birmingham* canal. Wolverhampton is the 33d Britiſh town with 12,565 inhabitants, and Kidderminſter is the 95th with 6,110 perſons: Bewdley, Stourbridge, Penkridge, and Stafford, are alſo conſiderable towns on or near to this canal; which commences in the *Severn* river at Stourport, and terminates in the *Trent and Merſey* canal at Great Haywood. From the *Severn* river at Stourport, to the *Stourbridge* canal at Stewponey, $12\frac{1}{4}$ miles, is a riſe of $127\frac{1}{2}$ feet by 13 locks; thence to Tettenhall, the beginning of the ſummit-pound, 11 miles, is a riſe of $166\frac{1}{2}$ feet by 18 locks; thence to the old *Birmingham* canal, $1\frac{1}{4}$ mile, is level; thence to Street-way, $8\frac{3}{4}$ miles, is level to the N. end of the ſummit-pound; thence to the *Trent and Merſey* canal at Haywood, $13\frac{1}{4}$ miles, is a fall of $100\frac{1}{2}$ feet by 13 locks. This canal is 30 feet wide at top, and 5 feet deep, though the depth of water on the lock-ſills is only 4 feet. The locks are 74 feet long and 7 feet wide; and ſeveral of them are built of a red kind of free-ſtone; the boats in general carry 20 tons. At Stourport are two baſons belonging to this canal connected with the Severn river by flood-locks to keep the water in them always at one certain height. On this canal are three ſhort tunnels; one is near to Stewponey, the other at Whitlington, and the other is an arched-way under part of the town of Kidderminſter; at which place there is an aqueduct-bridge over the Stour river, another at Preſtwood on Wordſley brook, another near Milford on the Sow river, and another at Haywood mill over the Trent river. In Chillington is a large reſervoir, and at Moſeley another, whoſe waters are conveyed to the ſummit-pound by feeders of conſiderable length. This company may make branches to any place within 1000 yards of the line by conſent of the land-owners. Mr. *James Brindley* was the engineer to this canal, which he began in September 1766, aud finiſhed in 1772. The firſt lock which this engineer erected was at Crompton, on this canal. This company were authoriſed to raiſe 100,000l., the amount of each ſhare being 100l. In September laſt (1805), the yearly dividend on theſe was ſtated to be 24l. The rates of tonnage are ſtated (in Mr. *John Cary*'s excellent work with maps, now publiſhing in numbers, on Inland Navigation,) to be $1\frac{1}{2}$d. per ton (2400lb.) per mile on all kinds of articles except lime and lime-ſtone, which pay only $\frac{1}{2}$d. per ton; and paving and road materials, and manures for adjoining lands which are to paſs toll free on the pounds, and through the locks when the water flows over the lock-weirs. By the *Dudley* act (16 Geo. III.), coals brought from that canal and carried on this may be charged 2d. per ton per mile, but commiſſioners may authoriſe lowering this toll. The uſual charge made by bargemen in 1796 for freight (including the company's tonnage) was, for periſhable goods $2\frac{1}{2}$d. per ton per mile, and for heavy unperiſhable goods 2d. In 1802, a tunnel 5 feet in diameter and 135 feet long, compoſed of cylinders of caſt-iron, was laid under the river Penk near this canal for draining a moraſs of 500 acres. In the laſt ſeſſions (45 Geo. III.) application was made by this company for a new act, to raiſe the tolls in order to make new locks, the old ones in ſome places being decayed and nearly worn out, and for making ſome new rail-way branches. The *Stour* river between Stourport and Stourton, by the ſide of this canal, was made navigable ſeveral years ago, but the works thereon were ſoon after deſtroyed by a great flood. In the preſent month (November 1805), a rail-way branch from Latherford in Shareſhill is propoſed, to Mr. Henry Vernon's collieries in Buſhbury.

Stainforth and Keadby Canal. Acts 33 and 38 of Geo. III. The general direction of this canal is nearly W.; for 15 miles in the counties of Lincoln and York, it has its courſe through level fens and is but little elevated above the level of the ſea; its objects are the import of coals and export of agricultural produce, with a better drainage of the country through which it paſſes. Thorne is the only conſiderable town near this line; which commences in the *Trent* river at Keadby, and terminates in the *Don* river at Fiſhlake near Stainforth, having alſo a branch 1 mile in length which joins the *Don* river at Hangman-Hill in Thorne; the whole is on one level, having tide or flood-locks at its extremities to regulate its height notwithſtanding the variable tides and floods in the adjoining rivers. A reſervoir of 5 acres is conſtructed on Thorne Common, and the waſte water from this canal is to be diſcharged into the *Trent*. In 1762, when Mr. *John Smeaton* was conſulted about the drainage of Potterick Car, a navigable canal through theſe fens was in contemplation. This company were authoriſed to raiſe 54,200l., the amount of ſhares being 100l. each.

Stoke River. The direction of this river (ſometimes called the Winſon) is W. for about $8\frac{1}{2}$ miles in the county of Norfolk; it is embanked nearly its whole length through the fens, and is but very little above the ſea; its objects are the import of coals, deals, &c. and the export of agricultural products. Downham is the only conſiderable town near it; it commences in the Great *Ouſe* river between Denvers-ſluice and Salters-Load, and terminates at Stoke-Ferry near the town of Stoke.

Stort River. The general direction of this river is almoſt N.E. by a bending courſe of about 13 miles between the counties of Eſſex and Hertford; its northern extremity is conſiderably elevated; its objects are the import of coals, deals, &c. and the export of farming products. Hoddeſdon and Biſhopſtortford are conſiderable towns near this river; which commences in the *Lea* river near Hoddeſdon, and terminates at Biſhopſtortford. In 1785, this navigation was propoſed to be joined at its northern end by the *Biſhopſtortford and Cambridge*, and in 1789, it was intended to join the *Biſhopſtortford and Wilton* at the ſame place.

Stour River (*Chriſtchurch*.) The direction of this river is nearly N.W. for about 35 miles in the counties of Hants and Dorſet; its northern end is conſiderably elevated; its objects are the import of coals, deals, &c. and the export of farming products; Chriſtchurch, Wimborn-Minſter, Blandford-Forum, and Sturminſter-Newton, are conſiderable towns on this river; which commences in the tide-way in Chriſtchurch-bay at Chriſtchurch-harbour, and terminates at the town of Sturminſter. At Gains-croſs in Shillington-Okeford, it is to be joined by the *Dorſet and Somerſet* canal. In 1762, Mr. *John Smeaton* was conſulted on the intended improvements in Chriſtchurch-harbour; the ſpring-tides in this harbour flow only 5 to 7 feet, and the neap-tides no more than 4 to 6 feet; and 3 hours after high water there is a ſecond or ſmaller tide, which flows in the harbour from 8 to 18 inches, being greateſt at the neap-tides. In the reign of Charles II., a pier of 256 yards in length, was conſtructed of lumps of iron-ſtone out of the looſe ſandy-cliff near it, and Mr. *Smeaton*, in 1764, planned another pier to be built for the better ſecurity of this harbour.

Stour River (*Harwich*.) The general direction of this river is nearly W. by a bending courſe for about 29 miles between the counties of Eſſex and Suſſex; the firſt 10 miles is a wide eſtuary through which the tide flows, the weſtern end is not greatly elevated; its objects are the import of coals, deals, &c. and the export of farming products; Harwich, Manningtree, Neyland, and Sudbury, are conſiderable towns on this river; which commences in the *Stowmarket and Ipſwich* navigation (near its junction with the German Ocean) at Harwich, and terminates at Sudbury.

Stour River (*Sandwich*.) Act 7 Henry VII.—The general direction of this river is nearly W. by a crooked courſe of about 18 miles in the county of Kent; it is but little elevated above the ſea in any part; its objects are the ſupply and trade of Canterbury, and the export of farming products. Canterbury is the 57th Britiſh town with a population of 9,000 perſons, and Sandwich is the 93d with 6,506 perſons, Ramſgate is alſo a conſiderable place near to this river; which commences in the Engliſh Channel or

Downs at Sandwich Haven (1½ mile from Ramſgate-harbour), and terminates at the city of Canterbury; the lower end of this river, for 1½ mile in Pegwell bay, has its courſe through ſhifting ſands which are dry at low water, and covered at high water; it is therefore unſuited for large veſſels to enter, and *Ramſgate harbour* is the only ſecure retreat for ſhips in caſe of a ſtorm on this part of the coaſt. The celebrated piers which form this harbour were begun in 1749; the ſouthern pier extends 800 feet eaſtward into the ſea, it then returns northward, forming the front next the Downs, by a polygon of 5 ſides, each 450 feet in length; theſe are joined at their angles by octagons of ſolid maſonry that are 60 feet acroſs; the breadth of the pier at top including the parapet is 26 feet, and the whole is built of hewn Portland and Purbeck ſtone. The entrance for ſhips is from the north nearly, and is 200 feet wide, having a light-houſe with Argand's reflecting lamps on its weſt head, and this is connected with the ſhore by a ſimilar, though ſhort pier, as on the ſouthern ſide. The area of the famous harbour, thus formed in the open ſea, is 46 acres, and it is deep enough to receive ſhips of 4 or 500 tons burthen. A ſpacious dry-dock for the repair of ſhips connects with this harbour. In a few years after the piers were completed, this harbour was nearly choaked with mud depoſited by the tides. Mr. *John Smeaton*, who was conſulted, erected a croſs-wall at the uppermoſt extremity of the harbour with numerous ſluices therein, by the drawing of which, after the tide has retired and left this reſervoir full of water, the mud has been ſince effectually ſcoured out; this excellent engineer alſo extended the pier 400 feet at the head. Nearly 300 ſhips have been known at once to aſſemble in this harbour for ſhelter on the approach of a ſtorm. An act 5 Geo. III., paſſed for improving this harbour as above, and by 37 Geo. III. the tonnage charged on veſſels paſſing the Engliſh Channel for the ſupport of Rye-harbour, was transferred to this harbour as before mentioned. In the years 1802 and 1804, the *Canterbury and Nicholas-bay* canal was intended to join the *Stour* river at Canterbury; and in 1802, the *Medway and Rother* canal was propoſed to join it near the ſame place.

*Stour River* (*Stourbridge.*) Many years ago the *Stour* river from the *Severn* at Stour-port to the town of Stourbridge, (paſſing the town of Kidderminſter,) about 14 miles, was made navigable by means of ſluices, weirs, and other works; but ſoon after there happened ſo ſudden and violent a flood as to deſtroy all theſe works. The *Stafford and Worceſter*, and the *Stourbridge* canals, have ſince ſupplied more effectually the place of this river navigation.

STOURBRIDGE CANAL. Acts 16 and 22d of Geo. III. The general direction of this canal is nearly E. by a crooked courſe of about 5 miles in the county of Stafford; its eaſtern end is conſiderably elevated, and extends within about 3 miles of the grand-ridge on its eaſtern ſide; its objects are the export of coals, iron-ſtone, &c. and forming part of the communication between the Old *Birmingham* and the *Severn*, &c. Stourbridge and Dudley are conſiderable towns near this line; which commences in the *Staffordſhire and Worceſterſhire* canal near Stourton and Stewponey, and terminates in the *Dudley* canal at Black-Delph; there is a branch of near 1 mile to the town of Stourbridge, and a branch of 2 miles to Penſnett-Chaſe reſervoir, with a ſide-branch thereto of near ¾ of a mile in Brierly pariſh. From the *Stafford and Worceſter* canal to near Stewponey, ⅜ of a mile, is a riſe of 43¼ feet by 4 locks; thence to the Stourbridge branch, 2 miles, is level; thence to the Lays, 1⅛ mile, has a riſe of 148 feet by 16 locks; thence to the *Dudley* canal, 1½ mile, is level; the Penſnett and Brierly branches are level with the laſt or ſummit-pound, and the Stourbridge branch is level. The width of this canal is 28 feet, and the depth of water 5 feet. The Penſnett-Chaſe or Fen reſervoir is 12 acres in extent, for ſupplying the head-level of this canal. This company were at firſt authoriſed to raiſe 30,000l. in 100l. ſhares; the laſt act authoriſed calling upon the ſubſcribers for 7,500l. more, by which their ſhares are now increaſed to 125l each. The rates of tonnage will be found in Mr. *John Cary*'s *Inland Navigation*, pages 50 and 51. Goods may be navigated on the ſummit-level toll free; and road-materials and manures for adjoining lands, may alſo be carried on any of the pounds toll free. Leſs than 15 tons are not to paſs any lock without conſent. Side-branches may be made to the adjacent collieries. The *Worceſter and Birmingham* company were bound (act 31 Geo. III.) to make up the profits of this concern to 9 per cent per annum, in caſe of their canal leſſening the trade thereon; but on the extenſion of the *Dudley* canal to join the *Worceſter and Birmingham*, the laſt mentioned company were exonerated therefrom, and the *Dudley* engaged (33 Geo. III.) to make up the annual dividend on the ſhares in this concern to 12l. each; but not to exceed 3l., and this when their own canal yielded a dividend of 5l. per ſhare. The part of this canal below Stourbridge ſupplies the place of the river *Stour* navigation, which was deſtroyed by floods as above mentioned. In 1786, the *Stourbridge and Worceſter* was propoſed to join this canal at Stourbridge; as was alſo a branch ſince propoſed from the *Worceſter and Birmingham*.

*Stourbridge and Worceſter.* In 1786, a canal was propoſed, and ſupported by the late lord *Dudley and Ward*, from the *Severn* river at Diglis below Worceſter city to the *Stourbridge* canal at that place, paſſing Bromſgrove; its propoſed length was 26 miles with 772 feet of lockage, by 128 locks; ſome tunnels and other large works were neceſſary; a bill for this canal paſſed the commons, but was rejected by the houſe of lords.

STOVER CANAL. Act 32 Geo. III.—The general direction of this canal is nearly N.W. for 6½ miles in the county of Devon; it is but little elevated; its objects are the import of coals, ſhelly ſea-ſand and lime, as manures, and the export of potters' clay (uſed in Staffordſhire, Lancaſhire, &c.) and a peculiar kind of imperfect coal found in ſmall quantities at Bovey-Tracey; Newton-Buſhel and Chudleigh are conſiderable towns near this canal, which commences in the tide-way in the *Teign* river at Newton Abbots, and terminates at Bovey-Tracey, with a branch of 5½ miles to the town of Chudleigh. From Newton-Abbots to Newton-Buſhel, 1 mile, is a riſe of 20 feet; thence to Bovey, 5½ miles, is 30 feet riſe; the Chudleigh branch is level. *James Templer*, eſq. is the ſole proprietor of this canal, and Mr. *Gray* was his engineer. At Teigngrace, and the adjoining pariſhes, the ſurplus water of this canal has been applied to the irrigating of the lands below it, a capital improvement, which we are very anxious to ſee more generally adopted.

*Stowmarket and Bury Rail-way.* In December, 1802, it was in contemplation to make a rail-way from the *Stowmarket and Ipſwich* navigation at Stowmarket, to the *Lark* river at Bury St. Edmunds, for the purpoſe of ſupplying the latter place, and the intermediate country with coals; (the *Lark* navigation being often interrupted by droughts in the autumn;) and for the readier export of farming products.

STOWMARKET AND IPSWICH NAVIGATION. Acts 33 and 45 Geo. III.—The general direction of this navigation (which follows the courſe of the Orwell river) is nearly N.W. for about 26 miles, in the county of Suffolk, the firſt 13 miles, to near Ipſwich, being a wide channel or eſtuary in the tide-way, the remainder is not greatly elevated; its objects are the import of coals, deals, &c. and the export of ſarming products; it is joined by the *Stour* river near Harwich. Ipſwich is the 41ſt Britiſh town, with a population of 11,277 perſons. Harwich, Needham, and Stowmarket are alſo conſiderable towns near this navigation; which commences in the German ocean at Landguard fort, and terminates at the town of Stowmarket. This company were, by an act prior to the above, authoriſed to raiſe 14,300l. by the firſt act above 15,000l. more might be raiſed; the laſt act was for improving the port of Ipſwich by deepening the ſame, ſo that ſhips might unload at the wharfs, &c. In December, 1802, it was propoſed that the *Stowmarket and Bury* rail-way ſhould join this navigation at Stowmarket.

STRATFORD CANAL. Acts 33, 35, and 39 Geo. III.—The general direction of this canal is nearly N. for 23½ miles, in the counties of Warwick and Worceſter; it is very conſiderably elevated, and croſſes the grand-ridge: its objects are the export of coals, lime, and paving-ſtones, and as a link in the great chain of canal communication; at Kingſwood in Rowington a branch of this canal connects with the Warwick and Birmingham: Stratford-upon-Avon and Henley are conſiderable towns on or near this canal, which commences in or near the *Avon* river at Stratford, and terminates in the *Worceſter and Birmingham* canal at King's Norton, about 6 miles from Birmingham. From near Hockley there is a branch 2½ miles long to Tanworth quarries; from near Lapworth there is another branch of 1¾ miles to the *Warwick and Birmingham* canal; and from near Wilmcote is a branch of 4 miles to Temple-Grafton lime-works, with a branch of about 1 mile from this cut to Aſton-Cantelow. From Stratford to near Copnas-hill, 1½ mile, is level; thence to Wilmcote, 1 mile, has a riſe of 86 feet; thence to Preſton-mill, 6 miles, is level; thence to Preſton-green, 1¾ mile, is a riſe of 76 feet; thence to Lapworth-hall, 1 mile, is level; thence to Hockley Heath, 2¼ miles, is a riſe of 147 feet; and thence to the *Worceſter and Birmingham* canal, 10 miles, is level; the Tanworth branch is level, and connects with the ſummit-pound: the Temple-Grafton cut is level for the firſt 2½ miles, and in the next 1½ mile the riſe is 20 feet. Near Milepole hill is a tunnel of 320 yards in length; there are ſeveral ſmall aqueduct bridges; and ſome deep-cutting near Waring's Green. In May 1796 the ſummit-level of this canal from the *Worceſter and Birmingham* canal to Hockley-heath was completed and opened. This company was authoriſed to raiſe 225,000l. the amount of ſhares 100l. The rates of tonnage and exemptions are very long; ſee *Phillips*'s 4to. *Hiſtory*, *Appendix*, p. 111 and 112. At the junction with the *Worceſter and Birmingham* canal ſtop-gates are to be erected, to be ſhut and locked by either company, when the ſupplies of the other canal fail in dry ſeaſons; with the *Dudley* and *Worceſter and Birmingham* canals there are a number of regulations as to tonnage, in the ſecond act above (35 Geo. III.). About the year 1792 the *Stratford and Croperdy* canal was propoſed to join this at Stratford.

*Stratford and Croperdy.* About the year 1792 a canal was propoſed to connect with the *Avon* river and *Stratford* canal at Stratford, and proceed to the *Oxford* canal at Croperdy, by a courſe of about 31 miles in length; this being the ſouthern part of the propoſed line between Dudley and Croperdy; the northern part thereof being ſince occupied by the *Stratford* and the *Dudley* canals.

STROUDWATER CANAL. Acts 34 Geo. II. 15 Geo. III. 23 (for *Thames and Severn*,) and 33 and 37 Geo. III. (for *Glouceſter and Berkley*).—The general direction of this canal is about E. for 8 miles, (following nearly the courſe of *Stroudwater* river,) in the county of Glouceſter; it is not greatly elevated; its objects are the import of coals, and forming part of the firſt direct communication between the *Severn* and *Thames and Iſis* rivers; at Wheatenhurſt the *Glouceſter and Berkley* canal croſſes and connects herewith. Stroud is the 114th Britiſh town, with a population of 5,422 perſons. This canal commences in the *Severn* river at Framiload, and terminates in the *Thames and Severn* canal at Wallbridge near Stroud; from the *Severn* to the *Thames and Severn*, there being a riſe of 108 feet: this canal is wide enough for the Severn river boats. The engineers were Mr. *Thomas Yeoman* and Mr. *Robert Whitworth*. The firſt of the above acts was for powers to raiſe 20,000l. in 200l. ſhares, intending to execute the works under the powers of an act of 2 Geo. II. for improving the *Stroudwater* river, but ſeveral expenſive law-ſuits put a ſtop to the works, as we have already mentioned, until the ſecond act was obtained: a double lock of 14 feet riſe on this canal had a ſlipping bank of earth 20 feet high by its ſide, and gave immenſe trouble, to prevent the walls thereof being bulged in, this was at laſt accompliſhed by the turning of two dry drains of four feet diameter, between the lock and the bank. In 1802 the dividends on ſhares in this concern were 6l. each, and their price was about 225l. This canal has no horſe towing-path, but ſtiles are erected thereon, and the barges are hauled by men. Where this canal croſſes the *Glouceſter and Berkley*, ſtop-gates are to be erected to prevent this canal from loſing its water; no dues are to be taken for veſſels croſſing either of theſe canals. If, while the *Glouceſter and Berkley* is cutting, the navigation of this canal is interrupted, five guineas per day are to be paid to this company; veſſels paſſing to or from the *Berkley and Glouceſter* canal and this, are to pay the ſame tonnage as to and from the *Severn* at Framiload. This company are authoriſed to take 2s. 3d. per ton for coals which paſs through this canal, and on the *Thames and Severn* canals, but not beyond Brinſcomb bridge thereon, and for ſuch coals as paſs eaſtward of Brinſcomb bridge, 1s. per ton.

*Stroudwater River.* The act of 2 Geo. II. paſſed for making this river navigable between the *Severn* and the town of Stroud, a diſtance of about 8 miles, as above; but the oppoſition of the millers and others prevented its being accompliſhed, until 34 Geo. II. when Mr. *Bridge* undertook to conſtruct the navigation, without waſte of water or prejudice to the mills, by means of cranes to hoiſt the goods in boxes out of the boats in one pound, and place them in others in the adjoining pounds, as we have before deſcribed; but this ſcheme miſcarried, and the projectors were nearly ruined: at length the *Stroudwater* canal was conſtructed by the ſide of this river as above.

SURREY IRON RAIL-WAY, (*Northern part*). Acts 41 and 45 Geo. III.—This, the firſt public rail-way conſtructed near the metropolis, has about a S.E. direction, for 10 miles, in the county of Surrey: its ſouthern end has a conſiderable elevation: its objects are the import of coals and manures, and the export of chalk, flint, fire-ſtone, fullers'-earth, and agricultural products. Croydon is the 108th Britiſh town, with a population of 5703 perſons; Wandſworth is alſo a conſiderable town on this line; which commences near the tide-way in the river *Thames* at Wandſworth, and terminates at the turnpike-houſe S. of Croydon, in the ſouthern part of the *Surrey iron-rail-way*; at the N.W. extremity of Croydon the line of this rail way is but about ⅜ of a mile from the *Croydon* canal; from Mitcham common a branch goes off for about 1½ mile to Mr. *Shipley's* ſkinning mill at Carſhalton; and, to Meſſrs. *Were* and *Burſh*'s oil-mill, about ¼ of a mile, there is another branch at Garrat-lane. This rail-way has nowhere a greater aſcent than about 1 inch in 10 feet: it is double throughout, with numerous croſſing places for the carriage out of one road or track into the other,

other; of theſe we have already given a particular account, as alſo of the contrivances for ſhooting the contents of the rail-way waggons, on ſome occaſions, into barges lying in the entrance baſon at Wandſworth, which is about ¼ of a mile long, with a lock next the *Thames*, and is ſpacious enough to hold 30 barges or more at once, ſeveral of which can lie along the wharf to load or unload at the ſame time. The width of each track is about 5½ feet, the waggons carry about 3⅕ tons each, and ſeveral of them are often linked together to be drawn by one horſe. This rail-way croſſes the Wandle river twice on wooden bridges. On the 9th of January, 1802, the entrance baſon at Wandſworth was completed and opened; in October of the ſame year, the rail-way from the ſide thereof croſſing the turnpike road, and extending to Garrat was completed, and in the courſe of the preſent year it was opened to Croydon. The company were, by the firſt act, authoriſed to raiſe 50,000l. and a further ſum, by the act of the late ſeſſions, the amount of ſhares 100l. Few ſubjects have been more variably ſtated than the coſt per mile of this rail-way. Mr. *John Phillips*, after noticing in his *Hiſtory* the commencement of this work, adds, that iron rail-ways are made at an expence of about 300l. per mile. The original eſtimate was, we believe, 2000l. per mile; at a public meeting at Goſport, in September 1803, it was ſtated by ſome favourers of the extenſion of a canal from Croydon to Portſmouth, that the expenditure on this rail-way had amounted to 6,400l. per mile; but the advocates for extending this rail-way to Portſmouth inſtead of a canal, then contended that the expence did not exceed 4,500l. per mile; while Mr. *James Malcolm*, in his Agricultural Report on Surrey, juſt publiſhed, after ſtating the great pains he had been at to come at the facts, ſays, "inſtead, therefore, of the expence being 2000l. per mile, it appears as if it would be 7000l.!" (this includes all the expenditure of the company). The rates of tonnage are from 2d. to 6d. per ton, per mile, for different goods; and owners of adjoining lands may uſe the rail-way as a drift road. Ten pounds annually are to be paid to the city of London by this company, for connecting with the river Thames.

SURREY IRON RAIL-WAY) (*Southern part*). Act 43 Geo. III.—The general direction of this line of rail-way is nearly S. by a bending courſe of about 16 miles, in the county of Surrey; upon the chalk-hills or North Downs, it is greatly elevated; its objects are the import of coals and manures, and the export of chalk, lime, fire-ſtone, free-ſtone, flints, fullers'-earth, and agricultural products. Croydon is the 108th Britiſh town, with a population of 5,743 perſons; Ryegate and Godſtone are alſo conſiderable towns on or near this line, which commences in the northern part of the *Surrey iron rail-way* at Croydon turnpike, near the ſouthern end of that town, and terminates at Godſtone, paſſing near to the towns of Merſtham and Ryegate in its courſe. It has a riſe or fall of 1 inch in 10 feet, in croſſing the Downs: near to Merſtham is a conſiderable length of cutting 30 feet deep in ſome places, in order to obtain the proper deſcent; at Smitham-bottom is an embankment of 20 feet high, acroſs a valley, for the ſame purpoſe, with a road-arch under it; it croſſes the Croydon and Merſtham road in another place by an arch, and the road is ſunk conſiderably in order that the rail-way with its proper deſcent may paſs over it. The width of this double rail-way, including a path on each ſide for the carriage drivers is 24 feet. Some of the waggons hereon have their fore-wheels placed quite forward, and the hind-wheels nearly under the middle of the waggon, by which means ſtones, &c. can eaſily be ſhot out of them when required. Near to this rail-way at Merſtham there is a quarry of white ſoft free-ſtone (much ſimilar to the Totternhoe-ſtone on the *Grand-Junction* ſummit branch). The ſhares in this concern are 100l. each. In September, 1801, it was in contemplation to make a branch of this intended rail-way from near Ryegate to the *Arun* river at Wiſborough green; and another branch or rather an extenſion hereof, from near Godſtone to the *Ouſe* upper navigation at Linfield. About the month of June laſt (1805,) this rail-way between Croydon and Merſtham was opened, and 12 waggons loaded with ſtone, weighing 38⅕ tons, were drawn with eaſe by one horſe for 6 miles down the deſcent to Croydon-turnpike, in 1 hour and 41 minutes; from which place the ſame horſe ſet off again with 4 other loaded waggons attached, and perſons riding on them, making in the whole more than 55 tons, which it was ſaid he drew with apparent eaſe!

SWALE RIVER. The general direction of this river is nearly N.W. for about 35 miles, by a crooked courſe in the North Riding of Yorkſhire. Its northern end is very conſiderably elevated, and this river is ſubject to rapid and almoſt uncontroulable floods: its objects are the carriage of coals, and the export of farming products. Aldborough and Richmond are conſiderable towns near, or on this river, which commences in the *Yore* river at Myton; and the navigation was intended to terminate at Richmond. In 1767, Mr. *John Smeaton* was conſulted on the propriety of moving Topcliff mill to a new ſcite, in the deſign which the proprietors of this navigation had adopted of building new mills in ſeveral places, and on which it has been ſaid that 30,000l. was expended, and but a ſmall part of the above line was rendered effectually navigable. Mr. *John Smith* jun. was the reſident engineer. In 1801, the *Topcliff and Pierſbridge* was propoſed to join at Topcliff.

SWANSEA CANAL. Act 34 Geo. III.—The direction of this canal is about N.N.E. for 17½ miles in the counties of Glamorgan and Brecknock, in South Wales. Its northern end is conſiderably elevated: its objects are the export of coals and iron-ſtone, iron, &c. the carriage of lime to the intermediate works and country; and copper-ore, to the works, &c. Swanſea is the 99th Britiſh town, with 6,099 inhabitants. This canal commences in Swanſea harbour, in Swanſea bay, at the mouth of the Tave river, and terminates at Hen-noyadd lime-works: a part of this line between Llandoor brook and Morris town, 1½ mile in length, (called *Morris's canal*) through the eſtate of the *duke of Beaufort*, was conſtructed by that nobleman, who receives the tolls thereof. From near Swanſea to Llanſamlet is a branch of 3 miles in length; and a rail-way branch of about 2 miles to a large coal mine, where an audit or tunnel of 3 miles in length has been made under ground, and out of which 200 tons of coals are daily brought; on an inclined-plane on this branch, near 1 mile in length, the coal-waggons deſcend without horſes, regulated by a convoy or brake, as we have before deſcribed, and the empty waggons are drawn up the plane again by horſes. From the tide-way at Swanſea to oppoſite Pont-ar-Taw, 8¾ miles, is a riſe of 105 feet; thence to Pont Gwaynclawdd, 8 miles, is a riſe of 230 feet; and thence ¾ of a mile to Hen-noyadd is a riſe of 31 feet. An act 44 Geo. III. paſſed for amending two former ones, for building piers, and deepening and improving the harbour of Swanſea, under the direction of captain *Joſeph Huddart*. About the year 1797 the weſtern pier, extending 228 yards into the ſea, was completed; which had the effect of confining the current of the Tave river, and deepening the mouth of the harbour 2 feet: in 1802 this pier was extended 57 yards farther out, and in November 1804 a jetty thereto was completed. In April laſt (1805) a new pier was begun on the eaſtern ſide of the harbour, which is to be extended out and brought round weſtwardly, within 70 yards of the other pier, for effectually ſecuring and ſcouring the mouth of the harbour: dry and wet docks are alſo intended, and by embanking the river, a moſt ſpacious quay is to be formed. From this port, in 1768, only 694 ſhips cleared out; in 1790 theſe were increaſed to 1677 ſhips, and in 1800 to no leſs than 2590 of 134,264 regiſtered tons. Within 2 miles of Swanſea, ſeven large copper-works have of late years been erected, for ſmelting of roaſted ore from the Corniſh and Angleſea mines, brought in ſhips, which return laden with coals for working the mine-engines and roaſting the ore: the number of iron-furnaces, potteries, and other large works near this place are alſo conſiderable. This canal company was authoriſed to raiſe 90,000l., the amount of ſhares 100l. each; and it was provided in the act, that this canal ſhould be completed in 4 years; ſeveral rail-way branches may be made thereto. The engineer was Mr. *Thomas Sheaſly*, and the canal was completed and opened in October 1798. The rates of tonnage may be ſeen in *Phillips*'s 4to. *Hiſtory, Appen.* pages 166 and 167. Boats with leſs than 15 tons, when the water does, and 10 when it does not flow over the lock-weirs, are not to paſs without leave or paying for that tonnage. In the year 1804, 54,235 tons of coal and culver were brought down this canal for exportation, and the groſs tonnage on this canal amounted to 3590l. In Swanſea harbour, the *Swanſea and Oyſtermouth* rail-way connects with this canal.

SWANSEA AND OYSTERMOUTH RAIL-WAY. Act 44 Geo. III.—The general direction of this rail-way is nearly S.W. by a bending courſe, following cloſely the ſea ſhore, for about $7\frac{1}{2}$ miles in length in the county of Glamorgan, in South Wales: its object is the carrying of lime-ſtone, lime, and coals. Swanſea is the 99th Britiſh town, with 6,099 inhabitants. This rail-way connects with the *Swanſea* canal in Swanſea harbour, and proceeds thence to the Mumbles lime-ſtone quarries near Oyſtermouth. In April laſt (1805) this rail-way was nearly completed. There is a light-houſe on the Mumbles point for the ſecurity of ſhips entering Swanſea harbour, which was lately improved.

TAMAR MANURE NAVIGATION. Act 36 Geo. III.—The general direction of this canal is nearly N.W. for about 22 miles, following the courſe of the Tamar river, on the ſouthern coaſt of the counties of Devon and Cornwall. Its northern end is conſiderably elevated: its objects are the import of coals, and ſea-ſand and lime as manures; and the export of agricultural products. Launceſton is the only conſiderable town on this line; which commences in the tide-way in the *Tamar* river at Morwellham quay (the commencement of the *Taviſtock* canal) near Calſtock, and terminates at Tamarton bridge in North Tamarton, with a branch to Rich-mill grove in Launceſton. The *Tamar* is to be made navigable as far as Port-pool near Blanch-Down, before the canal commences. The locks are to be either about 5 feet or $9\frac{3}{4}$ feet wide, and $12\frac{1}{2}$, $24\frac{1}{2}$, or $36\frac{1}{2}$ feet long, in order to receive a number of ſmall boats, in length and ſide by ſide therein, as may be judged beſt. Inclined planes and rail-ways may be ſubſtituted in place of locks on the canal in any part. This company is authoriſed to raiſe 121,000l., the amount of each ſhare 50l. A feeder may be taken from the Tamar river, and all ſprings within 2000 yards of the head level, and within 1000 yards of every other part of the line; 200l. per annum is to be paid by this company to the duchy of Cornwall, for the liberty of making this navigation. We have not been able to learn what progreſs has yet been made in the cutting of this canal. By the act 14 Geo. III. a canal was intended, but never executed, through this line, and extending to the Iriſh Channel, called the *Bude and Launceſton* canal.

TAMAR RIVER. The general direction of this river is nearly north by a crooked courſe of about 6 miles, between the counties of Devon and Cornwall; the tide flows through its whole length; Beer-Aſhton is a conſiderable town near this navigation; which is uſed for the import of coals, ſea-ſand, lime, &c. and the export of ſlate and agricultural products. It commences in *Hamoaze* and terminates in the *Tamar Manure* navigation and *Taviſtock* canal, at Morwellham quay near Calſtock. In the year 1774, an act paſſed for the *Bude and Launceſton* canal intended to connect with this at Calſtock, but it was never carried into execution.

*Tarbeth Canal.* In 1773, Mr. *Watt* ſurveyed the iſthmus between Eaſt and Weſt *Tarbeth* lochs, on the weſt coaſt of Scotland, for a canal to communicate between Loch *Fine* and the ſound of *Jura*; the diſtance of high-water mark in the two lochs he found to be 1 mile, and the height of the ridge between them, 45 feet above high-water at neap tides. Mr. Watt's different eſtimates were, for a canal with locks 7 feet deep, 17,988l.; and for one 10 feet deep and a proportional width, 23,884l. The expences of a thorough cut without locks, of 12 feet deep at high-water, 73,849l., and for one of 15 feet deep, 120,789l. A very large canal has ſince been formed about 13 miles north of this, called the *Crinan* canal, which more effectually anſwers the purpoſe of communication between Loch *Fine* and the ſound of *Jura*.

TAVISTOCK CANAL. Act 43 Geo. III.—The general direction of this canal is N.E. for about $4\frac{1}{2}$ miles in the county of Devon; great part of it is conſiderably elevated above the level of the ſea: its objects are the export of ſlate, copper-ore, and other minerals, and of agricultural products; the import of coals, lime, and other articles for the ſupply of Taviſtock town and the ſurrounding country; and to facilitate the working of the mines in Morwellham down: this canal commences in the tide-way in *Tamar* river (near the commencement of the *Tamar Manure* navigation) at Morwellham quay new baſon, near Calſtock, and terminates at the town of Taviſtock. From Crebar near the north end of the tunnel, it has a branch of 2 miles to the ſlate quarries at Mill-hill bridge. From the *Tamar* river, $\frac{1}{8}$ of a mile is level with high-water at Morwellham quay; thence in $\frac{1}{4}$ of a mile, is a riſe of 237 feet; thence, about $3\frac{1}{8}$ miles to Taviſtock is level; the branch is level to New Quarry, about $1\frac{5}{8}$ miles; thence to Mill-hill bridge, $\frac{3}{3}$ of a mile, is a riſe of $19\frac{1}{2}$ feet. The locks upon this canal are to be calculated in length and width for the uſe of boats of $12\frac{1}{2}$ feet long, and 5 feet wide, either ſingly or ſeveral together, as on the *Tamar Manure* navigation above mentioned: but the company have the power to erect inclined-planes for boats, or boxes of goods, inſtead of locks, if they think fit. Through Morwellham down, which is of hard rock, and ſuppoſed to be interſected by ſeveral fiſſures, or loads filled with metallic ores, is to be a tunnel about 2500 yards long, and about 460 feet beneath the higheſt point of the down in its courſe: near Crebar is to be an embankment and aqueduct bridge 60 feet high, acroſs the Lumbourn river; which is to have a new courſe cut for it for a conſiderable diſtance near the branch of this canal below New Quarry. This canal is to be fed from the Tavy river at Taviſtock, and by any ſprings or ſtreams within 5000 yards of the line. Mr. *John Taylor* is the engineer to this canal and tunnel, which paſſes entirely through the eſtate of the *duke of Bedford*, who has leaſed to this company the mines which may be found in the tunnelling, or within certain diſtances of this canal. In February laſt

(1805) about 300 yards in length of the tunnel had been cut, and a known load of copper-ore had been interſected therein, which gave the beſt hopes of diſcovering other unknown ones, as the work proceeds. This company is authoriſed to raiſe 50,000l., and the amount of each ſhare is 50l. The rates of tonnage are for lime-ſtone conveyed through the tunnel, 1s. 3d. per ton; for building-ſtone, ſlates, bricks, tiles, clay, ſand, earth, dung, ores, iron, and metals (made marketable) conveyed through the tunnel, 2s. per ton; and for coals, coke, culm, lime, timber, bark, corn, grain, and all other goods paſſing through the tunnel, 3s. per ton; building-ſtone, ſlate, &c. as above, carried on the whole, or any part of this canal, or its branches, except in the tunnel, 1s. per ton; and coals, coke, &c. 1s. 6d. per ton. The laſt rates are not to be charged on any goods either carried or ſubſequently removed on any part of this canal, which have before paid the tunnel rates: and ores may be carried to the dreſſing-floors, or the waſte or rubbiſh of mines or loads be removed to proper places on any part of this canal or its branches, free of tolls. Beſides the above rates, all goods which paſs into, or from the *Tamar* river, and are not loaded at Morwellham quay, are to pay as follows for reimburſing the owner and occupiers thereof, for the loſs of wharfage on ſuch goods, viz. ſlate 3d. per ton, lime-ſtone 6d. per ton; ores, (made marketable) iron, bricks, tiles, clay, ſand, earth, and dung, 6d.; and all other goods 1s. per ton; and over and above this, one penny per ton is to be paid on all goods entering the canal baſon at Morwellham. The *duke of Bedford* may make collateral branches or rail-ways to this canal in any part.

TAVY RIVER. The general direction of this river is N.E. for about 2¾ miles in the county of Devon; the tide from the ſouth coaſt flows through its whole length: its objects are the import of coals, ſea-ſand, &c. and the export of ſlate, copper-ore, &c. It commences in *Hamoaze* and terminates at Lophill quay.

TAW RIVER. The direction of this river, or eſtuary, is nearly eaſt for about 8 miles on the north-weſt coaſt of Devonſhire: the tide flows through its whole length: its objects are the ſupply of Barnſtaple and the adjacent country with coals and other articles, and the export of farming products. This navigation commences in St. George's Channel, at Biddeford bay, and terminates at the town of Barnſtaple: near to Appledore the *Torridge* river joins this navigation.

TAY RIVER. The general direction of this river, firth, or eſtuary, is nearly weſt for about 26 miles, between Angus and Fife, and in the county of Perth in Scotland. The tide flows through its whole length: its objects are the ſupply and trade of Dundee and Perth, and the adjacent country. Dundee is the 18th Britiſh town, with 26,084 perſons, and Perth the 26th, with 14,878 perſons. This firth commences in the German Ocean, and terminates at Perth bridge. This bridge, built of ſtone by Mr. *John Mylne*, was ſwept away by a rapid flood in 1621. In 1763, Mr. *John Smeaton* was conſulted on the building of a new bridge; and in 1766 he began one of 7 arches, where the river was 893 feet wide: the depth of the Tay at this bridge at neap tides in dry ſeaſons was only 2 feet, at ſpring tides 10 feet deep. At Stanley, 7 or 8 miles higher up this river, three ſoughs or tunnels of conſiderable length (one of them from 12 to 9 feet wide arched with ſtone) are driven through the hill, which occaſions a great loop in the river, by which 24 to 20 feet fall is gained, for a large portion of the ſtream, to work cotton-mills and other machinery; and running in this ſubterraneous channel it never freezes.

TEES RIVER. The general direction of this river is nearly S. E. by a crooked courſe of about 12 miles, between the counties of York and Durham: the firſt four miles are by a very wide eſtuary: the tide flows through its whole length: its objects are the trade of Stockton, and the export of agricultural products. Stockton is a conſiderable town on this river; which commences in the German ocean, at Seaton Nook, and extends to the town of Stockton. In the preſent autumn there was an intention of improving this navigation. In 1803, the foundations were laid for an iron-bridge, to be erected under the direction of Mr. *Thomas Wilſon*, over this river at Yarm, a few miles above Stockton, in place of an old ſtone-bridge, whoſe clumſy piers had long obſtructed the current, and occaſioned the river frequently to overflow its banks. In 1768, the *Winſton and Stockton* canal was propoſed for extending this navigation weſtward to the coal diſtrict about Winſton.

TEIGN RIVER. The direction of this river, or eſtuary, is weſt for about 4½ miles in the ſouth-eaſtern coaſt of Devonſhire: the tide flows through its whole length: its objects are the import of Newcaſtle or Welſh coals, and the export of potters' clay, bovey-coal, and agricultural products: it commences in the Engliſh channel, and terminates at Newton-Abbots, at the commencement of the *Stover* canal, near to Newton-Buſhel.

*Ternbridge and Winsford.* In 1765, Mr. *Whitworth* propoſed a canal from the *Severn* river at Ternbridge below Shrewſbury, to the *Weaver* navigation at Winsford, 63½ miles, in the counties of Salop, Stafford, and Cheſter, with a branch therefrom, near Bridgeford; 43 miles, to the *Trent* river at Wilden-Ferry. From the *Severn* to the ſummit or grand-ridge (requiring 25 feet deep cutting,) below Offley-Park, 24 miles, is a riſe of 136¾ feet; thence to the Trent branch, (1¼ mile below Bridgeford,) 7¼ miles, is a fall of 54⅔ feet; thence to the ſummit or grand-ridge again, (requiring 25 feet deep-cutting,) in Madeley park, 10½ miles, is a riſe of 800¼ feet; thence to the *Weaver* navigation, 22¼ miles, is a fall of 284 feet: the branch from Bridgeford to the Trent has a fall of 209⅓ feet. The courſe of this canal is by Wansford, Allſcot, Crudgington, Chetwin-park, Batchacre-Grange, Eccleſhall, Standon, Wyburnbury, and Barten-croſs, near Nantwich. The branch is conducted by Stafford, Tixall, and thence following within a ſmall diſtance the courſe of the Trent river. This canal was propoſed to be 27 feet wide at top, 18 at bottom, and 5 feet deep, with a towing path on both ſides; the locks 60 feet long and 13 wide, and about 10 feet riſe each: the boats of 50 tons burthen: 78 road bridges, and 25 accommodation bridges were thought neceſſary, and 162 aqueducts and culverts: the eſtimated expence was 99,800l. The *Staffordſhire and Worceſterſhire* and the *Trent and Merſey* canals, which were adopted in the following year, embrace all the general objects of this canal. The *Sandbach*, and the *Newport and Stone*, have ſince been propoſed to occupy parts of the ſouth-weſtern end of this line, but, like this, were over-ruled.

THAMES RIVER, (*lower part*). Acts 19, 29, 39, 42, 43, 44, and 45 of Geo. III.—This fine river, by far the moſt important for trade, not only in Britain but in the whole world, has its career nearly weſt for about 72 miles between the counties of Kent and Eſſex, and Surry and Middleſex. The firſt 20 miles is by an exceeding wide eſtuary; the next 21 miles is ſtill an eſtuary of conſiderable width; the remaining 31 miles is crooked, and gradually diminiſhing: the tide flows very powerfully through its whole length. To enumerate its objects would be to recount almoſt every ſpecies of trade and commerce which is carried on in

Europe. At Eaſt Merſey it connects with the *Colne* river; at Weſt Merſey, with *Blackwater* river; at Foulneſs eaſt point, with *Crouch* river; at Whitſtable and at Sheerneſs, with the *Medway* river; at Graveſend, with the *Thames and Medway* canal; oppoſite to Purfleet, with the *Darent* river, or Dartford creek; at Bow-Creek, with the *Lea* river; at Blackwall and at Limehouſe-hole, with the *Iſle of Dogs canal*, (a new ſide-cut for ſhortening the navigation of this river); at Greenland-dock, and at Wilkinſon's gun wharf, Rotherhithe, with the *Grand Surry* canal; and, at Limehouſe, with the *Limehouſe* canal. London, the firſt Britiſh town, has a population of 864,845 perſons; Greenwich is the 31ſt, with 14,339 perſons; and Woolwich is the 53d, with 9,826 perſons; Margate, Feverſham, Milton, Queenborough, Sheerneſs, Leigh, Graveſend, Grays-Thurrock, and Deptford, are alſo conſiderable towns on or near this lower part of the *Thames* river; which commences in the Engliſh channel at Eaſt Neſs near Margate, and terminates in the *Thames*, middle part, at London-bridge. Large ſhips of war can come up to Deptford, and merchants' ſhips of 7 to 800 tons burthen frequently lie at the keys cloſe to London-bridge. The port of London, or part wherein the ſhips lie, generally called the pool, extends almoſt 4 miles, nearly to Deptford, in which ſpace more than 1000 veſſels have been ſeen moored at one time! the rapidly increaſing trade of this grand emporium of commerce, the regulations which have of late been made, for mooring the ſhips at more convenient diſtances, for a paſſage up and down the river, and the contiguity of the *Weſt India* and *Eaſt India* docks to Blackwall are expected ere long, to extend the tiers of ſhips as far as that place. It was ſtated, in the year 1800, that the trade of the port of London had increaſed in the laſt, or 18th century, by 6547 veſſels and 1,327,763 tons annually; and that (including repeated voyages,) 13,144 ſhips and veſſels were then employed in this trade, to foreign countries, the colonies, and coaſtwiſe, beſides 2288 lighters, barges, and punts, employed in the middle part of the *Thames*, and on the *Lea* river, and 3336 of the like kinds of veſſels uſed below bridge, in the lading and diſcharging of veſſels, together with 83 boats, ſloops, cutters, and hoys, 3000 watermen's wherries, 155 bum-boats, and 194 peter-boats, the total number, (excluſive of ſhips of war, tranſports, and navy and victualling and ordnance hoys,) being 22,500 veſſels of various ſizes and dimenſions, either trading to, or ſtationed within the pool or port of London; the total value of the goods imported and exported annually by them exceeding 67,000,000l.! The corporation of the city of London, as conſervators of the river *Thames*, and under the ſpecial authority of the above acts, are, at this time, carrying on conſiderable works for the improvement of this river: ſeveral mooring chains in the pool have been purchaſed of lord Guydir and others, and a harbour-maſter, approved by the Trinity-houſe, is appointed to regulate the mooring and conduct of veſſels, agreeable to the 19, 29, and 39 of Geo. III.: one of the largeſt canals ever attempted has been cut, near 1¼ mile in length, 142 feet wide at top, and 24 feet deep! acroſs the *Iſle of Dogs*, for ſhortening the paſſage of veſſels to and from the pool, and to avoid the long circuit by Greenwich and Deptford; Mr. *William Jeſſop* is the engineer, under whom the locks and other works of this canal were ſucceſsfully conducted and nearly finiſhed, when an unforeſeen accident, by the blowing up of the coffer and preventer dams, juſt as the entrance locks were completed, on the 24th of July laſt, (1805) prevented this canal from being opened until the 9th of December, when the Ducheſs of York, Weſt Indiaman, of 500 tons burthen, paſſed through the ſame, in preſence of the lord mayor and corporation of London. Several large ſums of public money have been granted by the above acts out of the conſolidated fund; for the repayment of which veſſels paſſing through this canal of 200 tons or upwards are to pay 2d. per ton; thoſe from 200 to 100 tons, 1½d. per ton: from 100 to 50 tons, 1d. per ton; 50 to 20 tons, 5s. each, and boats and craft 1s. each. Two or more piers are intended to be built at the entrance, for facilitating the entrance of veſſels to this canal. Between this canal and the entrance of the *Eaſt India* docks, there is a large maſs of ſilicious pudding-ſtone, conſiſting of chert pebbles imbedded in a very hard cement, which lies in the bed of the river, and has proved fatal to ſeveral ſhips, on which account the committee, in September 1802, and on ſeveral other occaſions, advertiſed for perſons who would undertake to lower this rock 18 feet, its length being about 40, and breadth 30 feet; the newſpaper accounts of the Boddington Weſt Indiaman having ſtruck on this rock on the 12th of September laſt appear to be incorrect, the rock being now ſurrounded by piles and booms, ſo that no ſhip can approach it. In the year 1773, Mr. *James Sharp* ſuggeſted the propriety of floating, or wet-docks, for the loading and unloading of ſhips in the Iſle of Dogs; after much diſcuſſion a plan was adopted for this purpoſe, in the year 1799, called the *Weſt India Docks*, and Mr. *William Jeſſop* and Mr. *Ralph Walker* were employed as engineers. On the 12th of July 1800, the firſt ſtone of this great undertaking was laid with much ceremony. On the 22d July 1802, an unfortunate accident occurred by the burſting of the coffer-dam at the entrance at Blackwall, but which did not prevent the great or import dock, from being opened for the uſe of Weſt-India ſhips on the 3d of September 1802. This fine dock, the largeſt in Britain, is 2600 feet long, 510 feet wide, covering more than 30 acres of ground; its depth being 29 feet, and it is walled in the moſt ſubſtantial manner with bricks, and coped with immenſe blocks of ſtone. Three ſtacks of the ſuperb warehouſes on the banks of this dock were completed at this time: on the 22d of Auguſt 1803, ſeveral other warehouſes on the N. ſide of the dock were finiſhed, and declared ready for public uſe; and, on 5th July laſt, two warehouſes on the ſouth ſide, and the whole of that quay were completed. The outward-bound dock, 2600 feet long, 400 feet wide, and 29 feet deep, has been rapidly proceeding ſince the completion of the great dock, and is now almoſt ready, we believe, for opening. At Blackwall, and at Limehouſe-hole, there are ſpacious entrance baſons, connecting by tide-locks with the *Thames* river; from theſe entrance baſons there are locks into the outward and inward, or export and import docks: theſe docks are calculated for the accommodation of 300 ſhips, 12 of which can conveniently enter or go out in one tide: there are to be ſix immenſe ranges of warehouſes in the whole, with cellars, cranes, and every poſſible convenience: the whole is to be ſurrounded with a wall 30 feet high, and a wet foſs 12 feet broad, and 6 deep: for ſecurity from fire, no dwelling-houſes or work-ſhops are to be built within or near to the boundary wall; no gunpowder is to be ſuffered to enter the walls, or any fire, candles, or lamps to be lighted within the ſame, except the neceſſary ſtreet-lamps on the quays. The company were at firſt authorized to raiſe 600,000l. the amount of ſhares being 500l. each, which, in 1802, bore a premium of 28l. per cent.: the profits to the ſubſcribers are limited to 10 per cent.: ſeveral loans of the public money from the conſolidated fund have been made towards completing this deſign. Mooring-chains are provided in the river oppoſite the entrance baſons, for the uſe of ſhips entering theſe docks, in which all Weſt India goods whatever (except tobacco in ſome caſes,) are to be landed, and all outward-bound ſhips for the Weſt-Indies are to load herein, or in the *Thames* at Blackwall ; but the tonnage for the building and maintenance of theſe docks is, (by 39 Geo. III.) not levied excluſively on the Weſt India trade, as every veſſel both on its inward and outward voyage (except coaſting veſſels under 45 tons, king's ſhips, corn, fiſhing, and paſſenger veſſels, and craft navigating above Graveſend,) is to pay : coaſting veſſels at the rate of 1d. per regiſter ton ; and ſhips trading to parts beyond the ſeas are to pay higher rates, amounting, in ſome caſes, to 3½d per ton ; ſee the particulars, as alſo the rates for wharfage, warehouſe-room, cooperage, &c. in the *Agricultural Magazine*, vol. i. p. 115. Mr. *Robert Edington*, in his *Eſſay on the Coal Trade*, 1803, after eſtimating 4284 coal-ſhips to enter the port of London annually from the neighbourhood of Newcaſtle-upon-Tyne, with 1071 chaldrons each, on the average, (a quantity conſiderably ſhort of the actual importation, ſee *Monthly Magazine*, vol. xvii. p. 99, and vol. xix. p. 99.) objects ſtrongly to the above rate, which annually taxes the coals conſumed in London and its vicinity with 4284l., on account of theſe docks, which they are not allowed to enter. For the general accommodation of ſhips unloading and loading in the port of London, another ſet of docks was, after much diſcuſſion, undertaken, in the year following, called the *London Docks*, (or ſometimes the Wapping Docks,) Acts 40, 44, and 45 of Geo. III. Mr. *John Rennie* and Mr. *Alexander* were the engineers employed ; on the 26th of June 1802, the firſt ſtone of theſe works was laid, by Mr. Addington, the then miniſter ; and the ſame proceeded without any diſaſter or impediment, until the great dock, the entrance baſon, and ſeveral of the warehouſes were completed, and opened for uſe on the 1ſt of February laſt (1805). The great dock is about 1260 feet long, and 830 feet wide, and covers about 24 acres of ſurface : it is 29 feet deep from the top of the walls ; but the depth of water is only 23 feet ; the walls are of brick, coped with ſtone, and every part of the work is executed in the moſt complete and maſterly ſtile. On the northern ſide of the dock there is an open ſhed the whole length, for examining and weighing and the landing of goods, under cover from the weather, from whence a number of ſmall trucks moving on rail-ways convey them to five immenſe ſtacks of warehouſes behind them, or the cranes hoiſt them into carts, as may be wanted. Near the S. E. corner of this dock are two immenſe warehouſes let to government for the ſtowage of tobacco ; one of them is 762 feet long, and 160 wide, the other 250 feet long, and 200 feet wide, each being in one ſingle room, without any partitions, and their roofs are ſaid to exceed 6 acres of ſlating ; they are but one ſtory high, but have ſpacious arched vaults under them of the ſame extent, for the ſtowage of wine, oil, ſpirits, &c. Other large ranges of warehouſes are to be built, and their fronts have been begun north of the preſent range of warehouſes ; the windows and doors of theſe laſt being bricked up, ſerve as a temporary wall to encloſe the premiſes : warehouſes are alſo intended on the weſt and ſouth ſide, where the high temporary fence-wall at preſent ſtands. The only entrance at preſent to this dock, from the *Thames*, is near to Bell-dock in Wapping, where two maſſive piers of ſtone project into the river, and have a tide-lock between them, and further north is a curious iron double ſwing-bridge, in the line of Wapping-ſtreet, which we have already deſcribed ; within this is the entrance baſon, of an irregular figure, of about 3 acres extent : this baſon is connected with the river at every high-water, by the opening of the gates, which ſhut again and retain the water at that height ; from this baſon ſhips lock up into the great dock, whoſe ſurface is kept about 3 feet above the height of ordinary tides, by a powerful ſteam-engine erected on the eaſt ſide of the entrance baſon for that purpoſe, and the bottom of the dock is about 15 inches above low-water mark in the river. There is deſigned to be another entrance from the *Thames* by means of Hermitage-dock, into the great dock at its S.W. corner ; and from near the oppoſite or N.E. corner, proviſion has been made, and the connecting canal formed, which is to join it with another large dock, intended to be dug, and connect with the *Thames* at Shadwell. Notices were given in September laſt of an application to parliament for further powers, to proceed with the above works. The preſent dock is capable of accommodating 200 merchant ſhips, and the entrance baſon will hold a vaſt number of ſmall craft, without impeding the paſſage of ſhips to or from the great dock. The whole of the docks or warehouſes are, when completed, to be ſurrounded by a very high wall to prevent depredations or the communication of fire, againſt the happening of which the ſame regulations are adopted as at the Weſt-India dock above mentioned. Six large mooring chains are fixed at proper diſtances from each other in the great dock for ſhips to moor to, conſiſting of very large floating blocks of deal timber. This company were authoriſed by their firſt act to raiſe 1,500,000l., the amount of each ſhare being 500l. They were required to purchaſe the concern of the Shadwell water-works for 50,000l. ; and ample proviſions are made for compenſating the owners of the river-quays, the proprietors of ſtreet-cart licences, &c. : and full accounts of the receipts and expenditure of this company, and of the Weſt-India dock company, are to be preſented annually to parliament. The tolls or rates payable to this company, by ſhips which enter their docks, are for Britiſh coaſting veſſels (including colliers) 1s. per ton ; five other claſſes of ſhips are enumerated, which are to pay from 15d. to 30d. per ton ; ſee *Agricultural Magazine*, vol. iii. p. 162. For the landing, loading, and houſing, and for ſhipping of goods of every different kind, the ſame ſums reſpectively are to be taken by this company, as were uſually paid at the different quays of the port of London in the year 1798. The whole of the ſcite of theſe docks was covered either with ſtreets and houſes, or with gardens, and which the company had to purchaſe for immenſe ſums of money. For the particular accommodation of the large ſhips belonging to the Eaſt-India company, a third ſpacious ſet of docks has been deſigned, and in the 43 of Geo. III. an act paſſed for enabling the company to raiſe 200,000l. for the purpoſe of building the *Eaſt-India Docks ;* and to purchaſe the dock belonging to Mr. Perry's maſt-houſe at Blackwall, for their entrance baſon. Mr. *Ralph Walker* is the engineer ; and on the 4th of March laſt (1805) the firſt ſtone of this great undertaking was laid by captain Joſeph Huddart, and the works are now proceeding with the utmoſt expedition : the largeſt, or import dock, is to cover 18 acres of ground, the export dock is to be 9 acres in content, and the entrance baſon about 3 acres : the depth of theſe docks is to be greater than either the *London* or the *Weſt-India* docks ; the entrance locks now building are 48 feet wide in the clear, and each gate is to be 27 feet wide. Near to Deptford, *Greenland-Dock* has its entrance, by a tide-lock, into the river *Thames ;* this dock is about 900 feet long and 400 feet wide, and was conſtructed ſeveral years ago, for the accommodation of ſhips employed in the Greenland, or whale fiſhery, with ſuitable conveniences at proper diſtances for melting and refining their oil. It is intended that the *Grand Surry* canal ſhall have a cut into, and a paſſage for its barges, through this dock : and the ſame company are now excavating a dock near the termination of their canal, at Wilkinſon's gun-wharf, Rotherhithe, which ſeems to be intended to admit ſmall ſhips from the *Thames*. At Deptford, Woolwich, and at Sheerneſs there are ſpacious dock-yards and naval arſenals on the banks of this river, and others at Chatham, within a few miles of it, on the *Medway* river. In the year 1800 it was propoſed to make a large dock and yard, for repairing ſecond and third rate ſhips of war, of which *Major General Bantam* has the direction, near the ſalt pans on the *Iſle of Grain*, on the *Medway* ſide of it: its principal object is for repairing the ſhips ſtationed in the Downs and North Seas. In the year 1804 it was propoſed to form a wet-dock, of about 12 acres extent, connecting with the *Thames* river, by *Northfleet* creek near Graveſend: the ſcite of the old chalk pits is intended to be excavated for this dock, in which the new ſhips of war built at Deptford, Woolwich, and Chatham are to be received to be rigged and fitted for ſea, inſtead of ſending them to Sheerneſs; that the arſenal there may be wholly appropriated to the victualling and ordnance department. A pier is now building for the protection of *Sheerneſs* harbour, under the authorities of the acts of 41 and 43 of Geo. III. At Margate, there was an ancient wooden pier in this river, for the protection of the hoys and veſſels trading to that place, but in 27 Geo. III. an act paſſed for an excellent ſtone pier, which has ſince been there erected. The great diſtance which the inhabitants of Graveſend, and Grays-Thurrock, and all thoſe parts, have to travel (over London bridge) to communicate with each other by land, gave riſe, in May 1798, to the propoſition by Mr. *Ralph Dodd* for a tunnel, or road-arch, under the *Thames*, from near Graveſend to Tilbury Fort (ſee Nicholſon's Journal, 4to. vol. ii. p. 473.); and an act of 49 Geo. III. paſſed to authoriſe the raiſing of 50,000l., in 100l. ſhares, for the *Thames Tunnel*, and to levy 2s. 6d. on each coach, 4s. on each waggon, 2s. on each cart, 1s. on each horſe, 2d. on each foot-paſſenger, and ſome other tolls, for paſſing through this tunnel. Government to pay 1000l. annually, in lieu of all tolls, for the paſſage of troops and of government ſtores of every kind: 80l. to be paid annually to his majeſty, and 30l. to the corporation of Graveſend and Milton, in lieu of the right of ferries, near the intended tunnel, to which they are entitled. Mr. *Dodd* propoſed his arch to be a cylinder of 16 feet diameter in the clear, and eſtimated that the ſame might be executed for 16,000l., the length of the tunnel being 900 yards; but it does not appear that at this time, or for more than two years after, any borings had been made, even on the ſhore of the river where the tunnel was intended, to prove whether the chalk rock, which Mr. *D.* had calculated upon tunnelling in, exiſted or not: at length, about September 1800, a bed of chalk, *ſuppoſed* to be the ſame which appears on the ſurface at Graveſend, was diſcovered, by Mr. *D.*'s borings, at 72 feet beneath the ſurface, at Tilbury Fort; a ſteam-engine was thereupon erected, and a perpendicular ſhaft of 146 feet deep was ſunk at Graveſend, all in chalk; when, by one of thoſe *unaccountable accidents* to which abortive ſchemes ſeem peculiarly liable, this engine-houſe took fire, and was burnt down, and ſhortly after the ſcheme was given up altogether. In the laſt ſeſſion of parliament (45 Geo. III.) an act paſſed for making other archways under the *Thames*, for the paſſage of carriages and foot paſſengers, between Rotherhithe and Limehouſe; and we have ſince read that Mr. *Robert Vazie* is the engineer to theſe *Rotherhithe archways*, that the footway arch is to be made a little to the weſt of the *London-Dock* entrance, and the carriage-way arch at the ancient horſe-ferry between Limehouſe and Rotherhithe. On inquiry, we have been told, that the preſent ſcheme is, to ſink a ſhaft on one ſhore of the *Thames*, with an engine thereon and pumps, and to continue the ſame to a ſufficient depth, at which to begin the tunnel in oppoſite directions, riſing to the oppoſite ſhore of the river one way, and to a point ſufficiently inland the other way, for a regular and proper aſcent for carriages. We can hardly ſuppoſe that this matter has proceeded thus far, without its being aſcertained, by a ſeries of borings, quite acroſs the river, at ſhort diſtances from each other, that there is no fiſſure or crack in the clay, beneath the alluvial matters, which may be filled up with quickſand or other looſe ſoil impracticable to tunnel through, under the bed of a river: but, if we admit the whole matter to be ſolid clay under the water-way or bed of the river, yet the number of houſes which muſt be pulled down, or endangered, oppoſite to the tunnel, in this way of conducting the buſineſs, in order to bring the archway to the ſurface on one ſide of the river, and the inconvenient diſtance which that entrance will be from the water-ſide, are almoſt inſuperable objections to its adoption. We have no doubt of the practicability of forming as many arch-ways under the *Thames* as may be wanted (if money is not ſpared, and ſcientific and proper men are employed on the work), but are of opinion that for ſuch to ſucceed, the river muſt be piled off, for ſhort lengths at a time, while the neceſſary excavation is made in the bottom for turning a length of the arch, and ſecurely covering it with clay or puddle: and after ſeveral ſucceſſive lengths are thus formed, the water and traffic of the river may be admitted over the part which is completed. Very powerful pumping-engines will be neceſſary, in this or any other way of conducting ſuch a work with the probability of ſucceſs. The *Thames* river, below London, is embanked through a great part of its courſe; the time when theſe banks were firſt erected is uncertain, but they appear to be of great antiquity; and during ſeveral hours of each tide, the adjoining meadows are 10 feet or more below the level of the water. At Dagenham, about 7 miles below Blackwall, a large breach in one of theſe banks happened, which captain *John Perry* ſucceeded in ſtopping, after ſeveral others had failed in their attempts. On the 5th of Auguſt 1776 the plan was firſt adopted of employing *convicts* in ballaſting, and other works for the improvement of the river *Thames*, under Mr. *Duncan Campbell*; theſe men, properly ironed, are lodged in hulks, or old veſſels, off Woolwich, and have principally been employed in enlarging the wharfs at Woolwich Warren, or Royal Arſenal, which work is ſtill proceeding. In the year 1785, and again in 1802, the *London Lynn and Norwich* (or North London) canal was propoſed to join the *Thames* river at Limehouſe. In 1798 a new channel was propoſed to be cut for the *Thames* river ſtraight acroſs the Iſle of Dogs, and dams with ſluices and locks to be made on the old courſe of the river, for converting the ſame, round the iſland by Deptford and Greenwich, into one vaſt floating dock for ſhips! About the ſame time, the *London Docks* were in contemplation, and a canal was propoſed to extend from them to the *Thames* river at Blackwall; the *Iſle of Dogs* canal has ſince been made, and in part anſwered both theſe purpoſes. In 1802 the *Canterbury and St. Nicholas-Bay* canal was propoſed to join the *Thames* at the latter place; and in the ſame year the *London and Waltham-Abbey* canal was intended to join at Bell-wharf in Shadwell. The *Thames and Medway* proprietors pay 1s. annually as an acknowledgment to the city of London, as conſervators of the *Thames* river, for the liberty of connecting therewith.

Thames River (*middle part*). Acts 14 and 17 Geo. III. —The general direction of this part of the Thames river is nearly weſt, by a very crooked courſe of 37 miles between the counties of Surrey and Middleſex; the tide flows through the firſt $16\frac{1}{2}$ miles thereof to Richmond bridge: its objects are the ſupply of London, and the immenſe trade which is carried on with the rivers and canals weſtward: at Vauxhall creek it is joined by the *Grand Surry* canal; at Wandſworth entrance-baſon, the *Surry Iron Rail-way* joins; at Brentford Creek the *Grand Junction* canal joins, and at Ham Haw, near Shepperton, the *Wey* river joins (2 miles from the junction with the *Baſingſtoke* canal). London, the firſt Britiſh town, has 864,845 perſons; Wandſworth, Brentford, Kingſton, Chertſey, and Staines are alſo conſiderable towns on this part of the *Thames* navigation; which commences in the *Thames* lower part at London bridge, and terminates in the *Thames and Iſis* navigation at London-ſtone, at the extremity of Middleſex county, about ½ a mile above Staines bridge; from near Chelſea, Pimlico creek extends for about ¾ of a mile to Chelſea water-works engine. From low-water at Richmond bridge to London-ſtone, 20½ miles, is a riſe of 36 feet; ſee a ſection thereof in *Gentleman's Mag. March*, 1771, and in *Zachary Allnutt's Conſiderations on the Thames River*, 1805, wherein it appears, that the navigation hereon is in two or three places interrupted by ſhallows, not exceeding 2 feet 9 inches depth of water in ordinary times. At Laleham, Mr. *John Rennie* gauged the ſtream of this river, in the dry ſeaſon of 1794, and found 1155 cubic feet of water per ſecond to be then paſſing down. The corporation of the city of London, as conſervators of the river *Thames*, and by the 17 of Geo. III. above, were unauthoriſed to make any new ſide-cut by this part of the river, or to erect any weir quite acroſs the channel of the river; and their exertions for the improvement of this navigation, ſo much in need of amendment, have been confined to the erecting of jetties and weir-hedges, for contracting the breadth of the ſtream in many of the ſhallow places, to the dredging or ballaſting of others, to deepen the channel, and to the eſtabliſhing of regular fluſhes of water, twice a week, or oftener, from the pounds and mill-dams in the upper part of the river, for enabling barges, during the run of ſuch fluſhes, to paſs the ſhallow places; except, that they have completed a good horſe towing-path through the whole length of this navigation, beginning at Putney bridge, on the ſouth ſhore of the river: immenſe ſums of money (upwards of 1400l. per annum) having been expended on the above inefficient meaſures, and yet the navigation in all dry ſeaſons continues intolerably bad, and alſo frequently interrupted and rendered dangerous by floods. We are happy to obſerve, that notices were given in September laſt (1805) for an act to authoriſe the making of weirs acroſs the river, and ſide-cuts and locks, in the pariſhes of Laleham, Littleton, Shepperton, Sunbury, Chertſey, and Thorpe. The above act (17 Geo. III.) authoriſed the city of London to purchaſe certain local tolls on the navigation between Staines and Richmond, and to levy 4d. per ton per voyage up and down, for the above purpoſes; they have a commodious barge ſtationed on the river for the reſidence of a collector of this toll, and an annual account of all the receipts and diſburſements under this act is preſented to parliament. The *Grand Surry* canal was (by its act 41 Geo. III.) required to pay 2 guineas as a fine, and a rent of 60l. annually, for the liberty of connecting with this navigation; and the *Croydon* canal 40l. per annum; the *Surry Iron Rail-way* is to pay 10l. per annum; and the *Grand Junction* company are to pay 600l. per annum, and a toll of ½d. per ton on all goods which paſs into or out of this canal. Among the bridges upon this navigation, *London Bridge*, at its commencement, built of ſtone in 1209, comes firſt to be noticed: the river at this place is about 900 feet wide, the bridge, which is 60 feet high and 74 feet wide, conſiſts of 19 arches, the middle one of which is 72 feet wide, but the next thereto on each ſide are narrow ones, and no regular order is to be obſerved in the arrangement of the arches, which are moſt of them of different widths, under 20 feet; the piers between them are immenſely thick, being alſo ſurrounded with ſtarlings or vaſt frames of piling and croſs beams of timber, intended for the protection of the foundations of the bridge: previous to the making of the large lock or centre arch, in 1756 (by the removing of a pier and its ſtarling, and turning one large arch inſtead of two) the clear water-way between all the ſtarlings amounted but to 194 feet, and above the ſtarlings (which are covered when the tide has riſen about two thirds of its uſual height) the water-way amounted to only 450 feet, or half the width of the river; a further obſtruction alſo ariſes from the water-wheels, which are fixed on the upper ſide of the bridge at both of its ends, oppoſite to ſeveral of the arches, for pumping up water for the ſupply of the city of London and Borough of Southwark. By theſe contractions of the water-way, a fall and current is occaſioned under this bridge, which for ſeveral hours of each tide is quite tremendous, and proves a moſt ſerious obſtacle to navigation, as well of danger to the bridge itſelf. If Mr. *John Smeaton*'s advice had not been quickly followed, in 1756, in returning and throwing in the ſtones, which had been recently taken up from the old middle pier, together with many cargoes of other large and rough ſtones, the adjoining ſtarlings and piers of the great lock would certainly have been undermined, and the bridge have fallen: great quantities of chalk and Kentiſh rag-ſtones are now annually brought and depoſited within the piling of the ſtarlings, and between them, at the time they are repaired; a work for ever requiring to be done, in ſome part or other, of theſe clumſy obſtructions to the waters and to navigation: immenſely deep gulphs are formed at each ſide of the bridge by the pitch or fall of the water, and the ſoil and rubbiſh excavated therefrom is continually thrown up at a diſtance, ſo as to form large banks dry at low-water, in ſpite of a continual dredging or ballaſt-heaving, which is reſorted to for removing them. Theſe inconveniences, which had been long and loudly complained of, occaſioned, about the year 1799, a propoſal, for pulling down this bridge, and ſubſtituting two ſtone bridges, with capacious arches: theſe were to be placed near to each other and to connect at their ends; the centre arch of each was to have a draw-bridge, for admitting ſhips up the river, as far as Blackfriars bridge; the intention of the two bridges being, that one of the drawbridges might always be ſhut down for the paſſage of carriages and perſons, while ſhips might be paſſing through the other into or out of the baſon between the bridges. Another propoſal was, to conſtruct a caſt-iron bridge of one ſingle arch of 600 feet ſpan and with 65 feet clear opening above high water; as we have already mentioned: theſe, and other projects for the ſame purpoſe were minutely and carefully examined by a ſelect committee of the houſe of commons, and their reports, together with views of the different propoſed bridges, have been ſince publiſhed, and a propoſal made for a caſt-iron bridge of three arches, reſting on ſtone piers, the centre arch 65 feet high for the paſſage of ſhips; in September 1802, the city of London gave notices of their intention to apply for an act of parliament for removing London bridge and building another, but nothing further, we believe, has ſince been done. *Blackfriars Bridge* is an elegant ſtone ſtructure, offering ſcarcely the leaſt impediment to the navigation; it was built in 1770, by Mr. *Robert Milne*; the river in this place is 995 feet wide, it has 9 large elliptical arches, the centre one 100 feet wide, the others regularly diminiſhing to the outſide ones which are 70 feet each. The whole coſt of this bridge, in the 10¾ years during which it was in hand, was 150,840*l.* *Weſtminſter Bridge* was built of ſtone in the year 1750; the river in this place is 1220 feet wide; there are 17 large, and two ſmall ſemi-circular arches in this bridge, the centre one 76 feet wide, the others diminiſhing by 4 feet each in width, to the ſmall ones at the ſides; the coſt of this bridge and its avenues was 389,500l., and it was about 10 years in hand. At Batterſea and at Putney there are narrow, low, and inconvenient wooden bridges over this fine river. On the 4th of June 1783, a handſome and convenient ſtone bridge was begun over this river at Kew, and in the year 1774, another ſtone bridge was begun at Richmond. About the year 1801, a new ſtone bridge was built over this river at Staines, but it was ſhortly after obliged to be taken down, owing to a ſettlement therein; an iron bridge was next ſubſtituted, and opened on the 3d of September, 1803, of one arch, with 180 feet ſpan, riſing only 16 feet above the ſtone abutments on which it reſted; but this, we are ſorry to add, has lately ſuffered the fate of the other, and has neceſſarily been taken down, a circumſtance the more to be regretted, as this was the firſt caſt-iron bridge brought into uſe in this part of the kingdom. At Walton, there is a curious bridge, conſiſting of a large wooden opening, and ſmaller brick arches on each ſide of it. It may be proper to add, that the intention has very recently been announced, of building a new ſtone bridge over this river from Vauxhall to Millbank, with a new road over the ſame from Vauxhall turnpike acroſs Tothill fields to Pimlico. In the year 1770, and again in 1794, the *Maidenhead and Iſleworth* canal was propoſed to join this river at Iſleworth and at Bolter's Lock, or Taplow mill; in 1792, the *Hampton Gay and Iſleworth* was propoſed to join at the latter place; in 1801, the *Leatherhead and Thames* rail-way was propoſed to join this river at Weſt Moulſey, and an extenſion of the Grand Surry canal was intended to Kingſton; in 1802, a cut from the propoſed weſtern branch of the *Grand Junction* canal was propoſed to join at Ham Haw oppoſite to the *Wey* river; and, in 1803, the *Portſmouth and London* rail-way was propoſed, to terminate in Stamford ſtreet, near Blackfriars bridge.

THAMES AND ISIS NAVIGATION. Act 11, 15, 28, and 35 of Geo. III.—The general direction of this navigation is nearly N. W. by a very ſerpentine and crooked courſe of about 110 miles between the counties of Surrey and Berks, and of Bucks, Oxford, and Glouceſter: its weſtern end is conſiderably elevated; its objects are the ſupply of London and the carriage of coals, and a variety of other articles: near Reading it connects with the *Kennet* river; at Abingdon, the *Wilts and Berks* canal joins this navigation: at Badcock's garden in Oxford, this navigation is joined by the *Oxford* canal, and at Godſtow, by the *duke of Marlborough*'s cut from the ſame canal. Oxford is the 38th Britiſh town, with a population of 11,694 perſons, and Reading is the 55th, with 9,742 perſons; Staines, Windſor, Maidenhead, Great-Marlow, Henley, Wallingford, Abingdon, and Lechlade, are alſo conſiderable towns on this navigation, which commences in the *Thames* middle part at London-Stone near Staines, and terminates in the *Thames and Severn* canal at Lechlade. From Staines-ſtone to the water above Bolter's Lock, 15½ miles, is a riſe of 34 feet: thence to the entrance of the *Kennet* river 24½ miles, has a riſe of 27½ feet, beſides the riſe at the weirs; thence to the termination to the *Thames* and beginning of the *Iſis* river, is about 23 miles; thence to the *Wilts and Berks* canal about 10 miles; thence to the *Oxford* canal about 8 miles, and thence to Cricklade about 29 miles. The Gentlemen of the counties adjoining this navigation are Commiſſioners for executing, in different diſtricts, the above acts; they have borrowed 60,800l. and have expended the ſame, over and above the ſurplus of the tolls, in making 24 ſide-cuts with opening weirs and pound-locks, with a horſe towing-path, and other works for improving this navigation, which is now accompliſhed, ſo that very long and wide barges drawing 3 feet 10 inches, can in general paſs the ſame; the rate of tonnage is only ¼ per ton per mile; and an account of the receipts and expenditure on this concern is annually preſented to parliament. In 1796, the receipts amounted to 9,839l. in 1801, to 10,066l. in 1802, to 7,173l. Mr. *Zachary Allnutt* is engineer to the 2d and 3d diſtrict of this navigation. In the year 1800, Mr. *Wilſon* prepared a deſign and model for his Majeſty, of a caſt-iron bridge, of one arch, propoſed to be erected over the *Thames* at Datchet. In the year 1770, the *Reading and Maidenhead* canal was propoſed to join this navigation at Sunning, and at Bolter's lock; in 1802, a weſtern branch of the *Grand Junction* canal was propoſed to join this navigation at Harleyford near Great Marlow, and croſſing the ſame at that place, it was to proceed to join it again near Reading; and in the ſame year another branch from the *Grand Junction*, through Ayleſbury, was propoſed to join this navigation near to Abingdon, and to the *Wilts and Berks* canal.

*Thames and Avon Canal.* In the reign of Charles II., Mr. *Joſeph Moxon* was employed to ſurvey the line for a canal, and a bill was prepared and brought into parliament, from the *Thames and Iſis* navigation at Lechlade, by Cricklade, Malmſbury, Chippenham, and thence by the courſe of the *Avon* river to Bath, 40 miles in length: in 1754, this deſign was again revived, with the idea of employing the ſoldiers upon it; and it was ſtated that a canal 50 feet wide at top, 30 at bottom, and 4 feet deep, might thus be completed for 1000l. per mile.

THAMES AND MEDWAY CANAL. Act 40 and 44 of Geo. III.—The general direction of this canal is S.E. for 8½ miles in the county of Kent; it is level with the ordinary high tides in the river Thames: its object is for ſhortening the voyage of barges from Graveſend to Chatham round by the Nore; Chatham is the 46th Britiſh town, with a population of 10,505 perſons, and Rocheſter the 90th, with 6,817 perſons; Graveſend is alſo a conſiderable town near this canal, which commences in the *Thames* river at Graveſend, and terminates in the *Medway* river at Nicholſon's ſhip-yard in Friendſbury, with a cut from Whitewall on the line of this canal to the *Medway* at Strood, oppoſite to Chatham royal dock-yard. Tide-locks and entrance baſons are to be made at each of the three terminations of this canal; Mr. *Ralph Dodd* was the projector of this canal, on which Mr. *John Rennie* and Mr. *Ralph Walker* have ſince been employed. In December 1801, this canal was completed from Graveſend to Denton. The company were authoriſed to raiſe by the firſt act 60,000l. in 100l. ſhares, and a further ſum by the laſt act, and they are to pay 1s. annually to the city of London as conſervators of the *Thames* river, for the liberty of connecting therewith, and 1s. to the corporation of Rocheſter, as conſervators of the *Medway*, for the ſame privilege.

THAMES AND SEVERN CANAL. Act 23, 31, and 36 of Geo III.—The general direction of this canal is Eaſt, for 30½ miles in the counties of Glouceſter and Wilts: it croſſes the Grand Ridge by a tunnel; its objects are a communication between the Severn and Thames rivers, the ſupply of the country through which it paſſes with coals, deals, &c. and the export of farming products. Stroud is the 114th Britiſh town, with a population of 5,422 perſons; Minchinghampton, Cirenceſter, Cricklade, and Lechlade, are alſo conſiderable towns on or near to this canal; which commences

mences in the *Stroudwater* canal at Wallbridge near Stroud, and terminates in the *Thames and Iſis* navigation at Lechlade: it has a branch of about 1 mile in length to the town of Cirenceſter. From the *Stroudwater* canal to Sapperton or Salperton, $7\frac{3}{8}$ miles, is a riſe of 243 feet by 28 locks; thence, the ſummit pound continues through the Tunnel, $2\frac{3}{8}$ miles, to near Coates, and level; thence, to the *Thames and Iſis* navigation, $20\frac{3}{8}$ miles, is a fall of 134 feet by 14 locks. The firſt 4 miles of this canal from Stroud to Brinſcome-port Baſon, is of the ſame width and depth as the *Stroudwater* canal, and is navigated by the *Severn* boats; the remainder of the line is 42 feet wide at top, 30 at bottom, and 5 feet deep; at Brinſcombe-port, goods going eaſtward are removed into barges 80 feet long and 12 wide, which carry 70 tons each. The famous tunnel on this canal at Sapperton, is 4300 yards long, the arch being 15 feet wide in the clear, and 250 feet beneath the higheſt point of the hill, which proved to be hard rock, much of which required blaſting, and ſome of it was ſo ſolid as to need no arch of maſonry to ſupport it; the other parts are arched above, and have inverted arches in the bottom; the coſt of excavating this tunnel, in 1788, amounted to 8 guineas per cubic yard. The ſummit level of this canal is ſupplied by a feeder brought through lord Bathurſt's gardens. Mr. *Robert Whitworth* and Mr. *Joſeph Clowes*, were the engineers. On the 20th of April, 1789, the Sapperton tunnel was finiſhed, and on the 19th of November of the ſame year, the whole line was completed and opened. We are ſorry to have heard it remarked, that this canal has been conducted through porous gravelly ſoils, when a line for the ſame, equally convenient, might have made the cutting fall in a clay ſoil, and that puddling has been in too many inſtances neglected or has failed, by which the canal is rendered ſhort of water, and the land and mills have been greatly injured: fanciful round buildings like towers have been made in different places on this canal, for the reſidence of the lock-keepers. This company were authoriſed to raiſe 255,000l., the ſhares being 100l. each; there was a proviſion that 3 per cent. intereſt ſhould be paid (out of the principal) to the ſubſcribers on their ſhares, until the canal was completed and opened; we have heard that the preſent profits are not much above 1 per cent. No ſtamps were neceſſary to the proceedings of this company. The rates of tonnage and the regulations thereof with the *Stroudwater* company, are very long. See *Phillips*'s 4to. *Hiſtory*, pages 222 to 225. Manures for the adjoining lands are to paſs toll free: leſs than 6 tons not to paſs the locks without paying for that weight; $\frac{1}{2}$ mile-ſtones to be erected. In 1799, this company offered bounties for introducing the coals brought by their canal to the weſtern parts of Oxford and Berk ſhires. The *Glouceſter and Berkley* company are to compenſate this company, in caſe the conſtruction or repair of their works interrupts at any time the communication with the *Severn*. In September 1800, it was intended to make from near Ingleſham a forked branch paſſing Faringdon and Highworth, to connect with the *Wilts and Berks* canal in two places.

THANET'S CANAL. Act 13 Geo. III.—The direction of this canal is nearly N.E. for about $\frac{1}{2}$ of a mile in length, in the Weſt Riding of Yorkſhire; it is conſiderably elevated, near to Skipton, which is a conſiderable town; it commences in the *Leeds and Liverpool* canal, near Skipton, and terminates at Skipton-caſtle, lime-ſtone quarries. It was cut at the private expence of the *earl of Thanet*, through whoſe eſtate alone it paſſes, except one cloſe: its object is to convey coals to the lime-kilns, and to export lime as a manure and for building.

THYRN AND BURE NAVIGATION. The general direction of theſe rivers is about N.W. for nearly 30 miles in the county of Norfolk: they are not greatly elevated above the ſea in any part: the objects are the import of coals, deals, &c. and the export of farming products. Yarmouth is the 27th Britiſh town, with a population of 14,845 perſons; Ayleſham is alſo a conſiderable town on this navigation, which commences in the *Yare* river Yarmouth, and terminates at the town of Ayleſham: it has branches from near Thurne and Horning, through the fens and broads, to Hickling and Dilham, about 8 and 10 miles in length.

TIEV RIVER. This river, (ſometimes called the Tivey or Teifi river,) has nearly an eaſt courſe for about 39 miles, between the counties of Cardigan and Pembroke, and Caermarthen in South Wales: its eaſtern end is conſiderably elevated: its objects are the ſupply of Llanbedr and Cardigan, and the export of agricultural products. Cardigan, Kilgerran, Newcaſtle-in-Emlyn, and Llanbedr, are conſiderable town on this river, which commences in the tide-way in St. George's channel, and terminates at Llanbedr, or Lampeter.

TONE AND PARRET NAVIGATION. Acts 10 and 11 William III. 6 Anne, and 44 Geo. III.—The general direction of this navigation is nearly ſouth, by a bending courſe of about 27 miles in the county of Somerſet: its ſouthern end is conſiderably elevated: its objects are the import of coals, and the export of agricultural products; at Borough chapel it is joined by the *Parret* river. Taunton is the 106th Britiſh town, with a population of 5,794 perſons. Bridgewater is alſo a conſiderable town on this navigation, which commences in the tide-way in Brigewater-bay, at Start point, in the Briſtol channel, and terminates in the *Grand Weſtern* canal at the town of Taunton. In September 1798, a caſt iron bridge was completed, conſiſting of one arch of 75 feet ſpan over the *Parret* river at Bridgewater, at the expence of 4000l. (See our article BRIDGE). It was erected in the place of a ſtone bridge, ſaid to have been built about the year 1300. In 1796, the *Briſtol and Taunton* canal was propoſed to connect with this navigation at Bridgewater.

*Topcliff and Pierſe-Bridge.* In June 1801, it was propoſed to form a canal from the *Swale* river at Topcliff to Pierſe-bridge on the Tees river: the intention of this canal was for ſupplying the north riding of Yorkſhire with Durham coals.

TORRIDGE RIVER. The direction of this river is ſouth for three miles, near to the north-weſt coaſt of Devonſhire: the tide flows through its whole length: it commences in the *Taw* river near Appledore, and terminates at Biddeford bridge: its object are the ſupply of Biddeford, a conſiderable town, with coals, &c. and the export of agricultural products. The ſpring tides riſe 18 feet at Biddeford.

TOVEY RIVER. The direction of this river, (ſometimes called the Towey), is north, for about $8\frac{1}{2}$ miles, in Caermarthenſhire in South Wales: the tide flows through its whole length: its object is the ſupply of Caermarthen, which is the 113th Britiſh town, with a population of 5,548 perſons: it commences in the Briſtol channel, at St. Iſhmael's, and terminates at Caermarthen bridge. In September 1804, it was intended to apply for an act to improve the port, quays, and dock at Caermarthen.

TRENT RIVER, (*lower part*). Act 34 Geo. III.—The general direction of this navigation is nearly S.S.W. by a bending and crooked courſe of about 116 miles, ſkirting Yorkſhire for a ſhort diſtance, and through the counties of Lincoln and Nottingham, and between thoſe of Leiceſter and Derby: it is not greatly elevated in any part: its navigation is of vaſt importance to the country, owing to the many communications which it forms with other rivers or canals: at Keadby it connects with the *Stainsforth and Keadby* canal; at Stockwith, with the *Idle* river, and near the ſame place with the *Cheſterfield* canal; at Torkſey, with the *Foſs-dyke* canal; at Crankleys, in South-Muſkham, with the *Dean* river; at Trent-bridge, near Holme-pierpoint, with the *Grantham* canal, and the *Nottingham* canal; near Sawley, with the *Loughborough* navigation, or Soar river, and the *Erewaſh* canal. Nottingham is the 17th Britiſh town, with a population of 28,801 perſons; and Newark is the 91ſt, with 6,730 perſons. Burton-upon-Strather, Gainſborough, Newark, Southwell, and Bingham, are alſo conſiderable towns near this navigation; which commences in the *Humber* river at Trent-fall, (at the junction of *Ouſe* river, and *Market Weighton* canal,) and terminates in the Upper *Trent* river at Sawley-ferry, at the junction of *Derwent* river, and the *Trent and Merſey* canal. It has a ſide-cut of 10 miles in length, made in purſuance of the above act, for avoiding 21 ſhoals, and 2 bridges, which occur in 13 miles of the river between Trent bridge, at the commencement of the *Nottingham* canal, and Sawley ferry, at the commencement of the *Trent and Merſey* canal. This cut (ſometimes called *Trent Canal*), has a riſe of 28 feet, and it croſſes and connects with the *Erewaſh* canal near Sawley; it has alſo a ſhort cut and lock into the *Trent* in Beeſton. The lower part of this river is through fens, and is embanked on both ſides: it is ſubject to very great floods: the tide flows to Gainſborough, ſo that ſmall veſſels can come up to that place; but between this and Wilden-ferry, a great number of ſhallows occur, owing, in a great meaſure, to the too great width of the river: Mr. *John Smeaton*, who examined it in 1761, ſtates, that in ſeveral places in the common ſtate of the river, in dry ſeaſons, there was not above 8 inches depth of water; that at ſuch times, without the aid of fluſhes from King's mills upon this river, and the loweſt mills upon the *Derwent*, navigation was impracticable, The 33 of Geo. III. for *Grantham* canal required the proprietors of this navigation to deepen the bed of their river, ſo that there ſhall always be 30 inches deep of water in the drieſt ſeaſons for boats to paſs between the *Grantham* and the *Nottingham* canals, and by which they may alſo now paſs into the *Trent Canal*, for avoiding the ſhallows above Nottingham. An act was paſſed a few years ago for building a new bridge over this river at Gainſborough. In 1801 a new ſtone bridge was intended at Gunthorpe-ford. In the year 1789 and 1790, ſeveral acres of land were gained from the wide muddy banks of this river, ſimply by ſtaking down rows of furzen faggots thereon, to check the current, and encourage the abundant depoſit which this river makes, wherever its waters become ſtationary; (ſee *Agricultural Magazine*, vol. vii. p. 98.) a circumſtance which proves of immenſe advantage in many inſtances, by the warping of land near this river in floody times, to improve it. The flood which happened in the beginning of 1800, forced a new and much ſtraighter courſe for this river below Gainſborough, and occaſioned the old crooked channel to be deſerted. For making the new ſide-cut, or Trent canal, this company were authoriſed to raiſe 23,000l. in 50l. ſhares: and they are allowed to collect a variety of tolls on different parts of this cut and the river. See *Phillips*'s 4to. *Hiſtory*, *App.* pages 169 and 170. But theſe were not to take place until 13,000l. had been expended under the above act, which embraces the improvement of the river, ſo that there may be always 30 inches deep of water, the making of horſe towing-paths, purchaſing the Nottingham hauling-machine, or capſtern, &c. The profits of the Trent canal are not to exceed 7 per cent. By the 33 Geo. III. for *Derby* canal, only half the uſual rates are to be charged on goods paſſing only the [illegible] on this river, in their way to or from that canal: and by 33 Geo. III. for *Grantham* canal, this company are to receive [illegible] per ton for lime, and 3d. per ton for all other goods, (except road-materials and manures), which croſs this river, when deepened as above, between the *Grantham* and *Nottingham* canals. In 1766, the *Wilden and Kings-Bromley*, and in 1765, the *Ternbridge and Winsford* canals were propoſed to join this river at Wilden ferry, where the *Trent and Merſey* canal now joins.

TRENT RIVER, (*upper part*). Acts 10 and 11 William III.—The general direction of this navigation is nearly W.S.W. by a crooked courſe of about 19 miles, in Derbyſhire and Staffordſhire, and ſkirting Leiceſterſhire: it is not very greatly elevated above the ſea, in any part: its objects are the carriage of coals, and the export of ſalt, gypſum, earthen-ware, ale, and agricultural products: it connects at Swarkſtone with the *Derby* canal, and has the *Trent and Merſey* canal running the whole length almoſt by its ſide, and communicating with it at its two extremities. Burton-upon-Trent is the only conſiderable town on this navigation; which commences in the lower *Trent* navigation at Wilden Ferry (at the commencement of the *Derwent* river and *Trent and Merſey* canal,) and terminates near Burton, at a branch from the *Trent and Merſey* canal. The *earl of Uxbridge* is the ſole proprietor of this navigation, and all other perſons are reſtricted from erecting or uſing wharfs or warehouſes on its banks without his ſpecial conſent. The earl or his leſſees are entitled to 3d. per ton, on goods navigated on any part of this navigation; which was ſaid, in 1765, to be unimproved, except by the erection of locks at two different mill-weirs; and, more than 20 ſhallows then exiſted, over which boats could not paſs in dry ſeaſons, without fluſhes of water: ſtrange ſtories were at that time related of the conduct of theſe leſſees, and inſinuations were made, that a barge loaded with ſtones was ſunk by deſign in Kings-mill lock, and which lay there almoſt 9 years, and obliged all goods to be unloaded into freſh boats at that place! happily the rivalry of the canal by its ſide, renders ſuch an occurence hereafter unlikely ever to happen. The bridge over this river at Burton-upon-Trent is ſaid to be the longeſt in England, being 1545 feet long, with 34 arches. It may be proper here to remark, that Mr. *Smeaton*, in 1768, recommended the making of a long bridge or water-road adjoining the lower part of this river, between Muſkham and Newark, that ſhould have 300 yards long of clear water-way through its 72 arches! In 1793, the *Bredon* rail-way was propoſed to join this navigation at Weſton Cliff; in 1796, the *Commercial* canal, and in 1797, an extenſion of the *Aſhby-de-la-Zouch* canal was propoſed to connect herewith at Burton.

TRENT AND MERSEY CANAL. Acts 6, 10, 15, 16, 23, 25, *two of* 37, and 42 Geo. III.—This canal (ſometimes called the *Grand Trunk*, or the Staffordſhire canal,) has its general direction about E.S.E. by a very bending courſe of 93 miles in the counties of Cheſter, Stafford, and Derby: it croſſes the grand-ridge by a tunnel: its objects are the export of coals, ſalt, pottery-wares, lime, gypſum, Swithland-ſlates, agricultural products, &c. and forming parts of the grand inland communications between Liverpool and Mancheſter, with Hull, Briſtol, and London; at Quiton's-wood in Stoke, it connects with the *Newcaſtle-under-line* canal: at Great Haywood with the *Stafford and Worceſter* canal; at Fradley Heath with the detached part of *Coventry* canal; and at Swarkſtone it croſſes and connects with the *Derby* canal. Although none of the towns on this long canal appear to have ſo many as 5000 inhabitants, yet

Northwich, Middlewich, Sandbach, Newcaſtle-under-line, Stone, Stafford, Rudgley, Litchfield, and Burton-upon-Trent, on or near to the ſame, are conſiderable places. The commencement of this canal is in *Bridgewater*'s canal at Preſton-brook, and its termination in the *Trent* lower navigation, at Wilden-ferry near Shardlow, the point of junction of the *Trent* canal, or ſide-cut, the upper *Trent* navigation, and the *Derwent* river: from Etruria, a principal branch (ſometimes called the *Caldon Canal*,) proceeds by Froghall to Uttoxeter, by a very bending courſe of about 28 miles in length; from this, at Froghall in Kingſley, there is a rail-way branch of $3\frac{1}{4}$ miles to Caldon-low lime works, alſo from Stanley Moſs in Endon there is a canal branch of about $3\frac{1}{2}$ miles to the town of Leek, and from Shelton, a ſhort cut to Cobridge: from Stoke-upon-Trent there is a rail-way branch to Lane-end; and from Etruria another to Handley-green; from Longport to Dale-hall there is a canal-branch, and the ſame is continued forwards by a rail-way to the potteries at Burſlem; there is a cut 1 mile in length to the *Trent* river near Burton. Near Lane-delph, and in Harecaſtle there are ſhort cuts or tunnels, extending to the pits or ſeams of coals. From *Bridgewater*'s canal to Middlewich, 18 miles, is a level; thence to near Talk, 11 miles, is a riſe of 326 feet by 35 locks; thence along the ſummit-pound, and through Harecaſtle tunnel to the Caldon branch at Etruria, 6 miles, is level; thence to the *Stafford and Worceſter* canal at Great Haywood, 17 miles, is a fall of about 150 feet and 19 locks; thence to the *Coventry* canal at Fradley Heath, 13 miles, is about 32 feet, and 4 locks; thence to Horninglow wharf, 12 miles, is about 86 feet fall, and 11 locks; thence to the *Derby* canal at Swarktone, 10 miles, is about 16 feet fall, and 2 locks, and thence to the *Trent* river at Wilden-ferry, 6 miles, is a fall of about 32 feet, and 4 locks. From the ſummit level of the line at Etruria to near Bagnal on the Caldon branch, $5\frac{3}{4}$ miles, is a riſe of 75 feet, by 7 locks; thence to Stanley-Moſs, 1 mile, is level; thence to Froghall, $9\frac{3}{4}$ miles, is a fall of 61 feet, by 9 locks. From Preſton-brook to Middlewich, at the weſtern end, and from Wilden-Ferry to Horninglow near Burton, at the eaſtern end, the width of the canal at top is 31 feet, at bottom 18, and it is $5\frac{1}{2}$ feet deep; the locks here are 14 feet wide, adapted to river barges of 40 tons burthen; the middle part of the canal, and its branches, are 29 feet broad at top, 16 feet at bottom, and it is $4\frac{1}{2}$ feet deep, the locks being only 7 feet wide; the boats are 80 feet long, 6 feet wide, and carry 18 to 20 tons of lading. There are 16 public wharfs on this canal with warehouſes, cranes, weighing-engines, and other neceſſary conveniences at each. Over this canal there are 258 road and foot bridges, and under it 3 large aqueducts, and 124 leſſer ones and culverts. Through Harecaſtle Hill is a tunnel of 2888 yards in length, and upwards of 70 yards below the hill; this tunnel interſects, and has croſs branches to, ſeveral veins of coals in the hill, and is alſo famous for being the firſt public canal-tunnel conſtructed in England; the driving of this tunnel, in 1776, coſt about 70s. 8d. per yard run: the height of the arch is 12 feet, and its width 9 feet withinſide. At Preſton-on-the-hill near Bridgewater's canal is another tunnel of 1241 yards in length; at Barton in Great Budworth is another, 572 yards long; at Saltersford, or Saltersfield, in the ſame pariſh, is another of 350 yards long, and there is a fifth tunnel at Armitage, or Hermitage, of 130 yards in length; the heights of theſe laſt tunnels are $17\frac{1}{3}$, and their width $13\frac{1}{2}$ feet. At Monks-bridge there is an embankment 13 feet high of $1\frac{1}{4}$ mile in length, and an aqueduct bridge over the Dove river of 23 arches, from 15 to 12 feet wide each. At Alrewas is an aqueduct over the Trent river, with 6 arches of 21 feet ſpan; and near Middlewich is another aqueduct over the Dane, with 3 arches of 20 feet ſpan. In the Rudyerd vale, N.W. of Leek, near the grand-ridge, is a reſervoir of 160 acres extent, with an artificial head 30 feet in height; from this a feeder conducts its water to the Leek branch, and thence into the ſummit pounds of the Caldon branch, and of the main line: there are four ſmaller reſervoirs near the ſummit, which meaſure together 60 acres; all waters within 5 miles of the line are allowed for the uſe of this canal. The rail-way branch to Mr. *Gilbert*'s Caldon lime-works, made about the year 1777 or 1778, was compoſed of caſt-iron bars pinned down upon rails of wood fixed acroſs wooden ſleepers, as we have before deſcribed; it appears to have been ſet out, before the true principles of this excellent mode of conveyance were ſo well underſtood as at preſent, being very crooked and with frequent variations in the angle of its aſcent; in the laſt of the above acts, there is a proviſion made for varying the line of, and improving this rail-way. It is ſaid to have coſt, at firſt, about 1760l. per mile; in 1794, one horſe, we are told, for 9 months in the year, made in each week three journeys on four of the days, and two journeys on the other two days, hauling 3 tons 6 cwt. of limeſtone down each journey, from the quarries at Caldon to Froghall wharf; for forwarding this ſtone to the canal at Etruria, the company found boats, the bargeman found his own horſe and boy, towing lines, &c. and delivered the ſtone at 9d. per ton, the diſtance being about $16\frac{1}{2}$ miles. Mr. *James Brindley*, Mr. *John Smeaton*, and Mr. *Hugh Henſhall* were the engineers employed or conſulted on the works of this canal, which were begun in July 1766; in April, 1773, the line eaſtward of Harecaſtle tunnel was completed, and in May, 1777, the whole line was completed and opened: the Leek branch, the extenſion of the Caldon branch to Uttoxeter, and the Cobridge branch have been undertaken ſince the year 1797; the Lane-end, Handley-green, and Burſlem branches were projected in 1802. The firſt act above included 6 miles of the weſt end of *Bridgewater*'s canal, but with a power to aſſign or make over the ſame to the duke of Bridgewater, which was accordingly done; the 6th act above aſſigned 11 miles of the *Coventry* line, between Fradley-heath and Fazeley, to this company, who completed the ſame, and then ſold it in equal moieties to the *Coventry* and the *Birmingham and Fazeley* companies, as before mentioned. This company have been authoriſed at different times to raiſe 334,250l. the amount of their ſhares was 200l. each, until 42 Geo. III., when a diviſion of them was made into 100l. ſhares. The rates of tonnage are $1\frac{1}{2}$d. per ton per mile, with reaſonable wharfage after 24 hours, on all kinds of goods; but paving and road-materials (lime-ſtones excepted,) and manures paſs toll-free on the pounds and through the locks, when water runs waſte over their paddle-weirs. The act 33 Geo. III. for *Derby* Canal, granted ſome rates to this company on goods croſſing this canal or paſſing out of it into the *Trent* by the *Derby* canal; ſee *Phillips*'s 4to. *Hiſtory*, *Appendix*, p. 58 and 59. In the years 1760 and 1765, the *Wilden and Kings-Bromley*, and the *Tern-bridge and Windsford* canals were propoſed through parts of the tract now occupied by this canal: in 1793, the *Sandbach* canal was propoſed to join near that place, and the *Bredon rail-way* was intended to be connected herewith near Weſton-cliff: in 1796, the *Commercial* canal was propoſed, to croſs this canal at Horninglow near Burton, and again near Burſlem; in 1797, an extenſion of the *Aſhby-de-la-Zouch* canal, to join this at Horninglow was propoſed; the deſign of the two laſt propoſals was, an extenſion of the wide canals for 40 ton boats, and with the ſame view a plan was, in 1797, mentioned of widening this canal and its locks, bridges, &c. ſo that wide boats might paſs between Fradley-Heath, and the eaſt-end of Harecaſtle tunnel.

TWEED RIVER. This river ſeems to be navigable but about 1 mile from the ſea to Berwick bridge, between Berwick liberty and a detached part of Durham county. Berwick is the 82d Britiſh town with a population of 7,187 perſons; it has a great trade in ſalmon, which are caught in great quantities in this river, and 40,000 kits of it have been pickled and ſent off from this town in one year; 75 to 80 veſſels are employed in fiſhery, and the trade of this place connected therewith. At Berwick there is a ſtone bridge 947 feet long, with 15 arches over this river. At Kelſo ſeveral miles higher up on this river, a ſtone bridge was, in 1798, waſhed away, and a caſt-iron bridge was propoſed to be erected in its ſtead.

TYNE RIVER. Acts 9 and 10 Henry V., 6 and 7 William III., and 41 Geo. III.—The general direction of this river is nearly W.S.W. by a crooked courſe of about 14 miles between Durham and Northumberland; the tide flows through its whole length; its great object is the export of coals. Newcaſtle-upon-Tyne is the 10th Britiſh town with a population of 36,963 perſons, South Shields is the 65th with 8,108 perſons, and North Shields the 80th with 7,280 perſons; Gateſhead is alſo a conſiderable town near this river, which commences in the North Sea at Tynemouth, and terminates at Blaydon in Winlaton. A very peculiar kind of veſſels, as before mentioned, is in uſe upon this river for carrying coals from the waggon-roads, or rail-ways, and ſtaiths to the ſhips; theſe are called keels, and are limited (by 11 and 15 Geo. III.) to $25\frac{1}{2}$ tons of lading, or 8 Newcaſtle chaldrons of coals. From an humane ſet of Gentlemen reſident upon, and concerned in the trade of this river, originated the idea, and they offered a public reward for the *life-boat*, which Mr. *Greathead* brought to perfection, and firſt tried at the mouth of this river on the 30th of January 1790. (See the article LIFE-BOAT). The coals from the numerous coal-mines near this river were formerly delivered to the colliers or coal-ſhips lying below Newcaſtle bridge by means of the keels, but of late years ſeveral mines have been opened on both ſides of the river, and the rail-ways therefrom are conducted to ſtaiths or ſpouts on the quays, by which means the coals are ſhot at once into the holds of the ſhips. Wooden rail-ways were, ſince about the year 1680, in uſe between the mines and this river, ſome of them of conſiderable length, thoſe to Tanfield-Moor are 10 miles long. In April, 1798, an inclined-plane of 864 yards in length, was opened from Benwell, or Bywell collieries, as before mentioned: in October 1803, a rail-way from Mr. *Temple*'s Jarrow mine (128 fathoms deep) was opened to the river. No leſs than 35 ſorts of coals, or rather the produce of as many pits, are uſually ſhipped from this river for London, amounting to 700,000 chaldrons annually: ſee *Edington's Eſſay*, &c. p. 31. On ſome of theſe mines, immenſely large ſteam-engines are employed; in 1763, a new engine was erected at Walker colliery, with a cylinder 74 inches diameter and $10\frac{1}{2}$ feet long, which weighed $6\frac{1}{2}$ tons, and was calculated to lift 307cwt. of water by each ſtroke of its pump. There is an ancient ſtone bridge of 9 arches over this river, which was greatly damaged by a flood in 1771; in the year 1801, it was ſuggeſted to remove as many of its piers as would form a 144 feet opening near the ſouth bank, and to conſtruct an iron arch over the ſame, high enough for the keels to paſs without lowering their maſts. The conſervators of this river, in purſuance of the laſt of the above acts, have deepened and improved the ſame and its quays; in 1801, a new dry, or graving-dock, was opened at South Shields, capable of receiving ſhips at neap tides; in 1802, an act paſſed for building a new light-houſe at Tynemouth with reverberating lamps, inſtead of a coal fire blown by bellows, before uſed. In the year 1798, it was propoſed to make a tunnel or road-arch under the *Tyne* river from North to South Shields for the paſſage of carriages and paſſengers, and the expence thereof was eſtimated at 6,993l. In 1795, the *Newcaſtle and Carliſle* canal was propoſed to join this river near Newcaſtle; in 1796, the *Newcaſtle and Haydon bridge*, and in or before 1801, the *Newcaſtle and Maryport* were alſo propoſed. In 1797, and again in 1802, the *Durham and Cheſter-le-Street* canal was propoſed to join this river near Gateſhead; and in 1803, the *Tyne and Beamiſh* canal was propoſed through part of nearly the ſame tract.

*Tyne and Beamiſh Canal.* In 1803, it was propoſed to make a canal from the *Tyne* river, near Gateſhead, through Gateſhead, Wickham, Lameſley, and Birtly townſhips, to Beamiſh iron works and coal-mines.

ULVERSTONE CANAL. Act 33 Geo. III.—The direction of this ſhort, but large canal, is nearly N.W. for $1\frac{1}{4}$ mile in Lancaſhire; it is level with high-water at ordinary tides, with a ſea-lock at its entrance; its object is to admit ſhips to Ulverſtone town. This canal commences at Hammerſide hill in Morecambe bay in the Iriſh Sea, and terminates at the new baſon and wharfs at Ulverſtone; the canal is 65 feet wide at top, 30 feet at bottom, and 15 feet deep; the lock is 112 feet long; at the loweſt neap tides there is a depth of 9 feet water at the gates, and at ſpring tides of 20 feet; a public ſwing-bridge is built at Hammerſide. That able engineer, Mr. *John Rennie*, was employed on this canal, and completed it about July 1797. This company was authoriſed to raiſe 7,000l, the amount of their ſhares being 50l. each. Coals may be brought to this canal from the *Lancaſter* canal, without paying the ſea duty; ſome iron works have been eſtabliſhed near Ulverſtone ſince the opening of this canal.

*Uppingham Canal.* In 1793, it was propoſed to make a canal from the town of Uppingham in Rutlandſhire, to connect with the *Leiceſterſhire and Northamptonſhire Union* canal, and proviſion is made in its act (33 Geo. III.) for ſuch junctions.

USKE RIVER. The direction of this river is nearly N. for about 4 miles in the county of Monmouth; the tide flows through its whole length; its objects are the export of coals, iron, &c. and the trade of Newport; at Pill-Gwnelly it connects with the *Monmouthſhire* canal, and with the *Sirhowy* tram-road; it commences in the *Severn* river at Naſh, and terminates at Newport bridge.

*Wakefield and Hullet.* In September laſt (1805) notices were given for a rail-way from the *Calder and Hebble* navigation at Bottom boat in Wakefield, to Hullet-hall collieries, with branches to Birſtal and Smithic bridge in the weſt riding of Yorkſhire.

WARWICK AND BIRMINGHAM CANAL. Acts 33 and 36 of Geo. III.—The general direction of this canal is nearly N.W. for 25 miles in the counties of Warwick and Worceſter; it croſſes the grand-ridge without a tunnel; its objects are the ſupply of Warwick with coals, &c. and forming part of the moſt direct water communication between Birmingham and London; at Kingſwood in Rowington, this canal is joined by a branch from the *Stratford* canal. Birmingham is the 6th Britiſh town with 73,670 perſons, and Warwick is the 107th with 5,775 perſons, on the line of this canal; which commences in the *Warwick and Napton* canal in Budbrook pariſh near Warwick, and terminates in the Digbeth cut of the *Birmingham and Fazeley* canal at Digbeth near Birmingham; it has a cut of $\frac{1}{4}$ of a mile to the baſon at Saltesford in Warwick. From the *Warwick and Napton* canal, about ½ a mile, to near Budbrook town, is level; thence 2½ miles to Hatton, is a riſe of about 20 locks; thence to the Stratford branch, about 5 miles, is level; thence to Knowle common, about 4½ miles, is level; thence to Knowle-wharf, 1 mile, is a fall of about 7 locks; thence to near Deritend, about 10 miles, is level; thence to the Digbeth branch of *Birmingham and Fazeley*, 1½ mile, is a riſe of about 5 locks. At the termination at Digbeth a ſtop-lock is erected, which the *Birmingham and Fazeley* company may faſten up, whenever the water in this canal is of leſs depth than 4 feet at ſuch lock. At Haſeley there is a tunnel of 300 yards in length; at Henwood wharf there is an aqueduct over the Blythe river; near Flint Green another over the Cole river; and near its termination at Digbeth another over the Rea river. In May 1796, the northern end of the canal for near 9 miles to Henwood aqueduct was completed and opened; and, on the 19th of December 1799, the whole line was completed and opened. On the 30th of April 1799, a bank of this canal broke, it was ſaid, and the flow of the waters did ſome damage. This company was authoriſed to raiſe 180,000l., the amount of their ſhares is 100l. each. The rates of tonnage will be found in Mr. *John Cary's Inland Navigation*, pages 56 and 57; paving-ſtones, road-materials, and manures for adjoining lands (except lime), are to paſs free on the pounds, or through the locks when the water runs waſte. Huſbandry boats, not exceeding 5 feet wide, may be uſed by occupiers of lands; boats leſs than 70 feet long, or with leſs than 20 tons of lading, are not to paſs the locks without leave. The *Birmingham and Fazeley* company are allowed to take 6d. per ton on all goods which paſs from that canal to this, until they have paid off 3,600l. of their debt, after which they are to take only 5d.; they are alſo allowed 3d. per ton on all goods paſſing from this canal to that.

WARWICK AND NAPTON. Act 34 and 36 Geo. III.—The general direction of this canal, (at firſt called the Warwick and Braunſton,) is nearly Eaſt, for about 15 miles, in the county of Warwick: it is conſiderably elevated, and terminates near to the grand-ridge, on its Weſt ſide: its main object is, the opening of the moſt direct line between Birmingham and London. Warwick is the 107th Britiſh town, with 5,775 perſons; Southam is alſo a conſiderable town near to this canal; which commences in the *Warwick and Birmingham* canal, in Budbrook pariſh near to Warwick, and terminates in the *Oxford* canal at Napton on-the-hill; near Warwick it croſſes the Avon river, on an aqueduct bridge; near Radford and Long-Itchington there are ſmaller aqueducts. This canal is level with the *Warwick and Birmingham* canal at their junction, and is entitled to the waſte water from that canal. This canal was completed on the 19th of December 1799. The company were authoriſed to raiſe 130,000l.; the amount of each ſhare being 100l., but by the laſt act above, the holders of the original 1000 ſhares, were authoriſed to contribute any further ſum, and to be entitled to a proportionate dividend, with original ſhares, on ſuch addition. The tonnage rates are adapted to the principle, of making goods pay a higher rate for ſhort diſtances; ſee *John Cary's* Inland Navigation, pages 59 and 60: paving-ſtones, road-materials, and manures for the adjoining lands, (except lime,) are to paſs free on the pounds and through the locks when the water runs waſte thereat. Boats leſs than 70 feet long, or with leſs than 20 tons of lading, are not to paſs the locks without leave. The *Oxford* canal company are entitled to a variety of rates on goods paſſing out of this canal into that, which ſee in *Cary*, as above.

WAVENEY RIVER. The general direction of this river is nearly S.W. by a bending courſe of about 25 miles, between the counties of Suffolk and Norfolk: it is not greatly elevated in any part; its objects are the import of coals, deals, &c. and export of agricultural products: Yarmouth is the 28th Britiſh town, with a population of 14,845 perſons; Beccles and Bungay are alſo conſiderable towns, on or near this river; which commences in the *Yare* river at Burgh, and terminates at the town of Bungay.

WEAR RIVER. Act 34 Geo. II.—The general direction of this river is nearly S.W. for about 10 miles in the county of Durham; it is not greatly elevated in any part; its principal object is the export of coals. Sunderland is the 34th Britiſh town, with 12,412 inhabitants; Durham is the 74th, with 7,530 perſons; and Biſhops-Wearmouth is the 97th, with 6,126; Monks-Wearmouth and Cheſter-le-ſtreet are alſo conſiderable towns, on or near this river; which commences in the German ocean at Wearmouth near Sunderland, and terminates at Lumley caſtle. There is a rail-way of 7 miles in length from this river to Eaton-Main colliery, and a great number of others of conſiderable lengths, for conveying coals to the ſtaiths and ſpouts where barges and ſhips are loaded with them. Eighteen different ſorts of coals, or rather the produce of ſo many different pits, are uſually ſhipped from this river for the London market, amounting in the whole to 195,000 chaldrons annually; ſee *Edington's Eſſay on the Coal-trade*, page 31. In 1761, Mr. *John Smeaton* was conſulted, about the building of the firſt lock on this river near Harraton; the ſinking of its foundations being thought to endanger the coal-mines which were working *under* the river at that place, the river was then to be deepened and made navigable, from Briddick-ford to the new bridge, the eſtimate being 3700l. In the year 1802, a new dry or graving-dock was hewn out of the rock on the North ſide of the river in Monk-Wearmouth. On the 9th of Auguſt 1796, a grand iron bridge of one arch, 236 feet ſpan, and 100 feet high above high-water mark, was completed over this river at Wearmouth near Sunderland, as we have already mentioned in this article, and in our article BRIDGE. The importance of this bridge, beſides its advantage in admitting ſhips further up the river, will appear from the tolls for paſſing over it, having been let for the current year at 2080l. At the mouth of this river there are two piers for the improvement of Sunderland harbour; in 1802, a new light-houſe, 70 feet high, was built on the North pier, furniſhed with reflecting lamps: during tide-time every night, another light is exhibited below the principal one, as a notice to ſhips of the proper time to enter the harbour. In 1797, and again in 1802, the *Durham and Cheſter-le-ſtreet* canal was propoſed to join this river near Cheſter, and thence extend the navigation to Durham.

WEAVER RIVER. Acts 7 Geo. I. and 34 Geo. II.—The general direction of this river is nearly S.E. by a crooked courſe of 20 miles in Cheſhire: it is but little elevated in any part; its objects are the import of coals and Cumberland red iron-ore, and the export of ſalt and agricultural products: Frodſham, Northwich, and Middlewich, are conſiderable towns near this river; which commences in the *Merſey and Irwell* navigation, near Weſton, and terminates at Winsford bridge: the riſe is about 45¾ feet by 10 locks: the boats are from 50 to 100 tons burthen: the truſtees for this navigation were authoriſed to borrow money at 5 per cent. intereſt, and 1 per cent. for the riſk; in 1759, the debt amounted to 20,200l., borrowed at 5 and 4½ per cent.: this debt has long ago been paid off; and, there being no private intereſt in the concern, to the amount of 3000l. has been paid in ſome years, to the county treaſurer of Cheſhire, to be laid out in amending and repairing the public bridges, and in the repair of high-ways leading to the ſalt-works, agreeable to the directions of the firſt act. The ſalt-mines at Northwich are 300 feet deep. In 1804, it was in contemplation to make a ſide-cut to this river, from near Frodſham, into the *Merſey* at Weſton or Weſtern point, for avoiding the bar or ſhoal at the mouth of this river.

Welland River. Act 34 Geo. III.—The general direction of this river is nearly S.W. for about 37 miles in the county of Lincoln, and ſkirting the county of Northampton; it is not much elevated above the ſea in any part; its objects are the import of coals, deals, &c. the export of Ketton free-ſtone, Collyweſton white ſlates, agricultural products, &c.; near Crowland it connects with Catwater, a branch of the *Nen* river. Boſton is the 102d Britiſh town, with 5,926 inhabitants; Spalding, Crowland, Market-Deeping, and Stamford, are alſo towns of ſome note on this river; which anciently was navigable for conſiderable veſſels, from Foſſdike-waſh to Spalding; but owing to the conſtant changes, which have been taking place in theſe ſurpriſing fens, and their outfall into the waſh, we learn, that in 1618, there was not 6 inches' depth of water at low tide in the channel, 2 miles below Spalding; ſo that when the commiſſioners of ſewers inſpected the ſame, their boat was obliged to be carried in a cart upon the ſands for 3 or 4 miles below that town. In 1721, Mr. *Nathaniel Kinderly* (ſee his Ancient and Preſent State, &c. page 83) recommended the cutting of a new channel, from near the mouth of Glen river to Wyberton near Boſton, by which the outfall of this river would be into the channel of the *Witham* river, inſtead of Foſſdike waſh. The ſubſequent contractions of the *Welland* river, by embankments near its mouth, ſomewhat improved the navigation to Spalding, and delayed until the year 1794 the adoption of Mr. Kinderly's propoſed cut: in future the commencement of this navigation is to be in the tide-way of the *Witham* river at Wyberton roads, and it terminates at Stamford bridge. The new cut is to commence near the Ship alehouſe in Wyberton, where there is to be a ſea-ſluice againſt the *Witham*, for the river and flood waters, with gates pointing to ſea and to landwards; the threſhold of this ſluice is to be one foot below low water mark, and it is to be 50 feet wide in the clear; adjoining to the ſluice is to be a tide-lock, for the uſe of the navigation, 60 feet long, and 8 feet wide, in the clear. From this ſea-ſluice, the cut is to be continued weſtward, with a regular aſcent in its bottom, to 4 feet below the ſill of Vernat's ſluice, and is to terminate in the old *Welland* river, near Hooton's Gibbet: the width of the bottom of this new cut is to be 50 feet, and the ſides are to batter 2 feet for 1 in height; at the diſtance of 50 feet from the edge of this cut on the South ſide, and 30 on the North ſide, banks 11 feet in height are to be made, to retain the floods and prevent their overflowing the adjoining fens, a precaution which has been adopted through the whole courſe of the fens. Meſſrs. *John Hudſon*, *George Maxwell*, and *Edward Hare*, are appointed commiſſioners for ſetting out, and employing proper perſons to execute the new cut, ſluices, locks, &c. and are to cleanſe the channel of the *Welland* for ſome diſtance above the new cut, and erect a ſufficient dam acroſs the river below the entrance of the ſame, at Shepherd's hole, to ſtop the tide waters and turn the land waters through the new cut; the rates of tonnage for navigating of which, will be found in *Phillips*'s 4to. *Hiſtory*, *App.* page 179. A bridge is to be built over the new cut at Foſſdyke Inn: at Crowland, there is a moſt ancient and curious bridge on this river, ſpringing from three different abutments, and meeting in the middle. See our article Bridge. In 1797, it was ſtated that 10,000l. had been ſubſcribed for carrying the above new cut and improvements into effect; and we hope that ere long the ſame will be completed. Truſtees are appointed in the above act, for receiving the tolls and maintaining the works when completed by the commiſſioners. The greater part of the courſe of this navigation from Spalding to near Peakirk upwards, and from Market-Deeping to Stamford, is by modern cuts, on the north-weſt ſide of the old river, for avoiding its imperfect channel.

*Welſhpool and Leominſter.* About the year 1794, a canal was propoſed from the *Montgomery* canal and *Severn* river near Welſhpool, to the *Leominſter* canal at Woſerton; paſſing Biſhops-Caſtle and Ludlow in its courſe.

Wey River. The general direction of this river, is nearly S.S.W. for 20½ miles in the county of Surrey: it is not greatly elevated; its objects are the import of coals, deals, &c. and the export of chalk and agricultural products; at Weſtley near Weybridge, it is joined by the *Baſingſtoke* canal. Godalmin, Guilford, and Chertſey, are conſiderable towns on or near to this navigation; which commences in the *Thames* river at Ham-Haw near Weybridge, and terminates at the town of Godalmin. From the *Thames* to Guilford bridge, 15¼ miles, is a riſe of 86½ feet; in this part the channel of the river was very early improved by ſide-cuts, and pound-locks, (ſaid to be among the firſt erected in England, and to have been introduced by Sir *Richard Weſton*); from Guilford bridge to Godalmin, is a canal 5½ miles, with a riſe of 32½ feet; which is ſupplied by a feeder from the Wey at Godalmin. In 1791, and again in 1803, this navigation was propoſed to be joined near Godalmin by a canal from the *Itching* river, (ſee *Portſmouth and Croydon*). In 1800, the *Grand Surrey* was propoſed to be extended to this river near Weſtley; and in 1802, a branch from the *Grand Junction* canal was intended to connect with this river by means of the *Thames* at Ham-Haw.

Wharfe River. The general direction of this river is nearly N.W. for about 9 miles, between Ainſty Liberty and the Weſt Riding of Yorkſhire: it is not much elevated above the level of the ſea: its objects are the carriage of coals, free-ſtone, &c. and the export of agricultural productions. Tadcaſter and Cawood are conſiderable towns on or near to this river, which commences in the *Ouſe* river near Cawood, and terminates at the town of Tadcaſter.

Whitehaven Brook. This brook is navigable but a very ſhort diſtance, in a S.E. direction at its mouth, which is wide, conſtituting the harbour of Whitehaven in Cumberland: its chief object is the export of coals, lime, and free-ſtone. This harbour, ſituate on the Iriſh ſea, has had ſeveral acts paſſed for its improvement, viz. 7 and 10 Anne, 13 Geo. II., 1, 2, 28, 32, and 45 Geo. III. and in September laſt (1805) notices were given for a further application to parliament. Whitehaven is the 62d Britiſh town with 8,742 inhabitants. Mr. *John Smeaton* was conſulted in 1768, on the building of a north pier, and extending the ſouthern one within 200 feet of it. In 1796, a violent ſtorm happened, which conſiderably damaged the quays of this harbour. There are ſeveral rail-ways from this harbour, to the famous coal-mines in its vicinity. On the 4th of Auguſt 1738, the firſt rail or waggon-way was opened at this place, leading to Harrithwaite and Woodhouſe collieries. In 1802, the Henſingham lime-works were opened. On the 9th of Auguſt, 1803, the rail-way, 700 yards in length, paſſing over Branſty-arch, or Road-bridge, to Howgil and Whingill coal mines, were opened: and in the ſame year theſe to Brackenthwaite mine were opened. On 23d March laſt (1805) the William Pit, at 750 yards diſtance from the north wall of the harbour, was opened. Some of the veins of coals in theſe pits are 7½ to 12 feet thick, and from the whole of them 900 tons or upwards of coals are raiſed daily: one of theſe mines extends ⅔ of a mile under the ſea, at about 600 feet beneath its bottom; inclined planes, 200 fathoms long, being uſed, for drawing up boxes of coals and others of water, from the extremities of theſe workings under the Sea, to the bottoms of the ſhafts; theſe boxes are drawn up the planes by horſe gins; for which purpoſe, and dragging the coal-waggons to the ſhafts, 100 horſes are conſtantly employed under ground in theſe pits. The fire-damp often proves fatal to the men and horſes employed in theſe works. There is a fine white free-ſtone quarry on the weſt ſide of the harbour.

*Wibſey and Dewſbury.* In 1802, a rail-way was propoſed from the *Calder and Hebble* navigation at Ravensbridge in Dewſbury, to Low-moor iron-works in Wibſey, about 7 miles in length.

*Wilden and King's-Bromley.* In 1760, the line for a canal was ſurveyed by Mr. *James Brindley* and Mr. *John Smeaton*, from the *Trent* river at Wilden-ferry to King's-Bromley near Litchfield, 25 miles, with a riſe of 110 feet by 19 locks, with a branch therefrom to Longridge near Burſlem, 30¼ miles, with 166¾ feet riſe, by 28 locks; from which laſt a level branch was again propoſed of 3½ miles, to Newcaſtle-under-line: another branch of 2½ miles, to Litchfield mill-pool, 18 feet riſe, and 3 locks, and thence ½ a mile farther with 30 feet riſe, and 5 locks: another level branch was propoſed of 10 miles, to Fazeley near Tamworth, and thence ½ a mile, to the Tame river, 17 feet riſe, by 3 locks. This canal was intended to be 24 feet wide, and 2½ deep, with fords inſtead of bridges: the eſtimate was 100,200l. Mr. *Smeaton* ſuggeſted an extenſion of this canal, over Harecaſtle-hill, by deep-cutting, with reſervoirs and ſteam-engines, for ſupplying the ſummit. The *Trent and Merſey*, *Newcaſtle-under-line*, and *Coventry* canals have ſince accompliſhed what this ſcheme had in view.

WILTS AND BERKS CANAL. Acts 35 and 41 Geo. III.—The general direction of this canal is nearly N.E. by a bending courſe of about 52 miles, in the counties of Wilts and Berks: it croſſes the grand ridge at the foot of the chalk-hills without any tunnel: its objects are the import of coals from both its extremities, the export of farming products, &c. Abingdon, Wantage, Swindon, Wotton-Baſſet, Chippenham, Calne, Meikſham, and Trowbridge, are conſiderable towns on or near to this canal, which commences in the *Kennet and Avon* canal at Semington, and terminates in the *Thames and Iſis* navigation at Abingdon. It has a cut of about 1½ mile to Chippenham, one of about 3 miles to Calne, and another of about 1 mile to Wantage: the ſummit-level extends from near Wotten-Baſſet, to near the extremity of Wilts. The locks are calculated for long, narrow boats. On the Calne branch there is a ſhort tunnel, under the road at Cuningham park; and a principal aqueduct-bridge over Broadtown brook near Wotton-Baſſet. The riſe of the road over the canal bridges is nowhere to exceed 3 inches in a yard; the ſprings and ſtreams within 2000 yards may be taken; the uſe of inclined-planes inſtead of locks is provided for in the act; but they will not be neceſſary, the canal being generally cut through clayey ſoils that have plenty of water: half-mile ſtones are to be erected on the canal banks. The company have been authoriſed to raiſe 311,900l. the amount of ſhares being 100l. each. The inhabitants of Calne made an offer, in Auguſt 1799, we are told, to cut the branch to that town, on being allowed the tolls thereon for ſo doing. In Auguſt 1799, the weſtern end of the line was completed and filled, and on the 1ſt May 1801, by the completion of the *Kennet and Avon* to Semington, the junction was formed, and 22 miles of the line to the aqueduct near Wotten-Baſſet, with the Calne and Chippenham branches, have ſince been uſed, principally in bringing in Somerſetſhire coals. In September 1800, two branches of the *Thames and Severn* canal, by Faringdon and Highworth, were propoſed, to join this canal at Uffington and Shrivenham. In 1803, the Ayleſbury branch of the *Grand Junction* canal was propoſed to connect with this canal by means of the *Iſis* river at Abingdon.

*Winſton and Stockton.* In 1768, Mr. *James Brindley* and Mr. *Robert Whitworth* ſurveyed the line for a canal from the *Tees* river at Stockton in *Durham* county; paſſing Hartburn, Cothams-ſtob, Moor-houſe, Oak-tree, Maidendale, Bank-top, Darlington, Cockerton, Lower-Walworth, Legg's-croſs, Killerby, and Staindrop, to Winſton: with a branch 1¼ mile from Lower-Walworth to the Tees at Pierſebridge; another from Darlington, 3 miles to Croft-bridge on the Tees; and another from Cothams-ſtob, 2 miles to the Tees at Yarm. The riſe from Stockton to Winſton is 328 feet. A feeder was to be taken from the Tees river, 3 miles above Winſton. The export of coals, lime, and lead, was the object of this propoſed canal.

WISBEACH CANAL. Act 34 Geo. III.—The direction of this canal is nearly S.E. for 6 miles, in the counties of Cambridge and Norfolk; it is but very little higher than the ſea, being embanked through the level fens: its object is a communication between Wiſbeach and Lynn, inſtead of an old part of the *Nen* river near it, which is almoſt grown up. Wiſbeach is the only conſiderable town near this canal, which commences in the *Nen* river at the old ſluice in Wiſbeach, and terminates in the *Nen* river again at Outwell (at the commencement of Well-creek, a branch of that river leading to the great *Ouſe* river): it is ſtraight and level, having flood locks at its extremities. This company were authoriſed to raiſe 20,000l. the amount of each ſhare being 105l. All goods entering or paſſing out of this canal are to pay 3d. per ton, except government ſtores and baggage, road-materials, manures, and materials for the uſe of the Fen-Corporation: huſbandry boats may alſo be uſed toll free, but not paſs the locks. The commiſſioners for the *Nen* navigation are to have 100l. out of theſe tolls, and the remainder, after paying intereſt on the debt, is to be applied in the repair and improvement of Well-creek.

WITHAM (*old*) RIVER. Act Geo. II.—The general direction of this river is nearly N.W. for about 41 miles in the county of Lincoln; it is but little elevated above the ſea in any part: its objects are the import of coals, deals, &c., the export of farming products, and forming part of the inland communication between Lynn and Hull, Liverpool, Mancheſter, &c. Near Tatterſhall it is joined by the *Horncaſtle* navigation; at Chapel-hill by the *Sleaford* navigation; and at Wyberton roads the new outfall and navigation of the *Welland* river are to join this river. Lincoln is the 76th Britiſh town, with a population of 7,398 perſons, and Boſton is the 102d, with 5,926 perſons; Tatterſhall is alſo a conſiderable town near this river; which commences at the Scap or Scalp in the tide-way of Boſton deeps in the Waſh, and terminates in the *Foſſdyke* canal, or new navigation at Brayford Meer. This river below Boſton, about 4 miles, was anciently ſo deep, and was ſo much frequented by ſhips, that in the 6th year of king John, when the merchants of London paid only 836l. as a tax on their lands and goods, Boſton contributed 780l. A gradual decay and ſilting up of the channel and harbour took place to ſuch a degree, that when in 1761 Meſſrs. *John Grundy*, *Langley Edwards*, and *John Smeaton* examined the ſtate of this navigation, and of the drainage of the adjoining fens, through which this river is embanked on both ſides through nearly its whole length, owing to the long neglect of the banks, which ſhould have confined the returning tide and the land-waters, ſo as to ſcower the channel, they reported that 30 ton barges could then ſcarcely reach Boſton, while the navigation above that town was entirely loſt, and the ancient channel was in ſeveral places entirely grown up and abandoned by the water, in its ordinary ſtate. Mr. *Smeaton* then recommended the erection of a ſea-ſluice upon this river below Boſton, the ſill thereof as low as low-water, with 3 openings, amounting to 50 feet wide; theſe to be furniſhed with doors pointing to ſea-ward, and draw-gates behind them gauged, or having their tops, two feet below the ſurface of the ſens, for always retaining a proper quantity of water in the river in dry ſeaſons; alſo a ſea-lock at the ſame place for the navigation, furniſhed with three pair of gates, two of them pointing to the land and one to the ſea: the ſtraightening, enlarging, and deepening of the river above Boſton to 80 feet at top, 50 at bottom, and 10 feet deep, were recommended, and the erection of three pound-locks, furniſhed with flood-gates or opening-weirs adjoining, below Lincoln, and one other ſuch lock above. The eſtimate for ſuch of theſe works as related to draining, was 38,000l., and for the navigation works 7,370l. It was remarked that Lincoln high-bridge had but 15½ feet clear width of water-way, above which a hard gravelly place, probably an ancient ford, called Brayford head, covered frequently with only 3 feet of water, acted as a weir for holding up the waters of Brayford meer and the *Foſſdyke* canal. When Mr. *Smeaton* was afterwards conſulted in the year 1782, he objected to a navigation lock which had been in the interim erected below Lincoln town, and recommended the cutting off the communication between *Foſſdyke* canal and Brayford meer, by a pound-lock with gates pointing to the canal, and to deepen this river through and above Lincoln bridge, and to remove Brayford head, ſo as to lower the water in Brayford Meer: the principal wharfs appear to have been ſince made, and the trade of Lincoln is now carried on upon this meer or water. By the acts of 32 Geo. III. for *Horncaſtle* and *Sleaford* navigation, thoſe companies were required to contribute equally with this company in the expences of deepening and improving this river through Lincoln high-bridge, and thence to the *Foſſdyke* canal, in the next 7 years; in conſequence of which, goods paſſing on this river to or from the *Horncaſtle* or *Sleaford* navigations, are to pay only half the accuſtomed rates on this river. In 1803 it was in contemplation to further improve the navigation of this river below Lincoln. Much has been written on a prohibition ſaid to exiſt againſt the ſhipping of coals from this river, on account of its preventing a rivalry with Newcaſtle and Sunderland coals in the London market, by the produce of the Yorkſhire, Derby, and Nottingham mines being brought by the *Trent*, the *Foſſdyke*, and this navigation, to Boſton deeps; an expectation not much better founded, we fear, than that the opening of the *Stover* canal would have any effect on the London coal-market.

WORCESTER AND BIRMINGHAM CANAL. Acts 31, 38, and 44 of Geo. III.—The general direction of this canal is nearly N.E. for 29 miles in the counties of Worceſter and Warwick; it croſſes the grand-ridge by a tunnel: its objects are the export of coals, and a more direct communication between Birmingham and the *Severn* river: at Selly Oak it is joined by the *Dudley* canal, and at Kings Norton by the *Stratford* canal. Birmingham is the 6th Britiſh town, with a population of 73,670 perſons; Worceſter is the 40th, with 11,325 perſons; Bromſgrove and Droitwitch are alſo conſiderable towns near this canal; which commences in the *Severn* river at Diglis juſt below Worceſter, and terminates in the old *Birmingham*, and the *Birmingham and Fazeley* canals, at their junction at Farmers bridge at the upper end of the town of Birmingham. From the *Severn* to Tardebig, 15 miles, is a riſe of 428 feet by 71 locks; thence to the *Birmingham* canal, 14 miles, is level. The width of the canal at top is 42 feet, and the depth is 6 feet; the locks are 80 feet long and 15 feet wide; the boats are of 80 tons burthen. At Worceſter there is a very fine baſon for the canal boats. There are 4 or 5 principal, and ſeveral ſmaller culverts: the principal tunnel at Weſt Heath is 2700 yards long, 18 feet high, and 18½ feet wide within the arch, the depth of water therein is 7½ feet; at Tardebig is another of 500 yards in length; at Shortwood is another of 400 yards in length; at Oddingley one of 120 yards; and, at Edgbaſton another of 110 yards in length: four of theſe tunnels are upon the ſummit-pound. Near Coſton-Hacket there is an immenſe piece of deep cutting; in 1794, Mr. *Carne*'s machine worked by a horſe at length, was uſed for excavating the ſoil, inſtead of wheeling it out in barrows. Where the ſummit-pound of this canal connects with the *Birmingham*, the *Dudley*, and the *Stratford* canals; ſtop-locks are erected, which the ſeveral companies may ſhut and lock up, when the ſupplies of this or the other canals fail, ſo as to endanger the lowering of the ſummit-pound, to obſtruct the navigation. Mr. *John Smeaton* was one of the engineers to this canal, the ſcheme of which was laid, and a bill was brought into parliament in 1790, but the oppoſition of intereſts, and natural difficulties of this vaſt undertaking then proved fatal to it; the great anxiety and fatigue which Mr. *Smeaton* underwent in this arduous undertaking, are thought to have injured his health and to have ſhortened the days of that very able and excellent man. In May 1796, the eaſtern end of this canal, as far as the *Stratford* canal at Kings-Norton, was completed. The arching of the Weſt-heath tunnel was begun on the 28th of July 1794, the whole of it was turned by the 25th of February 1797, (1780 yards of it having been completed in the year 1796) and in March 1797, the navigation was extended through it to Hopwood wharf, and in the following year, the ſame was extended to the weſtern end of the ſummit-pound at Tardebig. The company were authoriſed by their two firſt acts to raiſe 399,929l. 1s. 1½d.: their whole ſhares being made hereby, of the odd value of 138l. 17s. 9d. each: theſe were ſaid to be depreciated in value almoſt to nothing; but in 1802, they had riſen to 40l. each. The laſt act was for raiſing a further ſum of money for completing the very difficult part of the line, and ſupplying lockage-water, by ſteam-engines to pump it up from the *Severn*, by reſervoirs, &c. which yet remains to be accompliſhed. The rates of tonnage owing to the ſeveral junctions with neighbouring canals are very complicated; ſee *Cary's Inland Navigation*, pages 68 to 70. Two-pence per ton is charged on goods entering the Worceſter baſon from the *Severn* river, to be there unloaded. This company guarantees the future profits of the *Droitwich* company to the extent of 5 per cent. annually on each ſhare, and thoſe of the *Stourbridge* company to 9l. per cent. on each ſhare: they are alſo to compenſate the water-bailiff of Worceſter for his dues on coals ſold on the *Severn* at Worceſter; they are alſo to pay to George Perrot eſq. as owner of the Stratford *Avon* navigation, 400l. per annum for loſs of his tolls on the upper part of that river by the making of this and the *Stratford* canal, beſides making up any deficiency there may hereafter be, in his rents of 1227l. for the tolls on the lower part of that river. About the year 1793, a branch was propoſed, it appears, from this canal near Hanbury-Hall to the *Droitwich* canal at that town.

WYE RIVER. The general direction of this rapid and romantic river is nearly N.W. by a very bending and crooked courſe of about 85 miles, in the counties of Monmouth and Hereford, and Brecknock, in South Wales, and ſkirting the county of Glouceſter: its northern end is conſiderably elevated: its objects are the carriage of coals, and the export of agricultural products; at Hereford it is approached very near, if not joined, by the *Hereford and Glouceſter* canal. Hereford is the 89th Britiſh town, with a population of 6,828 perſons: Chepſtow, Colford, Monmouth, Roſs, and Hay are alſo conſiderable towns on or near to this river; which commences in the *Severn* river at Beachley, and terminates at the town of Hay. The tide often riſes in the mouth of this river, to the extraordinary height of 40 feet; Chepſtow bridge over the ſame, is of great height above the water at low tide. In 1802, and again in 1804, it was in contemplation to make a horſe towing-path by the ſide of this river, and by deepening the ſhallows in ſeveral places to improve its navigation. In 1802, the *Dean-Foreſt* railway was propoſed to join this river at Engliſh-Bichnor, we believe; in the ſame year notices were given, for an intended rail-way from this river at Hereford, to join the ſame again oppoſite to Lydbrook; and in March laſt (1805) another railway was propoſed from this river to the *Monmouthſhire* canal.

WYRLEY AND ESSINGTON CANAL. Acts 32 and 34 Geo. III.—The general direction of this canal is nearly S.W. by a very crooked courſe of 23 miles in the county of Stafford: it is conſiderably elevated, and terminates at its weſtern end near, or upon the grand-ridge: its object is the export of coals, iron, and lime, which abound in its courſe: Wolverhampton is the 33d Britiſh town, with a population of 12,565 perſons; Litchfield and Walſall are alſo conſiderable towns on or near to this canal; which commences in the detached part of the *Coventry* canal at Huddlesford (near to Whittington brook, and the commencement of the *Birmingham and Fazeley* canal) and terminates in the old *Birmingham* canal near Wolverhampton: there is a branch of $5\frac{1}{2}$ miles to Hay-head lime-works; another of $2\frac{1}{2}$ miles to Lord's-Hay coal-pits; another of near 4 miles at Wyrley-bank collieries, with a branch from this laſt near 1 mile to Eſſington new collieries; there is alſo a branch $\frac{1}{2}$ a mile to near Walſall town, which terminates within $\frac{1}{2}$ a mile of the branch of the old *Birmingham* thereto. From the *Coventry* canal to near Cannock-Heath reſervoir, $7\frac{1}{2}$ miles, is a riſe of about 264 feet, by 30 locks; thence to the old *Birmingham* canal, $15\frac{1}{2}$ miles, is level; the Lords-Hay, Hay-head, and Walſall branches are all level with the long pound: the Wyrley branch riſes about 36 feet, by 6 locks, in the firſt $\frac{1}{2}$ mile, the remainder thereof is level, and therefrom the Eſſington branch riſes about 24 feet, by 4 locks. This canal is 28 feet wide at top, 16 at bottom, and $4\frac{1}{2}$ feet deep. No water is to be taken from the old *Birmingham* canal, but a lock is erected at the junction, and this canal is to be conſtantly kept 6 inches higher than that, or all boats are to be ſtopped, by a man ſtationed there for that purpoſe: the ſurplus water from this is to be vented into the old *Birmingham* canal. Litchfield water-works pipes were to be carefully guarded in cutting this canal. Branches of 5 miles in length may be made to this canal by the owners of the mines, if they waſte no water. Mr. *William Pitt* was the engineer: and the canal and works were long ago completed. The company were authoriſed to raiſe 160,000l. the firſt 35,000l. in 125l. ſhares; on the extenſion of the canal in 1794, the company were required to purchaſe the ſhares of certain diſcontented proprietors: the new ſhares are 100l. each. The rates of tonnage will be found in Mr. *John Cary's Inland Navigation*, p. 47 and 48. Leſs than 20 tons in a boat is not to paſs the locks without paying for that lading, except empty boats on their return. In 1792, it was propoſed to make a branch to Stow-heath, and two others into Aſhmore-park.

YARE RIVER. The direction of this river is nearly W. by a bending courſe of about 22 miles, in the county of Norfolk: it is not much elevated in any part; its objects are the import of coals, deals, &c. and the export of agricultural products: at Yarmouth this river is joined by the *Thyrn* river, and at Burgh by *Waveney* river. Norwich is the 11th Britiſh town, with a population of 36,854 perſons, and Yarmouth is the 28th, with 14,845 perſons; there are no other conſiderable towns near this river; which commences in the German Ocean at Gorleſton-fort, and terminates at the water-works and mill in Norwich: at Yarmouth there is a draw-bridge for admitting maſted veſſels above it. The quay of this port is $1\frac{1}{3}$ mile in length, and in ſome parts 150 yards in breadth: a curious kind of low carriages called Yarmouth-Carts are uſed for conveying the goods from the quay to the warehouſes. In 1804, St. Michael's Coſlany bridge over this river in Norwich city was taken down, and a caſt-iron bridge erected by Mr. *Froſt* in its ſtead. In 1785, and again in 1802, the *London Lynn and Norwich*, or North London canal, was propoſed to join this river at Norwich.

YORE RIVER. Act 7 Geo. III.—This river, ſometimes called the Ure river, has nearly a N.W. direction for about $8\frac{1}{2}$ miles in the Weſt, and ſkirting the North Riding of Yorkſhire: its objects are the ſupply of Borough-bridge and Ripon, and the export of agricultural products: at Myton it is joined by the *Swale* river. This navigation commences in the *Ouſe* river at Linton, and terminates in the *Ripon* canal at Milby. From the *Ouſe* to the *Ripon* canal, is a riſe of 11 feet; at Linton river is a lock, and a dam or weir ſo made up as to allow about 1 inch per mile in this diſtance, for a ſtream navigation. Mr. *John Smith* was the engineer, who in 1767 referred to Mr. *John Smeaton* for his opinion on the height of Linton dam, and other matters relating to the works then going on.

For further illuſtrating this part of our ſubject, we intend to give a map of the Britiſh iſlands, ſufficiently large to diſtinguiſh all the navigable rivers, canals, rail-ways, harbours, &c.; and having adopted a method, by which the inconveniences of large folding-maps will be avoided, and yet perfect facility be given, of reference from any page of the map to the other, this will probably be the firſt of a ſeries of maps, for deſcribing more particularly than has yet been done, ſeveral uſeful and curious particulars relating to the topography and preſent ſtate of our own country.

CANAL, *Canalis*, in *Anatomy*, is a term applied to ſeveral tubular cavities in the bones, and the ſoft parts of the body.

CANAL *of the lower jaw*, a conſiderable excavation under the ſockets of the teeth, in which the nutrient veſſels and nerve of the teeth are lodged. See SKELETON.

CANAL *of Fontana*, a ſmall channel in the ligamentum ciliare, between the ſclerotic and choroid coats of the eye. See EYE, *Anatomy of*.

CANAL *of Petit*, *Canalis Petitianus*, is formed in the anterior part of the membrana hyaloidea, round the margin of the cryſtalline lens. See EYE, *Anatomy of*.

CANAL *of the vertebræ*, a large tube, containing the medulla ſpinalis, formed in the poſterior part of the vertebræ; and extending from the occiput to the ſacrum. See SKELETON.

CANAL, in *Architecture*, is applied to the furrows on the face of, or underneath a larmier, ſometimes alſo called porticos; and fitted up with reeds or flowers; ſometimes to thoſe cavities, ſtraight or winding, made on the caulicoles of a capital. See SOFFITA.

CANALS are alſo uſed for the flutings of a column or pilaſter.

CANAL *of the volute*, in the Ionic capital, is the face of the circumvolutions, incloſed by a liſtel.

CANALE, in *Geography*, the chief town of a canton of the ſame name in the department of Gole, or iſland of Corſica, and diſtrict of Baſtia, containing 1087 inhabitants.

CANALES, in *Ancient Geography*, a place of Italy, in that part of Magna Græcia called Meſſapia, 30 miles from Lapatia, near the gulf of Tarentum. Anton. Itin.

CANALICIUM *aurum*, or CANALIENSE, that gold which is dug out of mines, or veins under ground.

CANALICULATA, in *Conchology*, a ſpecies of BULLA, deſcribed by Linnæus, the ſhell of which is cylindrical, and the whorls of the ſpire grooved. Obſ. This is browniſh or teſtaceous, clouded with a paler colour. Native place unknown.

CANALICULATA, in *Entomology*, an African ſpecies of BUPRESTIS, of a duſky colour, with entire wing-caſes; abdomen grooved beneath; tail armed with four teeth. Fabricius.

CANALICULATE *leaf* and *ſtalk*, in *Botany*. See LEAF and STALK.

CANALICULATUM, in *Conchology*, a ſpecies of BUCCINUM, the ſhell of which is ſpotted, and the whorls of the ſpire canaliculated. Argenville, &c. The ſpire conſiſts of 17 whorls. Its native place is unknown.

CANALICULATUS, a ſpecies of TURBO found in India. This ſhell is ſulcated, and tranſverſely ſtriated; colour white, varied with green, and ſometimes cheſnut; whorls of the ſpire ſix, and very convex. Chemnitz, &c.

CANALICULATUS, in *Entomology*, a ſpecies of CERAMBYX (*Prionus*) found in the Weſt Indies, but rarely. The thorax is crenated at the margin; dorſal groove villoſe and white; antennæ ſhort. Fabr. This intereſting ſpecies is deſcribed by Fabricius from a ſpecimen in the muſeum of Dr. Hunter; another occurs in the cabinet of Mr. Donovan.

CANALICUM, in *Ancient Geography*, a place of Italy in the Aurelian Way, in the paſſage from Rome to Arelatum by the Maritime Alps, 12 miles from Vada Sabbatia; (Anton. Itin.) it is alſo called *Canalium*, and is marked in the map of M. d'Anville in Liguria, towards the N.W. of Savo.

CANALIS, in *Entomology*, a ſpecies of BRUCHUS, of a ſmall ſize, that inhabits India. The colour is ſomewhat ferruginous; wing-caſes black at the tip; tail black; central line white. Fabricius.

CANALIS is uſed by *Surgeons* for an oblong, concave inſtrument, in which to put a broken limb, leg, or thigh. It is made either of braſs, wood, or earthen ware, ſometimes even of ſtraw fitted with linen cloth.

CANALIS *arterioſus*, in *Anatomy*, the veſſel which joins the trunks of the pulmonary artery and the aorta in the fœtus. See FŒTUS.

CANALIS *carotideus*, a canal in the petrous portion of the temporal bone, through which the internal carotid artery enters the cavity of the cranium, and a ſmall nerve paſſes from the ſixth pair to the ſuperior cervical ganglion of the great ſympathetic nerve. For the deſcription of this canal, ſee SKELETON.

CANALIS *medius*, the canal of communication between the third and fourth ventricles of the brain. See BRAIN, *deſcription of*.

CANALIS *naſalis*, the tube which conveys the tears from the lacrymal bag into the noſe. See EYE, *Anatomy of*.

CANALIS *uteri*. See VAGINA.

CANALIS *venoſus*, a branch of the umbilical vein, which terminates in one of the hepatic veins in the fœtus. See FŒTUS.

CANALIS *Trajanus*, and CANALIS *Ptolemæus*. See CANAL, *ſupra*.

CANALS, *ſemicircular*, of the petrous portion of the temporal bone. See EAR.

CANALUVII MONTES, in *Ancient Geography*, mountains of Macedonia, ſo called by Ptolemy, and ſuppoſed to be the ſame with the *Candavii* of Livy, and the *Candavii montes* of Pliny and Strabo; ſituate in the country called *Candavia*.

CANANDAQUA, in *Geography*, a poſt town, lake, and creek of America, in Ontario county and ſtate of New York. It is the ſhire town of the county, ſeated on the north end of the lake of the ſame name, at its outlet into Canadaqua creek. The lake is about 20 miles long and , broad, and conveys its waters in a N.E. and E. courſe, 35 miles, to Seneca river. This is the ſeite of an ancient Indian town of the ſame name, and ſtands on the road from Albany to Niagara, 16 miles W. of Geneva, and 235 miles N.W. from the city of New York. It is now in a flouriſhing ſtate. By the ſtate cenſus of 1796, there appeared to have been 291 electors in this townſhip.

CANANEA, a ſmall oblong iſland of Brazil in South America, belonging to the Portugueſe, oppoſite to the mouth of Ararapiza river; on the ſouth of which ſtands the town of Cananea, guarding the entrance of the bay. The iſland lies about 37 leagues from St. Vincent. S. lat. 25° 10′. W. long. 47° 12′.

CANANGA, in *Botany*, Juſſieu p. 284. Aubl. Guian. tab. 244. Claſs and order, *polyandria polygynia*. Nat. Ord. *Anonæ*, Juſſ. Eſſ. Ch. Petals ſmall, germs numerous, capſules or berries egg-ſhaped, peduncled, one-ſeeded. Juſſieu obſerves, that the plant for which Aublet formed this genus, is probably a congener of Sonnerat's uvaria longifolia; Ind. 2. p. 233. tab. 131. and alſo of Aublet's own genus Aberemoa, whoſe large berries have ſhort partial peduncles. La Marck has united Aublet's Cananga to the Linnæan genus uvaria, which he calls in French Cananga, (ſee UVARIA *Monoſperma*) and has of courſe alſo admitted Sonnerat's uvaria longifolia. Aublet's Aberemoa, which was accidentally omitted in its proper place in this work, is conſidered by La Marck as a diſtinct genus nearly allied to uvaria, but not yet fully deſcribed, having been ſeen by Aublet only in fruit. The fruit of Aberemoa is ſaid by Aublet to conſiſt of a roundiſh head of dry, egg-ſhaped, one-celled, one-ſeeded berries, ſupported by a common peduncle two or three inches long. It is produced by a tree which is a native of Guiana, the bark of which is blackiſh; the wood white and hard; and the leaves alternate, ſimple, about a foot and half long, and five or ſix inches broad, lanceolate egg-ſhaped, acuminate, rather thick, firm, pubeſcent, entire.

CANANI, in *Biography*. See CANANUS.

CANANO, in *Geography*, a town of Naples, in the province of Calabria Ultra; 2 miles S.S.E. of Reggio.

CANANOR, a ſea-port town of Hindooſtan, on the weſtern coaſt of Malabar. It was taken poſſeſſion of by the Portugueſe towards the cloſe of the 15th century; and about the year 1506, Almeyda, the firſt Portugueſe viceroy of India, obtained conſent of the king of the country to build a fort, and to ſecure it with a garriſon. From that time it became a large and populous city, inhabited chiefly by Mahometans, and carrying on a very conſiderable trade. In the year 1663, it was taken by the Dutch, who, conſidering the convenience and importance of its ſituation, eſtabliſhed a factory there. The adjoining country ſupplied abundance of rice, ſugar, pepper, and other valuable commodities; ſo that no leſs than 200 ſhips arrived annually in this port. However, the Dutch ſold it in the year 1770 to the ſultan of Anchediva or Angeoliva, for the ſum of 100,000 rupees. It was taken by the Engliſh, under general Abercrombie, on the 17th of December, 1790. Cananor is diſtant 15 miles N.E. from Tellicherry, and 100 W.S.W. from Seringapatam. N. lat. 11° 55′. E. long. 75° 14′.

CANANUS, John Baptist, in *Biography*, one of the reſtorers and improvers of anatomy, was born at Ferrara, in Italy, in the year 1515, where he acquired ſo much reputation for his ſkill in medicine, that he was invited to Rome by pope Julius III., who made him archiator, and his principal phyſician. On the death of the pope he returned to Ferrara, and purſued his anatomical reſearches. He firſt diſcovered the valves of the veins, which were afterwards more completely deſcribed by Veſalius. The work by which he is known, of which only four complete copies are ſaid to be in exiſtence, is "Muſculorum humani corporis picturata diſſectio," 4to. printed, Haller thinks, in 1543, no date, or place named. The figures, 27 in number, are neatly engraved on copper. They repreſent the muſcles of the upper extremities. In the preface, he promiſes a continuation of the work, which he probably did not finiſh. He died in 1579. Douglas. Bibliog. Haller. Bib. Anat.

CANAPE, John, phyſician to Francis I., in 1542, and public reader in ſurgery to the barbers ſurgeons company at Lyons, publiſhed in 1538, "Le Guidon pour les Barbiers, et les Chirurgiens," 12mo. Lyons. It was much eſteemed in its time, and was ſeveral times reprinted. L'Anatomie des os du corps humain, de Gelian, 1541, Lyons. He alſo tranſlated two of the books of Galen on ſimple medicines, and publiſhed a collection of treatiſes, on different branches of medicine, 1552. Eloy. Dict. Hiſt. Haller. Bib. Anat.

CANAPLES, in *Geography*, a town of France, in the department of the Somme; 10 miles N. of Amiens.

CANARA, a country of Hindooſtan, belonging to the kingdom of Myſore, about 60 leagues in length along the coaſt of the Indian Sea, and from 10 to 30 broad. Its principal places are Mangalore, Barcelore, Onore, and Carwar, which ſee reſpectively. This diſtrict is one of the acquiſitions gained from Tippoo Sultan in 1799. Canara has a peculiar dialect, which extends as far as Goa.

CANAR-ATAN, or *Great Canar*, a village dependent on the city of Cuenca, under the juriſdiction of the province of Quito, in Peru. It is remarkable for the riches contained in the adjacent mountains.

CANARD, in *Ornithology*, among the French, has the ſame application as duck with us, and anas amongſt Latin writers: vide Buffon, and others. In the common phraſeology of France, it literally implies the domeſticated duck.

CANARDER, Fr. is a term of reproach, when applied to a hautbois player; implying, when his reed fails, that he quacks and cackles like a duck.

Canarder, in *Military Language*, denotes to ſhoot, fire, diſcharge, or throw any thing at or on an enemy with advantage, or from a covered, ſecure, and advantageous ſituation, as out of a ſmall turret, guerite, or centry-box, from behind a hedge, dike, or fence, between pickets or paliſades, from walls with embraſures or loop-holes, &c.

CANARDIERE, a ſmall turret, guerite, or centry-box, ſometimes made of wood, and ſometimes of ſtone. Such boxes, or guerites, are occaſionally erected or placed at the ſalient angles of works as places of ſhelter for centinels, and for them to ſee from under cover. They uſed formerly to be conſtructed on caſtles for people to ſhoot, fire, diſcharge, or throw any thing from, unſeen, in unmoleſted ſecurity.

CANARIA, in *Ancient Geography*. See Canary.

Canaria, in *Ornithology*, a ſpecies of Fringilla, familiar to every one by the title of *Canary finch*, or *Canary bird*. The ſpecies is thus defined: bill and body yellowiſh white, with the quill and tail feathers greeniſh. Linn. Fn. Suec. &c.

The canary bird in a ſtate of nature is of a plain grey colour, with the down at the baſe of the feathers black, or blackiſh; the tail is ſomewhat forked, and the legs pale. They inhabit chiefly the Canary iſlands, but are alſo found in other contiguous places. Forſter obſerved them at Cape Verd, Fayal, and Madeira, where they are ſaid to frequent watery places, abounding moſt among the ſedges on the banks of rivulets.

M. Adanſon remarks that the canary bird, which becomes white in France, is at Teneriſſe almoſt as grey as a linnet; a change he ſuppoſes to ariſe from the coldneſs of the climate. The colour is alſo ſuſceptible of conſiderable variation from the diverſity of its food, from captivity, and eſpecially from the intermixtures with other ſpecies. So early as the commencement of the laſt century, Buffon obſerves, that bird-fanciers reckoned in the ſingle ſpecies of canary bird no leſs than nine and twenty varieties, every one of which was ſo diſtinct from each other as to be eaſily pointed out.

It may not prove altogether unintereſting in this place to enumerate the principal varieties of this fancy-bird in the natural order through which they may be traced, beginning with thoſe which approach neareſt to the primitive ſpecies.

Common canary finch, of a grey colour with the down black, as in the wild bird found in the Canary iſlands.

Grey canary finch, with the down and feet white.

Grey canary finch, with white tail.

Common flaxen canary finch.

Flaxen canary finch, with red eyes.

Flaxen canary finch, with plumage gloſſed with a golden hue.

Flaxen canary finch, with the down fair, or unmixed with black.

Flaxen canary finch, with white tail.

Common yellow canary finch.

Yellow canary finch, with the down yellow and unmixed with black.

Yellow canary finch, with a white tail.

Common agate coloured canary finch.

Agate coloured canary finch, with red eyes.

Agate coloured canary finch, with white tail.

Agate coloured canary finch, with the down of the ſame colour.

Common yellow-dun coloured canary finch.

Yellow-dun coloured canary finch, with red eyes.

Yellow-dun coloured canary finch, with plumage gloſſed with a golden hue.

Yellow-dun coloured canary finch, with down of the ſame colour.

White canary finch, with red eyes.

Common variegated or ſpangled canary finch.

Variegated canary finch with red eyes.

Canary finch, variegated with fair or flaxen colour.

Canary finch, variegated with flaxen colour, and having red eyes.

Canary finch, variegated with black.

Canary finch, variegated with black and fine yellow, and having red eyes.

Canary finch, regularly ſpangled with black and fine yellow.

Creſted canary finch.

Canary finch entirely of a full yellow.

Canary finch of a yellow colour, mixed with browniſh grey or greeniſh; which laſt, Dr. Latham obſerves, he has frequently ſeen in Chineſe drawings, but whether they were caged birds or not he was unable to aſcertain.

The above-mentioned kinds of canary birds are again ſubdivided into an amazing number of varieties, ſome of which are remarkable for beauty, and others are no leſs eſteemed for rarity, or melody of ſong. All theſe may, however, be comprehended under two general heads, the variegated kinds, and thoſe with the plumage plain; or, as it ſeems they are denominated in London by bird-fanciers, the *ſpangled*

*gled* and the *gay birds.* Writers obſerve that the white canary finches are never variegated, neither are the citron coloured; but when the latter have attained the age of four or five years, the extremities of the wings and tail become white. The grey are not of an uniform colour, for there are feathers more or leſs grey intermixed in their plumage, and in many of thoſe birds the grey is lighter or darker, and more or leſs inclining to brown or black. The agates are of an uniform colour in general, but liable to vary in the intenſity of their hues. Thoſe inclining to a cream colour are ſtill more uniform; the yellow is conſtant both in the ſame bird, and in different individuals. In the variegated or ſpangled birds thoſe that are of a jonquil yellow are tinged with black, and there is generally a ſpot of black on the head. There are variegated individuals with all the ſimple colours above-mentioned, but thoſe of the jonquil colour are ſuch as are more commonly variegated with black.

Theſe varieties are not the ſpontaneous offspring of the common canary finch; but of that bird croſſed with the *Venturon,* and *Cini,* or Serin, two ſpecies very nearly allied to the canary finch, and both which inhabit the ſouth of Europe. It is by this means, as well as by pairing the canary finch with the goldfinch, linnet, yellow-hammer, chaffinch, and even the domeſtic ſparrow, that ſo many varieties are produced. The canary bird proves fertile with the ſiſkin and goldfinch, but in this caſe the produce for the moſt part proves ſterile: the pairs ſucceed beſt when the hen bird is the canary, and the cock is of the oppoſite ſpecies. Indeed it has been remarked that the male canary bird will not aſſimilate with the females of any of the before-mentioned ſpecies, and that the croſs breed can only be procured by means of the hen canary. The two birds with which the canary intermingles its breed the beſt, as already ſtated, are the Serin, or *Fringilla Serinus,* and Venturon or Citril, *Fringilla Citrinella.* The ſerin is a bird of ſmall ſize, being rather leſs than the common linnet. Its upper mandible is brown, the under, whitiſh: the plumage above, brown, mixed with yellowiſh green; beneath, greeniſh yellow, and having the ſides marked with longitudinal ſpots of brown: the wings are marked with a greeniſh band: quills and tail brown, edged with greeniſh grey, and the legs brown. This kind is found not only in Italy, but in Greece, in Turkey, Auſtria, Provence, Languedoc, Catalonia, and probably in all the climates of that temperature. There are, however, certain years in which it is very rare, even in the ſouthern provinces of France. Its ſong is agreeable and varied, but the ſong of the female is inferior to that of the male. The citril finch is larger than the venturon, and has a louder note; it is indeed remarkable for the brightneſs of its colour, and for the ſtrength and variety of ſong. The female is ſomewhat larger than the male, has leſs of the yellow in its plumage, and does not ſing ſo well, or rather anſwers him, as it were, by monoſyllables. It is found in Provence, Dauphiny, Geneva, Switzerland, Germany, Italy, and Spain. In Burgundy it is known by the name of the canary. The plumage on the upper parts is of a yellowiſh green, ſpotted, or variegated with brown; beneath greeniſh yellow: wings duſky and greeniſh, and the legs fleſh colour. We conceive it right to be thus particular in pointing out the characters of the two latter birds, ſince they have been moſt commonly confounded as varieties of the canary finch, which alone is found in the Canary iſlands; and from which they differ ſpecifically, although in general appearance and manners of life they nearly aſſimilate. It is with thoſe two primitive ſpecies that the canary bird is commonly croſſed with moſt ſucceſs, and from the union of which many of the more eſteemed varieties of the common canary bird are produced. They are reared chiefly by the Germans and Italians, both of whom are celebrated for their ſkill in improving the natural notes of the canary bird by tuition. Moſt of the canary birds, we are told, that are imported from the Tyrol, have been brought up by parents, the progenitors of which were inſtructed by the nightingale. Our Engliſh canary birds have commonly more of the tit-lark note. The principal place for breeding canary birds is Inſpruck and its environs, from whence they are ſent to the Levant, and every part of Europe.

Canary birds are bred in large quantities, both for ſale and amuſement, in England, as well as in Germany, France, and other countries; and in each of theſe countries they have, by beſtowing due attention to the ſubject, very much improved the breed beyond thoſe imported from the Canaries. They are of different colours, yellow, white, buff, grey, and green, with an endleſs variety of combinations ariſing from the different ſhades of colour in the parent birds. Thoſe brought from Germany are generally variegated, or mottled, and are the leaſt valued, becauſe the heat of the ſtoves, generally uſed to warm the houſes in that country, renders the birds bred there tender and ſhort-lived; German birds ſeldom living above two or three years in this country: whereas the canary birds bred in England in the uſual way are ſaid to live eight or ten years. Olina tells us they commonly live 10 or 15 years; Salerne ſays 18, and we have known individuals that have ſurvived for a ſtill longer term of years.

The cock of the German kind is highly valued for its ſinging, having a very ſweet note, which it continues for ſome time in one breath without intermiſſion; and raiſes higher and higher by degrees, with great variety. In this bird the fore part of the head, the throat, the pinion of the wing, and the rump, in the cock bird, are of a brighter yellow than in the hen, which mark will hold good in all the canary birds, of whatever kind they may be. The cock is alſo bigger than the hen, his carriage more ſprightly and majeſtic, and he is obſerved frequently to extend his neck and head in a very briſk and lively manner. The hens ſing indifferently, inſomuch indeed as ſcarcely to deſerve the name of ſinging. Whenever the cock ſings, his throat may be ſeen to ſwell, and play all the while he is warbling, but in the hen there is no ſuch motion. The Hon. Daines Barrington has written an elaborate treatiſe upon the notes of ſinging birds, in which thoſe of the canary bird are treated upon at ſome length, and which may be conſulted with much ſatiſfaction by the curious reader. Vide Phil. Tranſ. v. 63. See SONG *of birds.*

Among a variety of other ſorts, there are two kinds of canary birds in particular that are much eſteemed among breeders; namely, thoſe birds which are all yellow, and thoſe which are mottled and have a yellow crown; the former, in the breeding ſtyle, being called gay birds, and the latter ſpangled, or fancy birds. The fancy breed are eſteemed the ſtrongeſt, and have the boldeſt ſong. Careleſs breeders often match a gay with a fancy bird, and then the produce, partaking of both kinds, are called mules, being foul irregular birds, and of no value for feather, though they may prove as good as any for ſinging. If you propoſe to breed gay birds, chooſe the cock and hen of a clear uniform yellow colour, without being ſpotted with foul feathers; for theſe indicate that the breed has ſome time before been croſſed. There are ſeveral ſubſcription ſocieties in London, which raiſe annual premiums for thoſe who rear the fineſt birds, and who have a pattern bird painted, or engraven and coloured, as a ſtandard of perfection, with his various characters explained in technical terms. The principal teſt of a good fancy bird conſiſts in his having a clean cap, i. e. the crown of his head defined by a horizontal line at the level of his eyes, and beak, is to be of a clean yellow or white, without being broke or ſpotted with foul feathers, as a ſingle feather of this deſcription is conſidered as a drawback from his perfection, though this degree of perfection is ſeldom found. Add to this, that his back, wings, and tail ought to be as clear from yellow or white feathers. The finer he is mottled on the back, and clearer yellow he is on the belly, the handſomer he will be eſteemed. Theſe general characters are equally requiſite in the hen as in the cock, beſides which there is a caſual variety in fancy birds, diſtinguiſhed either as mealies or junks; the mealy birds being thoſe whoſe crown and bellies are of a clean white or pale yellow, and the junks ſuch as have their crown, and belly of a deep yellow. The fine ſpangled ſort, commonly called French canary birds, and the mealy ones, are the beſt to breed with for thoſe who are very curious; becauſe a ſpangled cock with a mealy hen will produce a more regular ſpangled feather than if the cock and hen were both ſpangled, as they would then breed too high upon the yellow.

When individuals of an uniform colour are paired together, their young are of the ſame colour; a cock and hen that are grey generally produce grey birds; but if a male grey is put to a female white, or male white to a female grey, the brood will be more beautiful than the parents; and as the numbers that may be croſſed by ſuch combinations are inexhauſtible, we can at all times produce varieties in ſhade and tint, that have not appeared before. The mixtures that may be made of the ſpangled birds with thoſe of an uniform colour increaſe ſtill more the number of combinations that may be produced; and thus varieties in the ſpecies may be multiplied without end. It likewiſe often happens, that without the aſſiſtance of fancy birds, we have pretty little variegated birds which owe their beauty to the mixture of different colours in their parents or progenitors, ſome of which either by their father or mother's ſide may have been variegated.

With regard to the mixture of other ſpecies with the canary bird, the following obſervations have been collected. The birds that come from the junction of the citril, the ſiſkin, and the goldfinch, with a hen canary bird, are generally ſtronger than thoſe from a cock and hen canary bird. They ſing longer; and their voice is more ſonorous and ſtrong, but they are taught with difficulty; the greater part always whiſtle imperfectly, and it is ſeldom one can be found that is able to repeat a ſingle air correctly, or without miſſing.

When we wiſh to procure birds from a mixture of the goldfinch with a hen canary bird, the former muſt be two years old, and the latter one; becauſe the canary bird comes ſooner to maturity than the goldfinch, and in general they ſucceed beſt when they have been bred up together. But this is not abſolutely neceſſary; neither will the hen that has formerly hatched with a cock of its own ſpecies always refuſe the male of another ſpecies, as father Bougot had an opportunity of aſcertaining. "I happened (ſays Bougot) to put four male canary birds to eight females of the ſame ſpecies; ſome bad ſeeds poiſoned three of the males, and all the females loſt their firſt eggs: I reſolved to ſubſtitute three male goldfinches taken in a trap in place of the three dead canaries, and I put them into the cage about the beginning of May. Towards the end of July I had two neſts of mongrels, which ſucceeded to admiration; and the following year I had three broods with each goldfinch and hen canary bird. Theſe laſt in general do not breed with the goldfinch till they are from a year to four years old, and ſeldom after, while with their own ſpecies they continue to hatch for nine or ten years. The common variegated female alone will breed with the goldfinch beyond her fourth year. A goldfinch muſt never be let looſe in an aviary, for he deſtroys the neſt and breaks the eggs of the other birds." Hence we perceive that the hen canary birds, although accuſtomed to the males of their own ſpecies, will yield to the careſſes of the goldfinch, and will breed with theſe birds ſucceſsfully. Their union with theſe is even as fruitful as with their own natural males, ſince they lay three times in the year with the goldfinch. It is not ſo in the union of the male linnet with the hen canary bird; there being in that caſe only one brood, or very ſeldom two in the courſe of the year.

The baſtard birds, which proceed from the canary, and the ſiſkin, goldfinch, and ſome others, are by no means ſterile, but mongrels that can pair and propagate, not only with the goldfinches or the canary birds indiſcriminately, but alſo among themſelves, and produce offspring that can pair and perpetuate their varieties. But it muſt be owned that the produce of theſe mongrels is not ſo certain nor ſo numerous by any means as in the pure or unmingled ſpecies: they ſeldom hatch more than once in a year, and often lay eggs that are addled. Their ſucceſsful production depends on many little circumſtances that cannot be diſcovered, far leſs pointed out. It is ſaid, that among the croſs breeds there are always many more males than females. A female canary bird and a goldfinch, paired by Bougot, produced, in the ſame year, at three hatchings, nineteen eggs that were all fertile; among which there were only three females, the remaining ſixteen being all males. When a perſon wiſhes to pair the canary bird with the goldfinch, it will be beſt to take young goldfinches of ten or twelve days old from the neſt, and put them into a neſt with canaries of the ſame age. He ſhould feed them together, and leave them in the ſame cage, accuſtoming the goldfinch to the ſame food as the canary bird. It is uſual to put a cock goldfinch to a hen canary bird, as they pair more eaſily, and proſper better than the cock canary bird and hen goldfinch. It muſt, however, be obſerved, that the brood in the firſt caſe is later, becauſe the cock goldfinch does not pair ſo quickly as the cock canary. But when the female goldfinch is put to a male canary bird, the pairing takes place much ſooner. To ſucceed, a male canary bird is never to be put into a cage where there are females of its own ſpecies, for then he will prefer theſe to female goldfinches.

The union of the male canary with the female ſiſkin proſpers exceedingly well. A female ſiſkin, confined in an aviary for nine years, was known to have for the firſt five years three broods annually, and for the remainder of the time two broods a year, all of which proſpered. Linnets and canary birds have been put together, but they ſeldom breed unleſs the cock linnet be put with the hen canary bird; the female linnet will not even make a neſt, but drops a few eggs in the cage, which are generally addled, ſo that it is needleſs almoſt to compel the hen to ſit upon them. The chaffinch and yellow hammer are, with great difficulty, made to pair with the canary bird. A female yellow hammer has been left with a male canary for three years, during all which time the female laid only addled eggs; and it is juſt ſo with the female chaffinch, but the cock chaffinch and yellow hammer with the hen canary bird have produced ſome fertile eggs.

It follows from hence, and various other facts, that the ſiſkin alone will breed with the canary bird equally well, whether male or female; the hen canary bird produces likewiſe eaſily enough with the male goldfinch; not quite ſo eaſily with the male linnet; and laſtly, that it will breed, though more reluctantly, with the males of the chaffinch, the yellow hammer, and ſparrow, while the male canary is incapable of fecundating the females of any of the laſt, or at leaſt that the latter very rarely ſucceeds when paired with them.

The diſpoſitions of canary birds are extremely variable. There are ſome cocks that are always melancholy, and even ſullen, ſinging ſeldom, and then in a diſmal ſtrain; they are long in learning, and learn at laſt, but imperfectly, what you teach them, and that little which they acquire they very ſoon forget. They are often ſo uncleanly, that their feet and tail are conſtantly dirty; and they do not pleaſe the female, whom they never regale with their ſong, not even when their young firſt appear. There are others ſo wicked that they will kill the hen they are put to, and the only way to tame them is to give them two females, who join for their common defence, and when they have once vanquiſhed by force, the male becomes tamer, and they enſure their conqueſt afterwards by tenderneſs and love. Some of the males are ſo ferocious as to break and eat the eggs when the hen has laid them; or, if this unnatural father allows her to hatch them, the young are ſcarcely excluded from the ſhell of the egg, than he ſeizes them with his bill, drags them from the neſt, and kills them. Others are ſo wild and ungovernable, that they will neither allow themſelves to be touched nor careſſed; they muſt be left at liberty, and cannot be treated like the others: if they are meddled with in the leaſt they will not breed; their eggs muſt not be touched, nor taken away; and they will not hatch if they are not ſuffered to pair or build as they pleaſe. And laſtly, there are ſome of an indolent diſpoſition; ſuch, for example, are the grey ones; theſe never build, and the perſon that attends them muſt make a neſt for them. All theſe tempers are very diſtinct, and very different from favourite canary birds that are well-tutored: theſe are always gay, always ſinging, agreeable, of a happy diſpoſition, and endowed with the beſt inclinations.

The bad diſpoſition of the canaries frequently proceeds from miſmanagement. When they break their eggs and kill their neſtlings, they are oftentimes governed by the impulſe of impetuous love, and it is to enjoy the female that the male drives her from the neſt and deſtroys the tender objects of her affection. Accordingly, the beſt means of making ſuch birds hatch is not to put them into different cages. It is better to place them in a room well expoſed to the ſun; and to the eaſt in winter, where there are many hens and only few cocks, for then they will enjoy themſelves more, and multiply better. When a hen ſits, the cock finds himſelf another mate, and does not diſturb her. Beſides, the cocks have many quarrels among themſelves from jealouſy; and when they ſee any one ſo ardent as to torment the female and attempt to break the eggs, they beat him ſo ſeverely as to puniſh him effectually for his temerity.

When the canaries are about to build, they ſhould be furniſhed with lint, or ſhreds of linen, hair of oxen, moſs, and very ſmall and dry ſtraw. Goldfinches and ſiſkins, if put with hen canary birds, when mule birds are wanted, prefer ſmall ſtraw and moſs, but the canary birds like hair and lint: theſe ſhould be cut very ſmall, for fear the threads ſhould entangle the feet of the hen, and cauſe her to pull the eggs from the neſt as ſhe riſes from it.

For feeding them, you muſt place in the room a hopper, pierced all round ſo as to admit their heads, filled with a portion of the following compoſition: three quarts of rape-ſeed, two of oats, two of millet, and two of hemp-ſeed. Every twelve or fourteen days the hopper is to be filled, taking care that the ſeeds are clean and well winnowed. This food is proper as long as they have only eggs; but the evening before the young are excluded, they muſt have a dry cake kneaded without ſalt, which may be left till it be eaten, and then you may give them eggs boiled hard; a ſingle hard egg, if there are but two cocks and two hens, or more, in proportion to the number of birds. They muſt have no vegetables while breeding, as that would weaken the young too much; but, in order to vary their food a little, give them every third day, on a plate inſtead of the dry cake, a piece of white bread dipped in water, and preſſed with the hand; this bread not being ſuch ſubſtantial food as the cake will prevent them from growing too fat when hatching. It will likewiſe be proper to give at the ſame time ſome poppy ſeeds, but only once in two days, for fear of heating them too much: ſugar biſcuits generally produce this effect, which is followed by another ſtill more hurtful; for when they are fed on biſcuit they often lay addled eggs, or bring weak and ſickly young. While they have young, it is recommended to boil their rape ſeed, to deprive it of its acrimony.

After the eggs are laid, give the canary birds plantain and lettuce ſeed to purge them. The food of the neſtlings, when hatched, muſt be prepared: it ſhould be a paſte compoſed of boiled rape ſeed, a yolk of an egg, and crumb of the cake mixed, and kneaded with a little water, which is to be given to them every two hours. This paſte muſt not be too liquid, and, for fear of its turning ſour and injuring the birds, it ſhould be renewed every day till the young can feed themſelves.

Canary birds are diſtinguiſhed by different names, according to their age. Such as are about three years old, are called *runts;* thoſe above two, are named *eriſſs:* thoſe of the firſt year, under the care of the old ones, are called *branchers:* thoſe which are new flown, and cannot feed themſelves, *puſhers;* and ſuch as are brought up by hand, *neſtlings*.

The brood of birds in a ſtate of captivity is not ſo conſtant, but is, perhaps, more numerous than it would probably be in a ſtate of native freedom; for there are hens who will hatch four, or even five times a year, laying four, five, or ſix, and ſometimes even ſeven eggs at a time; in general, they have three broods, and the moulting prevents their having more. There are hens, however, that hatch while they moult, provided they begin to ſit before that time. Birds of the ſame neſt do not all begin to moult at the ſame time. The weakeſt are the firſt to undergo that change; the ſtrongeſt are often a month later. The moulting of jonquil canary birds is more tedious, and generally more fatal than that of the others. The hens of theſe jonquil birds lay only three times, with three eggs each time; the light-coloured ones, both cock and hen, are too delicate, and their brood ſeldom proſpers. The cream-coloured have ſome repugnance to pairing with one another, and in a large aviary it almoſt conſtantly happens, that a cream-coloured male will make choice of a female entirely of another colour. In general the white ones, however, pair, build, and hatch together, and commonly ſucceed better than when a white one is paired with another of a different colour.

Notwithſtanding the difference in the diſpoſition, temperature, and fertility of theſe birds, the time of incubation is the ſame in all. They uniformly ſit thirteen days, and when it happens a day leſs or more, it is owing to ſome accidental circumſtance; cold retards the excluſion of the young, and heat accelerates it. Accordingly, it happens ſometimes, that the firſt ſitting in April laſts thirteen days and an half, or fourteen days, if the air is at that time cold; on the contrary, the third hatching, which happens during the great heats of July or Auguſt, laſts only twelve days and a half. The bad eggs ought to be ſeparated from the good; but in order to know them certainly, you ſhould wait till they have been ſat upon for eight or nine days, then take each egg by the two ends for fear of breaking them, and hold them againſt the ſun, or a lighted candle; thoſe which appear clear are to be rejected as it would only fatigue the hen to no purpoſe to leave them in the neſt. In thus ſeparating the clear eggs from the complement of three neſts, we may ſelect only ſufficient to make up two of them; and the third hen being releaſed from ſitting, will proceed to lay again. It is a practice much recommended by bird-fanciers, to take away the eggs as the hen lays them, ſubſtituting an ivory one in the place of each, that the whole may be hatched together. When the laſt egg is laid, the ivory ones are removed, and the others replaced. In general, the time of laying is in the morning, about ſix or ſeven o'clock; it is ſaid, when this happens an hour later, it is owing to the hen's being ſick; the eggs being thus laid in regular ſucceſſion, it is eaſy to take them away the moment they are laid. However this practice is more adapted to our own convenience than to that of the bird, and is contrary to the economy of nature: it cauſes the mother to part with a great deal of heat unneceſſarily, and burdens her at once with five or ſix young which incommode her more than they give her pleaſure, while when ſhe ſees them come ſucceſſively one after the other, her pleaſures are multiplied, and her ſtrength and courage ſupported; accordingly, ſome very intelligent bird-fanciers aſſert, that the natural way has always ſucceeded better than the above-mentioned practice.

In their native country, canary birds haunt the banks of little rivulets and other watery places; we ſhould not, therefore, ſuffer them to want water, either to drink or bathe in. As they are natives of a very mild climate, they muſt be defended from the rigour of winter, although from long habit, they are now ſo far naturalized to our climate, as to live very well during the winter in a room without fire: ſome breeders accuſtom them even to live all the winter in a room with the window or windows open, and only guarded with a net-work to prevent their eſcape.

It is ſeldom that canary birds brought up in a chamber fall ſick before hatching; ſometimes a few cocks will over-eat themſelves and die; if the hen grows ſick while ſhe is ſitting, her eggs muſt be taken away and given to another; for though ſhe ſhould get better ſoon, ſhe will not return to her neſt. The firſt ſymptom of ſickneſs, eſpecially in the cock, is melancholy; whenever he is obſerved to loſe his natural gaiety, he muſt be put in a ſeparate cage, and placed in the ſun in the ſame room with the hen. If his feathers appear rough, you muſt look if he has not a pimple on the rump; this the bird ſometimes opens with his bill, but if not, it ſhould be pricked with a large needle, and the wound anointed with ſaliva, without mixing any ſalt with it, which would ſmart it too much. The moſt general cauſe of ſickneſs is too abundant, or too rich food; when theſe birds are made to breed in a cage or cloſet, they often eat too much, or ſelect the ſucculent food intended for the young, and hence ariſe the ill effects of repletion, or inflammation. By keeping them in a room, this may be in a great meaſure prevented; becauſe, being among a great number, they hinder one another from eating to exceſs. A cock who eats for a long time is ſure to be beaten by the other males; and the ſame is the caſe with the hens; theſe quarrels give them exerciſe, temperance, and occupation; and it is chiefly on this account that they are ſeldom or never ſickly in a chamber during the breeding time; it is only after hatching that infirmities and diſeaſes attack them. The greater part of them become afflicted with the pimple before mentioned, and afterwards all of them are ſubject to moulting. Some ſupport this change of ſtate extremely well, and do not fail to ſing a ſhort time every day, but moſt of them loſe their voice, and ſome even die. When the hens have attained the age of ſix or ſeven years, they moult with difficulty, and many of them die. Young canary birds moult early in the year: about ſix weeks after they are hatched they become melancholy, appear rough, and put their head under the wing. Their down falls in this firſt moulting, and in the ſecond, the following year, the large feathers, including even thoſe of the wings and tail, fall off. Cold weather is unfavourable to the canaries while moulting, and they would all die at this time, were they not kept in a temperate, or rather in a warm place. The uſual time of moulting is about ſix weeks or two months.

The moſt fatal, and common diſeaſe that the young canary birds are ſubject to, is what is called the ſurfeit, in which their bowels ſeem to deſcend to the extremity of the body. The inteſtines are ſeen through the ſkin in a ſtate of inflammation, redneſs, and diſtention; the feathers on that part fall off, the bird grows emaciated, gives over eating, though he ſits by his meat, and dies in a few days. The cauſe of this diſeaſe is the too great quantity, or ſucculent quality of the food. All medicines are fruitleſs; diet alone can ſave a few out of a number of birds thus affected. They muſt be put into ſeparate cages, and nothing given to them but water, and lettuce-ſeed; this food is cooling and purgative, it tempers the ardour that conſumes them, and ſometimes occaſions evacuations that ſave their lives. In ſhort, we may obſerve, that this diſeaſe proceeds ſolely from our method of rearing theſe birds. We ought, therefore, to be particularly cautious of over-feeding them, when we bring them up: boiled rape-ſeed, a little groundſel without ſugar, or biſcuit, and in general rather too little than too much food is to be recommended.

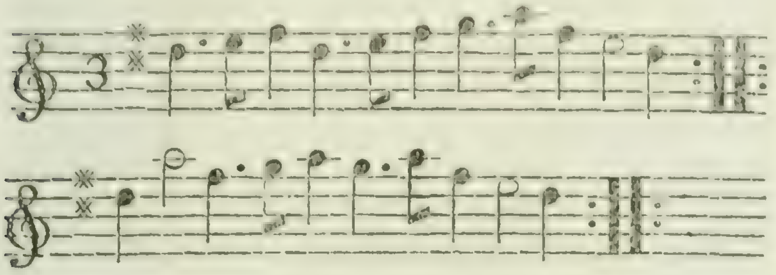
When the canary bird utters a faint and frequent cry, which ſeems to iſſue from the bottom of his ſtomach, he is ſaid to be aſthmatic; he is alſo ſubject to a ſort of extinction of the voice, eſpecially after moulting. The aſthma is cured by adminiſtering plantain ſeed, and hard biſcuit ſoaked in white wine, and the voice may be reſtored by giving him for food the yolk of eggs mixed with crumbs of bread, and for his drink, water in which liquorice root has been ſliced and ſteeped, or if boiled in it, ſo much the better. Canary birds are likewiſe affected with ulcers in the mouth, which are ſuppoſed to proceed from a ſuperabundance of ſucculent food, as in the former caſes: theſe ulcers commonly occaſion an inflammation in the throat, and palate, which can only be cured by adminiſtering a cooling diet, and for this purpoſe nothing can be better than lettuce-ſeed, with a few ſeeds of the melon bruiſed, and infuſed together in water. The impoſthume is another diſorder to which the canary birds are liable: the moſt approved medicine for this diſorder, we are told, is to anoint the top of the head for two or three days with an ointment made of freſh butter and capon's greaſe melted together. After anointing the head three or four times, it ſhould be examined, to ſee whether the part of his head affected be ſoft; and if ſo, open it gently and let out the matter, which will be like the yolk of an egg. When this is done, anoint the wound, and the bird will ſoon be cured. Unleſs this precaution be taken, the canary birds afflicted with this diſorder are very apt to fall down ſuddenly and expire.

Theſe birds are alſo infeſted with a peculiar ſort of louſe, and ſcab, owing to the ſlovenly manner in which they are kept by ſome people. Care ſhould be therefore taken to have them always clean, to give them water to bathe in occaſionally, to be choice in their food, and never to put them into cages of old wood. Thoſe cages it has been recommended, to have made either of walnut-tree, or oak with bars of wire. Cages of the uſual cylindrical form are objected to as being improper, ſince they allow the birds very little room to walk in, and without this exerciſe they become melancholy, or at leaſt, loſe a conſiderable ſhare of their natural vivacity: the cages that are conſtructed of a lengthened form, high, and narrow, are the beſt adapted to the purpoſe of breeding and rearing this beautiful ſong-bird, when the breeder cannot devote a room to that object alone.

CANARIENVOGEL, according to Friſch the canary bird *Fringilla canaria*.

CANARIE, Fr. a quick dance in jig time. The word is twice uſed by Shakeſpeare,—"*Canary* to it with your feet."—*Love's Labour loſt.*—"And make you dance *canary* with ſpritely fire and motion."—*All's Well.*

Merſenne gives a ſpecimen of the kind of movement. He ſays the cabriolles are rapid, and the figure extremely difficult.



Purcell has *canaries* in his muſick to Diocleſian. The tune is ſaid to come originally from the *Canary* iſlands.

CANARII, in *Ancient Geography*, a people of Africa, who inhabited the diſtrict towards the ſouth-eaſt of Mount Atlas. Pliny mentions them, and ſays, that they eat the fleſh of dogs.

CANARINA, in *Botany*. Linn. Mant. 225. Schreb. 603. Willd. 689. Juſſ. p. 164. Vent. vol. 2. p. 470. Claſs and order. *Hexandria monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Campanulaceæ*, Juſſ. Gen. Ch. *Cal.* Perianth ſuperior, ſix-cleft, permanent; ſegments lanceolate, recurved. *Cor.* monopetalous, bell-ſhaped, ſix-cleft, nerved; nectary of ſix valves, equal, covering the receptacle, diſtant. *Stam.* Filaments ſix, awl-ſhaped, ſpreading outwards, originating from the valves; anthers pendulous from the tip. *Piſt.* Germ inferior, hexagonal; ſtyle conical, ſhort; ſtigma longer than the ſtamens, club-ſhaped, ſix-cleft. *Peric.* Capſule ſix-angled, obtuſe, ſix-celled. *Seeds* numerous, ſmall. Eſſ. Ch. Calyx ſix-cleft, corolla ſix-cleft, bell-ſhaped, ſtigma, ſix-cleft.

It differs from Campanula only in number; a difference which, if allowed to be a ſufficient generic diſtinction, will baniſh many ſpecies from the genera in which they have been very naturally placed, and have long quietly ſtood. Linn. Mant. 225. Willd. Mart. Lam. Ill. Pl. 259. Bot. Mag. 144. Sp. 1. C. *campanula*, (C. canarienſis, Linn. Sp. Pl. 29. Tourn. 109. Pluk. Alm. tab. 276. fig. 1.) "Stem erect; leaves halbert-ſhaped, in threes or oppoſite." *Root* perennial, ſpindle-ſhaped. *Stem* three feet high, herbaceous, erect, rather feeble, round, even, knotty, branched; branches two or three from each knot; upper ones longer, dichotomous at the end; little branches alternate. *Leaves* on the ſtem by threes, on the branches oppoſite, petioled, unequally toothed, even, veined. *Flowers* from the forks of the upper branches large, peduncled, drooping; corolla reddiſh-yellow, or orange, brighter at the bottom, with a yellow eye; each ſegment marked with three purple branched nerves; anthers yellow. A native of the Canary iſlands, whence the genus, though not very properly, has derived its name. 2. C. *Zanguebar*, Lour. Cochinch. 195. "Stem climbing: leaves halbert-ſhaped alternate." *Stem* ſhrubby, round, even, branched. *Leaves* heart-halbert-ſhaped, quite entire, ſmooth, veined, petioled. *Flowers* ſolitary, lateral: corolla pale-coloured. *Capſule* ſomewhat egg-ſhaped, ſharp at the baſe, ſix-nerved, opening at the baſe, ſeeds heart-ſhaped, compreſſed, ſurrounded by a turbinate ring, odorous. A native of Zanguebar on the coaſt of Africa.

*Propagation and Culture.* The firſt ſpecies only has been cultivated in Europe. It is propagated by parting the roots, which ſhould be done in July, ſoon after the ſtalks are decayed. It ſucceeds beſt in a light ſandy loam, with a fourth part of ſcreened lime-rubbiſh. The pots ſhould at firſt be placed in the ſhade, and unleſs the ſeaſon be very dry, ſhould not be watered. About the middle of Auguſt they ſhould be placed under the hot-bed frame, and as the nights grow cool, covered with the glaſſes. When the ſtalks appear, the plants ſhould be ſometimes, but not often, refreſhed with a ſmall quantity of water. About the middle of September they ſhould be removed into a dry airy glaſs-caſe, where they may enjoy the free air in fine weather, and yet be ſcreened from cold. They flower from January to March, when they ſhould be frequently watered. In ſpring, when the ſtalks begin to decay, the pots ſhould be ſet abroad in the ſhade and not watered. Miller.

CANARIUM, from *canis*, *dog*, in *Antiquity*, a Roman ſacrifice, wherein dogs of a red and ruddy colour were ſacrificed, for a ſecurity of the fruits of the earth againſt the raging heats and diſorders of Sirius in the dog-days.

CANARIUM, in *Botany*, (from its vernacular name Canari, in the Malay language) Linn. Mant. 127. Schreb. 1516. Juſſ. 370. Gært. 605. Claſs and Order. *Diœcia pentandria*. Nat. Ord. *Terebintaceæ*, Juſſ.

Gen. Ch. Male. *Cal.* Perianth two-leafed: leaves egg-ſhaped, concave, permanent. *Cor.* Petals three, oblong, reſembling the leaves of the calyx. *Stam.* Filaments five, very ſhort; anthers oblong, the length of the petals.

Female. *Cal.* as in the male: leaves reflexed. *Cor.* as in the male. *Piſt.* germ egg-ſhaped: ſtyle ſcarcely any: ſtigma capitate, triangular. *Peric.* Drupe dry, egg-ſhaped, acuminate, ſurrounded at the baſe with a ſcolloped membrane. *Seed.* Nut egg-ſhaped, triangular, acute.

Eſſ. Ch. Calyx two-leaved. Corolla tripetalous. Stigma nearly ſeſſile. Drupe with a triangular nut.

Sp. 1. C. *commune*. Linn. Mant. 127. (C. vulgare Rumph. Amb. 2. p. 145. Tab. 47.) β. C. Mehembethene. Gært. tab. 102. fig. 1. A reſinous lofty tree. *Trunk* covered with a whitiſh bark; wood whitiſh, tolerably ſolid, but not durable. *Leaves* alternate, unequally winged; common petioles ſtriated; leaflets nine, large, petioled, oblong egg-ſhaped, acuminate, even. *Flowers* whitiſh, ſeſſile, ſtiff, divaricated panicles, which terminate the branches. Gærtner aſſerts that the commune of Linnæus, and the mehembethene are mere varieties of the ſame ſpecies. He has figured the fruit of mehembethene, and given the following deſcription. *Drupe* ſuperior, berried, acuminate-egg-ſhaped; ſkin olive-coloured, thin; pulp ſmall in quantity, full of capillary fibres: ſhell bony, egg-ſhaped, either ſlightly pitted or even, trigonous, three-celled, with three obtuſe teeth at the tip, marked with three obſcure raiſed lines on the ſides, and perforated through its whole length with a thread-ſhaped axillary canal. *Seeds* oblong-egg-ſhaped, two in each cell, only one of which comes to maturity. The drupe of the other variety is a little larger, and the pulp without fibres. The ſhell is more ſharply triangular, and its ſides are perfectly ſmooth, nearly flat, without the middle raiſed line. The fertile cell and ſeed are alſo larger. In the oldeſt ſeeds Gærtner never found the kernel rancid, but always ſweet, with a flavour reſembling that of freſh almonds which, as he obſerves, is the more remarkable, becauſe the cotyledons, when the integument of the ſeed is ſtripped off, ſeem beſmeared with oil, are very ſlippery, and repel water.

A native of the Molucca Iſles and New Guinea. The nuts are eaten by the natives either raw, or made into a kind of bread. An oil is alſo expreſſed from them which is uſed at the table. When eaten freſh they are ſaid by Rumphius to bring on dyſenteries, and to occaſion an oppreſſion of the breaſt. 2. C. *ſylveſtre*, or Nanarium. Rumph. amb. 2. tab. 49. Gært. tab. 102, fig. 3. *Drupe* fleſhy, inverſely egg-ſhaped, round, not trigonous as in the preceding; ſhell egg-ſhaped, ſtony, very thick, obſcurely trigonous, marked with three depreſſed longitudinal lines, to which as many ſmall callous tubercles are joined below the top of the ſhell; cells three, two of which are often abortive, the third very irregular, and lined with a very ſmooth cartilaginous cruſt. *Seed* oblong, trigonous, curved in the form of the letter S, gibbous in contrary directions near each end. The kernel, on account of its ſingular form and brittleneſs, cannot be got out entire, unleſs the ſhell be opened carefully from one end to the other. 3. C. *decumanum*, Rumph. tab. 55. Gært. tab. 102. fig. 2. *Drupe* the largeſt of any in the genus; ſhell oblong-egg-ſhaped, triangular, ſtony, thick, with ſix teeth at the tip; angles prominent, ſmooth, longitudinally furrowed; ſides pitted with numerous oblong depreſſions as if they had been eaten by worms; axillary canal triangular; cells three, large. *Seeds* wanting in the ſpecimen examined by Gærtner. Profeſſor Martin has repreſented the laſt two alſo as only varieties of C. commune: but it is evident, from Gærtner's deſcriptions and references to Rumphius, that he judged them to be diſtinct ſpecies.

Loureiro calls this genus Pimelea, on account of its oily produce, but that name has been given for a ſimilar reaſon to a very different ſet of plants, natives of New Holland and New Zealand. See Pimelea. Loureiro has added to the C. commune of Linnæus, which he calls Pimelea alba, two other ſpecies which he found in Cochin-China and its neighbourhood. 4. C. *nigrum*. Leaves winged; flowers in lateral racemes: nuts two-celled. An oil is extracted from its kernel, not leſs agreeable than that of the olive, but heavier on the ſtomach. 5. C. *oleiferum*. Rumph. vol. i. tab. 54. Leaves pinnated with four pair of leaflets; peduncles lateral, many-flowered; nut one-celled. The drupes are eaten like thoſe of the firſt ſpecies; an oil for the table is likewiſe procured from them. When the bark is wounded, there exudes a yellowiſh, odorous, oily reſin, ſimilar to copal, which is uſed to varniſh houſehold furniture. The ſubſtance called Damar or Dammar in the Eaſt Indies, and uſed for the calking of ſhips, is compoſed of this reſin, mixed with the bark of the bamboo reduced to powder, and a little chalk. It is preferable to all other ſubſtances for this purpoſe with reſpect both to its durability and tenacity, and has not the ſmell of European pitch. Boſc. in Nouv. Dict. The trivial name given by Loureiro to the laſt ſpecies is a bad one, not being at all diſcriminative.

Canarium, in *Conchology*, a ſpecies of Strombus, found in the ſeas and great rivers in the ſouthern parts of Aſia. This ſhell is ſomewhat heart-ſhaped, with the lip round, ſhort, retuſe, and with the ſpire ſmooth. Linn. &c. Length two inches and a half; colour yellow, or brown, with tranſverſe fuſcous angulated lines; pillar ſnowy white. The general contour of the ſhell remarkably ventricoſe.

Canarium of Rumpfius is the ſpecies of Strombus deſcribed by Linnæus under the name of Gibberulus.—Canarium is alſo the name given by Rumpfius to the Linnæan Strombus Urceus, which ſee.

CANARY, in *Geography*, a town of Poland, in the palatinate of Sandomirz; 16 miles W. of Sandomirz.

Canary, *Grand*, ſtill known by the name *Canaria*, given to it by Pliny and Ptolemy; one of the Canary iſlands, from which the general appellation is derived; ſituate between Teneriffe on the weſt, and Forteventura on the eaſt, about 100 miles N.W. from Cape Bojador on the African coaſt. N. lat. about 27°. W. long. 15°.

This iſland is about 100 miles in circumference, and the number of inhabitants amounts to 40,000. Pliny ſays, that it formerly produced a ſort of dates, and pine-apples in great abundance. The ſoil, though light and ſandy, is covered with a rich mould, which produces two harveſts in the year. The wheat and other corn are reckoned very good; ſugar canes are much cultivated; the vines yield thoſe grapes from which is made the wine called ſack, or canary; and the iſland abounds with excellent fruits, ſuch as apples, pears, melons, figs, peaches of ſeveral kinds, and plantains. It has alſo plenty of horned cattle, ſtags, poultry, pigeons, and partridges. Wood is ſcarce. Filtering-ſtones conſtitute an article of traffic from this iſland, as well as from Forteventura. The capital of the iſland, and alſo of the Canary iſlands, is Palma or Canary: the other towns are Galder, Tirachana, and Luz.

Canary, called alſo *Palma*, in Latin *Civitas Palmarum*, and in Spaniſh *Cividad das Palmas*, the capital of the preceding iſland. Although the governor and the chief people of diſtinction commonly reſide at Teneriffe, yet Canary is the ſee of a biſhop, ſuffragan to the metropolitan of Seville in Spain, who uſually reſides in this town, and has a tribunal of inquiſition. The royal audience, or ſovereign council of the Canaries, over which the governor preſides, is held in this town, and receives appeals from all the other iſlands. The revenues of the biſhop, amounting to 10,000l. a year, are almoſt entirely diſtributed in acts of charity through all the iſlands; and the preſent biſhop (ſee Emb. to China, vol. i. p. 117.) joins to this humane diſpoſition, the rigour of eccleſiaſtical diſcipline, and encourages the obſervance of ceremonies of piety, by offers of indulgence to thoſe who practiſe them. This town is ſeated on the ſouth-weſt ſide of the iſland, at a ſmall diſtance from the ſea. Its climate is temperate; its extent about a league in circumference; its cathedral is magnificent; and its houſes, though only one ſtory high, and flat at the top, are generally elegant buildings; it has four convents. The number of inhabitants is eſtimated at 12,000. N. lat. 28° 10′. W. long. 15° 36′.

✗ Canary *Iſlands*, a cluſter or groupe of iſlands in the Atlantic Ocean, ſituate about 150 miles to the weſt of the empire of Morocco in Africa, between N. lat. 27° 15′ and 30°. W. long. 13° and 17° 30′. They are generally ſuppoſed to have been the ſame with the *Inſulæ Beatæ*, or *fortunate iſlands* of the ancients, particularly deſcribed by Ptolemy and the elder Pliny, and ſo called on account of the ſingular temperature of their climate, the fertility of their ſoil, and the excellence of their fruits. Ptolemy, however, if he meant theſe iſlands, has placed them 11° too near the equinoctial, or in the 16th degree of N. latitude, whence ſome have concluded, that this appellation belonged to the Cape de Verd iſlands. But Strabo aſſigns them a ſituation which agrees with the obſervations of modern geographers. Some have derived their name from *canis*, dog, on account of the number of large dogs which were found on the iſland Canaria or Canary, two of which were preſented to Juba, king of Mauritania. Others deduce the origin of the name from the Canaanites, or Phœnicians, who are ſaid to have often ſailed from the continent to Carne, ſuppoſed to be a contraction of Canary. The number of the Canary iſlands has been differently ſtated, both by ancient and modern geographers. Pliny and Ptolemy reckon ſix; Plutarch and others mention only two; modern geographers have generally reckoned 13, excluſive of Madeira, which is at a conſiderable diſtance to the north: but the inhabited iſlands have been reduced to ſeven, viz. Palma, Gomera, Ferro, Teneriffe, Grand Canary, Forteventura, and Lancerota; ſee each reſpectively. To theſe have been added the following ſix ſmall iſlands, viz. Lobos, Roca, Gracioſa, Santa Clara, Allegrança, and Inferno, beſides a cluſter of rocks, called the Salvages, between Madeira and the Canaries. Teneriffe, though not the largeſt, is probably the moſt fertile of the Canary iſlands, and its population amounts to nearly 100,000 perſons. That of the Grand Canary has been already ſtated; that of Palma is eſtimated at 30,000; of Forteventura at 10,000; of Lancerota at 8000; of Gomera at 7000: and of Ferro at 1500: the total according to this enumeration amounts to 196,500: but others reckon the population of Teneriffe at 64,000, and the whole at 140,000. The air of that iſland is pure and temperate, and the ſoil is fertile; the product is wheat, barley, rice, and oats; the excellent canary wine is obtained chiefly from Teneriffe and Palma: Gomera is noted for ſilk; and the tree yielding the juice called dragon's blood is not uncommon. Fruits of various kinds are of excellent quality, and are cultivated in great abundance. Theſe iſlands are well ſupplied with cattle, ſuch as cows, ſheep, goats, and wild aſſes, which run about the mountains in droves; their woods are ſtored with varieties of the feathered kind, of which the canary birds are well known; and the ſurrounding ſeas are ſtocked with ſhoals of fiſh, particularly ſturgeon. All the iſlands have ditches and marſhes filled with water at ſpring-tides, and afterwards evaporated by the heat of the ſun, ſo as to yield a fine ſea-ſalt. Flax, aniſeeds, and coriander are cultivated in the different iſlands. Archil and ſumach grow ſpontaneouſly. See ARCHIL. Kali is found along the ſea-ſhore, and might afford as good ſoda as that of Alicant. The cotton ſhrub and alſo the ſugar-cane are much neglected. Potatoes have within the laſt 30 or 40 years been introduced in theſe iſlands; and at preſent they conſtitute almoſt the chief food of the inhabitants. Wheat and barley are ſown in November and December, and uſually reaped in April and May. The corn is careleſsly raked together, carried home in ſacks on the backs of aſſes, mules, or camels, and then trodden out by cattle, and the grain ſeparated from the chaff by expoſing it to the wind. The lands are not rented in the Canaries: the landholder furniſhes the ſeed and implements of huſbandry, and receives one half of the produce, beſides a certain quantity of wheat for each head of cattle, which he lends to the tenant. Bread is only eaten by the richer inhabitants. The people in general ſubſiſt much on "goffio" which is only parched grain ground by a little hand-mill, of which every cottage poſſeſſes one. Thoſe who uſe better fare have recourſe to ſalt fiſh and potatoes. The poor inhabitants of Palma and Gomera are ſometimes reduced to the neceſſity of making cakes of the roots of the "pteris aquilina," or male fern, which they dig in the mountains. Lupines are a choice food for cattle; but they are previouſly ſoaked in water and boiled with the addition of ſalt. The capital of the ſeven inhabited iſlands is the town of Palma, or Canary, in the iſle of Canary.

Hiſtory gives no certain information with regard to the original inhabitants of theſe iſlands. Some ſay, that they were exiles from Africa, whom the Romans baniſhed thither, after cutting out their tongues, for having blaſphemed their gods. But how perſons, deprived of the organ of ſpeech, could form any language, peculiar to themſelves, and tranſmit it to poſterity, it is not eaſy to conceive; and, therefore, this circumſtance attending their origin is probably fabulous. It is ſaid, however, that all the deſcendants of the ancient inhabitants ſpeak the ſame language, though diverſified into different dialects. Their clothing conſiſted of hides and ſkins; and they inhabited caves and rocks in perfect harmony and union. Their food was the fleſh of horned cattle, dogs, and the milk of goats; and they prepared a kind of pudding, or bread, of milk and triturated corn, called "goſſio," which is now common under the ſame name. The firſt diſcovery, as well as the original ſettlement of theſe iſlands, is involved in conſiderable obſcurity. It appears, however, that they were imperfectly known to the Spaniards, in conſequence of ſome of their piratical excurſions, about the middle of the 14th century. Pope Clement VI. it is ſaid, having preached a ſermon to prove that he had the ſole right of creating kings and beſtowing kingdoms, exerciſed the prerogative, Nov. 15th, A.D. 1344, of creating Lewis de la Cerda, deſcended from the royal family of Caſtile, king of the Fortunate iſlands, ſuppoſed to be the Canaries; though the new monarch was unable to diſcover in what part of the world his new dominions were ſituated. At length, in 1393, or 1395, or, as others ſay, 1405, ſome private adventurers from the coaſt of Biſcay extended their piratical excurſions as far as theſe iſlands; and John de Bethencourt, a Norman baron, obtained a grant of them from Henry III. of Caſtile. Bethencourt, with the valour and good fortune which diſtinguiſhed the adventurers of his country, attempted and effected the conqueſt, and with the conſent of the Spaniſh court, aſſumed the title of king of the Canaries; and the poſſeſſion of them remained for ſome time in his family, as a fief held of the crown of Caſtile. In 1431 the grant of them was confirmed to John II. king of Spain, or Caſtile, by pope Eugenius IV.; and in 1483 Ferdinand and Iſabella, king and queen of Spain, being before poſſeſſed of four of theſe iſlands, conquered the iſland called Grand Canary; and alſo the two remaining iſlands; and by the treaty of peace between Ferdinand, king of Caſtile, and Alphonſo, king of Portugal, it was agreed that theſe iſlands ſhould belong to Spain, in lieu of the ſettlements on the continent of Africa, ceded to Portugal: accordingly, they have all remained in the poſſeſſion of Spain to this day. Thoſe whom the Spaniards found in poſſeſſion of theſe iſlands they denominated Guanches; and the appellation has been tranſmitted to their deſcendants. They are repreſented as gigantic in ſtature and barbarous in their manners. They were idolaters and polygamiſts; and their property was common poſſeſſion. Ignorant of the uſe of iron, they cultivated the earth with the horns of bullocks, and ſheared their ſheep, and ſhaved themſelves, with whetted flints inſtead of inſtruments of iron. Although they were denominated barbarous, they were ſingularly humane, and abhorred the idea of ſhedding blood. When any one of their princes died, they waſhed his body, and placing him erect in a cave, they put a ſceptre in his hand, with two jars by his ſide, one filled with milk, the other with wine, as the neceſſary proviſion for his journey. When Cadamoſto viſited the Canaries in 1445, each iſland was divided into a number of provinces or diſtricts, of which Teneriffe contained nine; but among theſe little ſtates wars overſpread the face of the country with carnage and blood; and yet their military weapons conſiſted merely of ſtones and two kinds of lances, one armed with horn, and the other wood hardened and pointed in the fire. For protection againſt the ſcorching ſun in ſummer, and againſt the inclement cold in winter, they anointed their bodies with a mixture of tallow and the juice of certain plants, which tinged their ſkins with various colours, red, yellow, and green; and both men and women uſed this extraordinary defence and ornament. Each iſland and each ſtate had its peculiar form both of religion and government; although within the ſame ſociety every thing was common; viz. religion, cuſtoms, language, manners, and property itſelf. In Teneriffe there were no leſs than ten different ſects of idolaters,

ters, ſome of whom worſhipped the ſun, and others the moon, and the reſt of the heavenly bodies. Although polygamy was allowed, the virginity of the bride rightfully belonged to the chief; and the parties thought themſelves highly honoured when he claimed his right. Upon the acceſſion of a new prince, it was the cuſtom to ſacrifice a number of young perſons of both ſexes in honour of him, and in order to procure bleſſings upon his reign. This was done by precipitating themſelves from a ſteep rock, after the performance of many abſurd ceremonies, till they were daſhed in pieces by the violence of the fall. The parents of theſe infatuated victims were diſtinguiſhed by the favour of the reigning prince. The preſent Guanches are ſtout and robuſt, though inferior in ſize and ſtrength to their anceſtors. Their complexion is tawny, and their noſes large and flat. Their genius is lively; they are brave, active, and cunning, and are much addicted to war. Their appetite is ſingularly voracious; and they live upon grain formed into cakes with milk and honey; and their food is preſerved in ſkin-pouches, which they ſuſpend to their belts and girdles, and in which they likewiſe bake them in the ſmoke. Some rigidly abſtain from wine and alſo from animal food. Such are their alertneſs and activity, that they run up and down mountains, and ſpring, by means of long poles, from rock to rock with aſtoniſhing agility. In all their conteſts they uſe ſtones, and throw them with a force equal to that of a muſket-ball. Dr. Sprat (Hiſt. of the Royal Society, p. 212, &c.) has related a variety of other curious anecdotes concerning this people. The race of the Guanches, however, is now almoſt extinct. The few who remain in Teneriffe are entitled to ſome very trifling ſtipend, as a price of the ſubmiſſion of their anceſtors, from the court of Spain, which they punctually, and with ſome ſenſations of pride, annually demand. Many of the dead bodies of thoſe Guanches have been found in perfect preſervation, in an erect poſture, placed againſt the ſides of caves dug into the mountains; the bodies being wrapped round with ſeveral folds of goats' ſkins. The total net revenue of the crown, after defraying the expences of adminiſtration, of all the Canary iſlands, amounts to about 60,000l. a year. See TENERIFFE, &c.

CANARY, an iſland of the South Pacific Ocean. S. lat. 1° 51′ 36″. E. long. from Paris 127° 35′.

CANARY *bird*, in *Ornithology*, *Canary finch*. See CANARIA *Fringilla*.

CANARY, in *Agriculture*, a ſort of plant cultivated in ſome of the more ſouthern diſtricts, as Kent, &c. for the ſmall ſeed which it produces. It is obſerved, in the Agricultural Survey of that county, "that there are three kinds of tilths for it; namely, ſummer-fallow, bean-ſtubble, and clover-lay: the laſt the writer conſiders beſt. If the land is not very rich a coat of rotten dung is frequently ſpread for it." But whether manured or not, the tillage neceſſary is to plough the land the firſt opportunity that offers after wheat ſowing is done; and as ſoon as it is tolerably dry in the ſpring, furrows ſhould be made, about 11 or 12 inches apart, and the ſeed ſown broad-caſt about four or five gallons per acre, and well harrowed in. When the blade appears, and the rows are diſtinct, the intervals are immediately hoed with a Dutch hoe, and afterwards, in May or June, the hoeing is repeated with a common hoe, carefully cutting up every weed, and thinning the plants in the furrows, if they are too thick. It is cut in the harveſt, which is always later than any corn crop, with a hook provincially called a *twibil* and a *hink*, by which it is laid in lumps or wads of about half a ſheaf each. The ſeed clings remarkably to the huſk, and in order to detach it the crop muſt be left a long time on the ground, to receive moiſture ſufficient to deſtroy the texture of the envelopement, otherwiſe it would be hardly poſſible to threſh out the ſeed. The wads are turned from time to time, to have the full benefit of the rains and ſun, and thereby render them as dry as poſſible.

It is remarked, that the price of reaping canary in the iſle of Thanet was formerly from ſix to eleven ſhillings per acre, and the prices of threſhing and dreſſing it five or ſix ſhillings the quarter: but at preſent they are conſiderably higher. According to the goodneſs of the land, and the tillage that has been beſtowed upon it, the farmers then expect their returns to be from 25 to 50 buſhels per acre, but the common crop is from 30 to 34. It was formerly the practice to ſow ſucceſſive crops on the ſame land for eight or ten years, but this practice is now juſtly exploded. It is added, that ſowing canary would be a very great improvement to lands which lie convenient for water-carriage to London markets, was it not a crop the farmer ought by no means to depend upon, not only becauſe the return or quantity it yields varies greatly, but alſo on account of the fluctuation in the price of the ſeed in the markets. Some adviſe ſowing this crop in drills a foot aſunder, thinning the plants out afterwards, ſo as to leave them about two inches diſtant in the rows. Three gallons of ſeed in this way are ſufficient for an acre, where a hopper is made uſe of ſo ſet by a ſpring as to deliver the ſeeds at equal diſtances. It ſhould be ſown about the end of February.

The chaff of this ſeed affords a large proportion of good horſe-food.

CANARY-*graſs*, a ſort of graſs which can ſeldom be cultivated with advantage as a meadow or paſture graſs: but one of the kinds of which is grown in ſome diſtricts for the ſeed. See CANARY.

CANARY-*graſs*, in *Botany*. See PHALARIS *Canarienſis*.

CANARY-*weed*. See LICHEN *Roccella*.

CANAS, in *Ancient Geography*, a town of Aſia Minor in Lycia, which was formerly epiſcopal.

CANAS and CANCHES, or TINTA, in *Geography*, a juriſdiction of Peru in South America, in the dioceſe of Cuſco, commences about 15 or 20 leagues S. of Cuſco, and extends about 20 leagues in every direction. The Cordillera divides it into two parts; the higheſt called *Canas*, and the loweſt *Canches*. The latter, by reaſon of the temperature of its air, yields all kinds of grains and fruits; whilſt the former affords paſture for very numerous flocks and herds; and in the meadows between the eminences are fed no leſs than 25 or 30 thouſand mules, brought hither from Tucuma to paſture. Here is a very great fair for theſe animals, to which dealers reſort from all parts of the dioceſe. In the part called Canas is the famous ſilver mine denominated Condonoma.

CANASERAGA CREEK, a creek of North America, which runs north-weſtward into Geneſſee river at Williamſburg, in the ſtate of New York.

CANASIS, in *Ancient Geography*, a town of Aſia, ſeated on the coaſt of the Erythrean ſea, in Carmania, according to the Periplus of Nearchus.

CANASTRON, a promontory of Macedonia, at the extremity of the peninſula of Pallena, between the Thermaic and Toronaic gulfs.

CANATAGUA, a mountainous ridge which paſſes N. and S. between the provinces of Veragua and Panama, in the Spaniſh territories of N. America.

CANATH. See KENATH.

CANATTE CORONDE, a name given by the Ceyloneſe to a peculiar kind of cinnamon growing in that iſland: this is eſteemed the ſecond kind in value, and the name they give to it ſignifies bitter and aſtringent cinnamon. The bark of this kind of cinnamon-tree comes off very eaſily, and is of a very fragrant ſmell when freſh, but it has a bitter taſte. It is not very common in the iſland, and is not eaſily difdiſtinguiſhed on the tree from the beſt cinnamon. The trees which yield the eight different kinds of cinnamon, ſo very various in flavour and virtue, are all ſo like one another, that it requires a great deal of attention to diſtinguiſh them. The root of this kind of cinnamon-tree yields a very fine ſort of camphor. Phil. Tranſ. N° 409. See CINNAMON.

CANAVARIUS DEMETRIUS, in *Biography*, a diſtinguiſhed phyſician, and voluminous writer in medicine, born at Genoa, in 1559, received his education at Rome, where he became extremely popular as a phyſician, and acquired a conſiderable property. He died in 1625. The principal of his works are "De Ligno Sancto Commentarius;" Romæ 1602, 8vo. in which he gives the diſtinguiſhing characters of the genuine wood; a ſpurious kind having found its way into the ſhops, and been uſed in its ſtead, "Ars Medica." Gena fol. 1626. This is a republication of his account of all the diſeaſes incident to the human frame, with the mode of treating them, taken from the moſt approved writers, originally printed in 8vo. at Venice, here much enlarged and improved. Haller, Bib. Med. Eloy. Dict. Hiſt.

CANAVEZ, in *Geography*, a diſtrict of Italy, in the principality of Piedmont, of which Ivrea is the capital.

CANAVEZES, a town of Portugal, in the province of Entre Duero é Minho; 27 miles E. of Porto.

CANAWISQUE, a weſtern branch of the river Tioga, in America, which riſes in Pennſylvania.

CANCALE, a ſea-port town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the diſtrict of St. Malo; celebrated for oyſters: 3 leagues E. of St. Malo. N. lat. 48° 41′. W. long. 0° 31′.

CANCANI, or CANGANI, *promontory of the*, in *Ancient Geography*, is placed by Ptolemy in the iſle of Albion, and is thought to be Braychipult point in Caernarvonſhire.

CANCARELLA ASPARAGI of Valiſn. in *Entomology*, ſynonymous with *cryptocephalus campeſtris* of Fabricius.

CANCELIER, in *Falconry*, is when a light-flown hawk, in her ſtooping, turns two or three times upon the wing, to recover herſelf before ſhe ſeizes.

CANCELLARIUS, in *Antiquity*. See CHANCELLOR.

CANCELLATA, in *Conchology*, a ſpecies of ARCA, the ſhell of which is marked with cancellated ſtriæ, and bearded; the margin gaping in the middle. Schroet. Inhabits the American ocean.

*Obſ.* In its natural ſtate this kind is covered with a moſſy epidermis, or membranaceous coating, beneath which the ſhell is of a ſomewhat fuſcous colour, mixed with white, and beſet on both ſides with four tufts of hair; beaks ſlightly recurved; poſterior depreſſion lanceolate.

CANCELLATA, a ſpecies of NERITA, the ſhell of which is marked with decuſſating ſtriæ and impreſſed dots; ſpine ſlightly clavated; umbilicus gibbous and bifid. This inhabits the coaſts of the American iſlands. Chemnitz.

*Obſ.* This ſhell is white, and obſoletely ſpotted, and is ſometimes marked with rays or a fulvous band.

CANCELLATA, in *Entomology*, a ſpecies of CICADA, found in Denmark. The colour is yellow, with three dots on the ſcutel, and tip fuſcous; wings white and reticulated. Mull. Zool. Dan.

CANCELLATA, in *Ornithology*, a ſpecies of TRINGA, ſeven inches and an half in length, that inhabits Nativity Iſland. Latham calls it the *barred phalarope*. The upper feathers are brown edged with white; lower ones white with tranſverſe duſky lineations; feet pinnated and duſky.

CANCELLATE, in *Botany*, open like lattice-work. A term applied to the involucre in atractilis cancellata, to the capſule of the lily, &c.

CANCELLATUM, in *Conchology*, a ſpecies of BUCCINUM, of a ſmall ſize, mentioned by Seba. The ſhell is glabrous, with ſtreaks and lines that variouſly decuſſate each other. Native place unknown.

CANCELLATUM, a ſpecies of CARDIUM, of ſmall ſize. This kind is reddiſh, thin, roundiſh, with decuſſating ſtriæ. Gualt. &c.

CANCELLI, in *Building*, lattices, or a ſort of windows made with croſs bars of wood or iron, chequer-wiſe.

The term is alſo applied to the baluſters or rails which compaſs a court of juſtice, a communion-table, or the like.

CANCELLI, in a *Military Senſe*, the ſame with BARRIER.

CANCELLING, in the *Civil Law*, an act whereby ſome former deed is rendered null and void.—This is otherwiſe called *reſciſſion*. The word comes from the Latin *cancellare*, *to encompaſs*, or *pale a thing*. In the proper ſenſe of the word, *to cancel*, is to deface an obligation, by paſſing the pen from top to bottom, or acroſs it; which makes a kind of chequer lattice, called by the Latins *cancelli*.

CANCELLING *of deeds*, *letters patent*, and *wills*. See theſe articles.

CANCELLUS, in *Entomology*, a Fabrician ſpecies of GAMMARUS (*Cancer*, Linn.) found in the rivers of Siberia. It is ſpecifically diſtinguiſhed by having four hand-claws which are deſtitute of fangs, and ſixteen feet. Pallas deſcribes the ſame inſect under the name of *cancellus*, but as an oniſcus. This crab is of a ſmall ſize, being very little larger than *gammarus locuſta*, and has the firſt pair of antennæ incurvated.

CANCELLUS *araneoides*, Petiver's name of *Phalangium reniforme*. Linn.

CANCER, *the Crab*, in *Aſtronomy*, one of the twelve ſigns of the zodiac, and one of the 48 old conſtellations; ordinarily repreſented on the globe in form of a crab, and in aſtronomical books denoted by a figure much reſembling that of the number ſixty-nine; thus ♋. The reaſon generally aſſigned for its name, as well as figure, is a ſuppoſed reſemblance which the ſun's motion in this ſign bears to that of the crab-fiſh. As the latter walks backwards, ſo the former in this part of his courſe begins to go backwards, or recede from us; though the diſpoſition of ſtars in this ſign is by others ſuppoſed to have given the firſt hint to the repreſentation of a crab. The Greeks pretend that when Hercules was contending with the Lernæan hydra, a crab which crawled upon the marſh ſeized his foot. The hero, however, cruſhed the reptile to pieces under his heel; but Juno, in gratitude for the offered ſervice, though inconſiderable, advanced the creature to the heavens. The ſtars in the ſign Cancer, Ptolemy makes 13; Tycho 15; Bayer and Hevelius 29; Mr. Flamſteed no leſs than 83. For an eſtimate of the comparative brightneſs of ſeveral ſtars in the conſtellation Cancer by Dr. Herſchel, ſee Phil. Tranſ. vol. lxxxvii. p. 311, &c.

CANCER, *tropic of*, a leſſer circle of the ſphere parallel to the equator; and paſſing through the beginning of the ſign cancer. See TROPICS.

CANCER, in the *Military Art*. See ARIES.

CANCER, in *Surgery*, is a diſeaſe reſpecting which the moſt enlightened and experienced practitioners, for more than two thouſand years, have confeſſed their extreme ignorance; while ſome of the illiterate and unſkilful part of mankind have never ceaſed to boaſt of their ſpecific remedies, and ſtill continue to impoſe on the unfortunate victims of this deſtructive malady.

It cannot be at all doubted that numerous caſes on record, denominated *cancer*, and perhaps all thoſe in which cures of this diſeaſe are ſaid to have been performed without deſtroying or removing the part affected, were complaints of a very different nature, and ſometimes of an entirely oppoſite character. A large proportion of the remedies employed by empirics and nurſes for the cure of cancer includes thoſe means which, after long and mature trial, have been rejected as inefficacious by regular ſurgeons; and, it is well known, that the more innocent (becauſe leſs active) ointments, and other compoſitions, now publickly advertiſed by cancer-curers, are ſuch as no perſon could have propoſed who had the ſlighteſt acquaintance with the real forms of this diſeaſe.

The ambiguous and undeciſive ſtate of our knowledge in the diagnoſtic ſigns of cancer, has been a moſt fertile ſource of error and deception; and, "while we remain unfurniſhed with authentic ſtandards," or eſtabliſhed data, "by which all obſervations may be examined, it ought not to excite ſurpriſe, if the ſame name be aſſigned to two complaints, the hiſtories of which are repugnant to each other; or, if oppoſite modes of treatment be directed for diſeaſes that bear a common appellation." See Mr. Pearſon's "Obſervations on Cancer," pref. p. v.

A great deal of commendable pains has been lately taken, by the promoters of two public inſtitutions in London, to inveſtigate the nature and treatment of carcinomatous diſorders; but, from the firſt reſults of their labours, we ſcarcely can ſay that any approaches have yet been made towards the attainment of ſo deſirable an object. One of theſe gentlemen has ſhewn, with much clearneſs and acumen, that our beſt definitions of ſcirrhus and cancer have been very inaccurate and erroneous; whereas another ſurgeon, of conſiderable reputation and experience, affirms that "there can be no difference of opinion reſpecting the nature of the complaint;" for, ſays he, "the truly ſcirrhous tumour, which is known to be capable of forming the cancerous poiſon, when allowed to increaſe in ſize, has been ſo often deſcribed, that every ſurgeon muſt be enabled from thoſe accounts to pronounce the tumour, when he meets with it, to be of that kind. See Mr. Home's Obſervations on Cancer, 8vo. Lond. 1805, p. 156. This author likewiſe thinks he has proved decidedly, "that cancer is not a diſeaſe which immediately takes place in a healthy part of the body, but one for the production of which it is neceſſary the part ſhould have undergone ſome previous change, connected with diſeaſe;" whereas Mr. Pearſon has adopted the contrary opinion, viz. "that a cancer is always an original diſeaſe, and never appears as the ſequel of any morbid affection whatever."

The truth is, we are ſtill in the dark concerning the proximate cauſe of ſcirrhus and cancer, or the nature of that peculiarity of conſtitution in different perſons and ſexes, which prediſpoſes them to this malignant derangement of animal ſtructure. We do not even know preciſely in what the cancerous ſtate of an organ conſiſts; and it is yet debated in the medical world whether or no the diſeaſe be local;—although, in our own judgment, the affirmative propoſition is always true in the early ſtages of a cancer.

If we may credit the accounts publiſhed by various authors, it appears that there is ſcarcely any part of the body which is wholly exempted from the attacks of a cancerous affection: but it has been aſcertained by reiterated obſervation, that glandular parts are much more liable to this diſeaſe than any other; and it is to a gland only that we are accuſtomed to apply the term SCIRRHUS, which denotes a morbid condition invariably tending to the ſtate of a perfect or genuine cancer.

The name of ſcirrhus has too vaguely and unguardedly been applied to indurated tumours of the non-ſecreting or abſorbent glands, and hence has ariſen the epithet of "venereal or ſcrofulous ſcirrhi;" ſo that patients labouring under ſuch indurations have often been alarmed without any neceſſity. Indeed, Mr. Pearſon ſays, he "never met with an unequivocal proof of a primary ſcirrhus in an abſorbent gland." We entirely agree with this judicious writer, that ſuch an occurrence is exceedingly rare; but we have ſeen at leaſt one caſe of idiopathic ſcirrhus in the abſorbent glands of the groin, which proved fatal.

A true ſcirrhus, before it degenerates into a cancerous ſore, is hard and unequal on its ſurface, ſlightly ſenſible to the touch, not tending to ſuppuration, and enlarges very ſlowly in its commencement; but at length, aſſuming a more active form, it is ſurrounded with ſuperficial varicoſe veins, when it becomes rather painful, and changes the texture of the adjacent cellular membrane or cuticular covering, to which it frequently adheres: the ſkin will, in this advanced period, ſometimes be diſcoloured, and puckered or retracted, eſpecially in the female breaſt; perhaps attended with a degree of ſoftneſs or fluctuation in ſome part of the tumour, with ſhooting pains in its neighbourhood; and at laſt breaking into a malignant ſore, with fungous fleſh, and retroverted edges, where it is named an open cancer.

Eroding, ſordid, and rebellious ulcers will ariſe ſpontaneouſly in various parts of the body, without being preceded by a ſcirrous tumour; and, as many of thoſe reſemble the cancerated ſore, in their general appearance and fatal termination, they have been indiſcriminately ranked among cancers, for want of a better claſſification. See the articles ULCER, LEPROSY, and ELEPHANTIASIS.

The ſcirrhous tumour, above deſcribed, which has a conſtant tendency to degenerate into a confirmed cancer, (though not always equally rapid in its progreſs) will ſeldom or never yield to diſcutient applications; and ſhould therefore be extirpated without delay, if the circumſtances of the patient do not otherwiſe prohibit this operation. The ſcirrhus, on its removal, will exhibit a ſomewhat different appearance in its ſtructure, according to the progreſs it has previouſly made towards maturity. In its early ſtage, the centre is more denſe and ſemi-cartilaginous than the circumference, the whole being interſected by irregular bands of a ligamentous texture, blended with glandular ſubſtance; but as it advances, this central point is leſs obſervable, although the interſecting filaments ſtill exiſt, and an irregular ſpongoid cavity is formed within the tumour, filled with a bloody fluid. Sometimes the maſs is compoſed of ſeveral diſtinct portions, enveloped by the ligamentous bands diſpoſed in concentric circles; and in other caſes there are cyſts of various magnitude, in different parts of the tumour, which Dr. Adams believes to be real hydatids, poſſeſſed of vitality.

Means have been adopted by ſeveral practitioners at different times, to analyſe ſcirrhous or cancerous maſſes; but without affording, hitherto, any ſatisfactory reſults. Indeed, the teſts to which they have ſubmitted theſe morbid ſubſtances muſt have entirely decompoſed them and altered their nature; ſo that, probably, we ſhall not obtain much uſeful information by having recourſe to chemical agents for this purpoſe.

The chief deſideratum in ſurgical practice, is to diſcriminate between ſcrofulous indurations and ſcirrhous tumours in the living body; for it is a queſtion, on which the well being of patients muſt often depend, to determine the preciſe nature of a diſeaſe, before we proceed to active meaſures. Notwithſtanding the apparent confidence with which Mr. Home, in a paſſage we have quoted, ventures to pronounce reſpecting the facility of diſtinguiſhing and aſcertaining a ſcirrhous affection, he, in another part of this book (p. 167.) acknowledges himſelf to have frequently been miſtaken in his diagnoſis; and theſe are his words:

"So much does the ſame diſeaſe differ in its appearances, in different patients, from the endleſs peculiarities of their conſtitutions, by which every part of their body muſt be more or leſs influenced, that it is not poſſible in practice to diſtinguiſh, in all caſes, between cancerous and ſcrofulous tumours, after they have advanced to a certain ſize; and I am ready to confeſs that, in *many inſtances*, I have miſtaken the one for the other, and have removed, by operation, tumours which, at the time, had the appearance of being cancerous; and upon examination, after their removal, found them of a ſcrofulous nature. On the other hand, I have neglected to remove tumours, from the circumſtances making it probable that they were ſcrofulous; which afterwards became cancerous, and deſtroyed the patient."

In all ſuch doubtful caſes, it is the ſafeſt rule to adviſe the removal of the tumour, if it be ſituated fairly for the operation; as it is a much leſs ſerious inconvenience to get rid of a diſeaſed ſcrofulous gland, than to retain a ſcirrhous tumour, which probably might coſt the patient his life, in the event of its contaminating the adjacent parts by its malignity. There is reaſon to ſuſpect that many ſurgeons, who boaſt of their extraordinary ſucceſs in extirpating cancers, have ſometimes diſſected out tumours which might very innocently have remained: for the ſurpriſing diſparity we find, in the reſults of the practice of different ſurgeons, is not capable of being reconciled by any other ſuppoſition.

Thus Mr. Nooth aſſerts "that in 102 ſchirrous caſes, in the early ſtage of the diſeaſe, where he performed the operation, all remained free from any return of the complaint;" whereas Dr. Monro ſen. ſays, "of ſixty cancers, which he had ſeen extirpated only *four* remained free of the diſeaſe for two years," and theſe became cancerated afterwards!

This report of the late Dr. Alexander Monro (in Edin. Med. Eſſ. Vol. 5.) is ſo very diſcouraging, that it will not be improper to ſuppoſe the failures in thoſe caſes aroſe from ſome peculiarly untoward circumſtances; and yet we have another account, by Mr. J. Hill, "of no leſs than 88 genuine cancers, all ulcerated except four," being extirpated by himſelf, and "all the patients but two recovered of the operation." Mr. Hill ſays, "of the firſt 45 caſes, only one proved unſucceſsful: in three more the cancer broke out in different places: and a fifth was threatened with ſome tumours at a diſtance from the original cancer; theſe tumours did not appear till three years after the operation; but the woman was carried off by a fever before they had made any progreſs. All the reſt of the 45 continued ſound ſo long as they lived, or are ſo to this day; one of them ſurvived the operation above 30 years; and 15 are ſtill alive, though the laſt of them was cured in March 1761.

"Of the next 33, one lived only four months; and, in five more, the cancers broke out afreſh after having been once healed.

"The reaſon why, out of 45 caſes, only four or five proved unſucceſsful, and ſix out of 33, was owing to the following circumſtance: the extraordinary ſucceſs I met with made cancerous patients flock to me from all corners of the country, ſeveral of whom, after delaying till there was little probability of a cure by extirpation or any other means, forced me to perform the operation, contrary both to my judgment and inclination.

"Upon a ſurvey in April 1764, the numbers ſtood thus:

| | | |
|---|---|---|
| "Total cured - - - | | 63 |
| "Of whom, when cured, there were aged between - - - | 70 and 80, | 15 |
| | 60 and 70, | 17 |
| | 50 and 60, | 18 |
| "Below 50, or ages unknown | | 13 |
| | | 63 |

| | | |
|---|---|---|
| "Of the above 63, there were alive in April 1764, | | |
| "Aged between | 80 and 90, | 4 |
| | 70 and 80, | 8 |
| | 60 and 70, | 12 |
| "Below 60, or ages unknown - - | | 15 |
| | In all | 39 |

"In 28 of the above number, the operation had been performed more than two years before.

"In 11, the operation had been done in the courſe of the two laſt years.

"So that, upon the whole, after a courſe of 30 years practice, 39 of 63 patients were alive and ſound.

"From the above ſurvey, it appears, that the different patients lived as long after the extirpation of the cancers as, according to the bills of mortality, they would have done, had they never had any cancers, or undergone any operation.

"The remaining 25, which compleat the 88, were cured ſince the year 1764, 22 of whom have been at leaſt two years cured: one or two of theſe patients were 70 years of age, one 90.

"Mrs. Mundal was 90 when ſhe got a cancer cut off her cheek, 28th June 1768; another appeared on her under-lip in 1770, and was extirpated on the 5th of April that year. After both which ſhe recovered; but a tumour appeared below the *maxilla*, which carried her off in November 1771, above three years after the firſt exciſion; that is, when ſhe was 93 years old.

"The ſum therefore at preſent, July 1770, ſtands thus:

| | |
|---|---|
| "Of 88 cancers extirpated, at leaſt two years ago, | |
| "Not cured - - - | 2 |
| "Broke out afreſh - - | 9 |
| "Threatened with a relapſe - - | 1 |
| | 12 |

"Which is leſs than a ſeventh part of the whole number.

"At this time there are about 40 patients alive and ſound, whoſe cancers had been extirpated above two years ago.

"Of five cancered breaſts, only one was ulcerated, which, with one of the occult kind, did not heal; a third relapſed, probably owing to the whole not being fully cut away; the other two are ſtill firm and ſound in 1772, though one of them was cut October 25th 1761, and the other April 26th 1766." See Mr. Hill's Caſes in Surgery, 12mo. Edin. 1772.

This author's experience, we perceive, was by no means ſo diſcouraging as that of Dr. Monro, nor was it ſo completely unfailing as that of Mr. Nooth: but it ſhould be remarked, that Mr. Hill's caſes were much worſe, and more advanced than thoſe of Mr. Nooth, while the circumſtances are not known which occaſioned the ill ſucceſs alluded to by Dr. Monro. Upon the whole then, we think the numerous patients who are afflicted with external cancers need not ſit down in deſpair; as if it were uſeleſs to undergo the operation, when performed in due time, and by a ſkilful ſurgeon. The reſult of our own practice has not been ſo favourable as that of Mr. Nooth, but has proved at leaſt as ſucceſsful as Mr. Hill's; and we have no reaſon to doubt that our contemporaries have been equally happy in their experience after the operation.

To avoid the diſtreſs and pain attendant on ſuch a ſurgical operation as that of cutting out the part affected, a great variety of means, both external and internal, have been propoſed for the cure of cancer: theſe may be ranked under the ſeveral heads of 1. Diſcutients.—2. Corroſives.—3.

3. Narcotics. We could ſubjoin a long liſt of thoſe remedies from the vegetable, animal, and mineral kingdoms; but ſince no ſurgeon of reputation will truſt to any of them, after the varied trials which have been ſo often made, both in this country and upon the continent, we ſhall not extend the preſent article by reciting their names and ſuppoſed qualities. A few words may, however, be added reſpecting the moſt eligible means of palliating ſymptoms either before the cancer is confirmed, or when it has gone on to a ſtate of ulceration, and cannot be extirpated.

Many hard ſwellings in the breaſt, eſpecially thoſe of a ſcrofulous kind, and ſuch as appear after child-bearing, have been miſtaken for cancerous tumours; but they may generally be diſperſed by the early and repeated application of leeches, bathing with camphorated ſpirits, ſoap liniment, hemlock poultices, ſaturnine lotions, or gentle rubbing with mercurial ointment. It has been juſtly obſerved by Mr. Home, "that the ſucceſs met with in ſome of theſe caſes is often productive of material miſchief, by inducing the practitioner to be too ſanguine, and to go on with the uſe of the ſame means in other caſes, encouraged by his former ſucceſs, till the diſeaſe has arrived at the ſtate of a true cancer; and therefore has advanced beyond that ſtage in which it might have been removed by the operation of extirpating the tumour."

It is of great importance, on the one hand, not to alarm our patients prematurely, by giving too haſty and unfavourable an opinion; but, on the other hand, practitioners would do well to weigh all the circumſtances which may enable them to decide on the nature of ſuch tumours, and if they are confident of their being carcinomatous, to loſe no time in adviſing the only ſtep which can be taken for the ſecurity of the unfortunate ſufferer.

The following are Mr. Hill's rules of determining whether an external ſwelling be of a cancerous nature or not; viz.

" 1. When ſchirrous tumors are conſiderably advanced, they are ſurrounded with large varicoſe veins, reſembling crabs claws, from which reſemblance they have got the name of cancers. The abſence of theſe, therefore, is a favourable circumſtance, but not to be abſolutely depended on.

" 2. The ſkin of a cancer, when near burſting, is of a reddiſh blue, or a blue livid colour, adheres to the under part of the indurated gland, (from which it was originally detached), and is puckered up into ugly folds, as if ſcorched.

" 3. On the other hand, the ſtruma, or boil, when inflamed, is always accompanied with a fever, which keeps pace with the degree of inflammation. But a cancer is never attended with a high inflammatory fever. It is true, the exceſſive pain of a cancer ſometimes quickens the pulſe, but at the ſame time ſinks it.

" 4. The ſkin of the inflamed ſtruma, or phlegmon, inſtead of being wrinkled or plaited, is ſmooth, red, and ſtretched, ſo as ſometimes to have a glazed appearance; and, when near burſting, the matter is always found fluctuating below, which ſeldom happens in cancers. On the contrary, cancers are generally accompanied with a corroding humour, which abrades the cuticle, till the outer parts are conſumed; but no matter is perceived within; whereas, in the ſtruma, &c. the ſcarf-ſkin is the laſt part that gives way, unleſs it be ſcalded or fretted by too hot poultices.

" 5. The cold ſcrophulous tumor is in ſtill leſs danger of being miſtaken than the inflammatory kind. For the pain and hardneſs are not ſo conſpicuous as in the inflammatory tumor; and the matter accumulates for a long time before it burſts. In either kind, if good pus appear, there is no occaſion for being afraid of a cancer: and, although the pus ſhould not be of the moſt laudable kind, but of a whitiſh ſanious aſpect, ſtill it is never ſo acrid as that which proceeds from a cancer. Nay, even a red, bloody, or ſanious matter, is not of itſelf a characteriſtic ſymptom of a cancer. Excepting the caſe mentioned above, I have never ſeen any cancer that contained matter; but I have ſeen numbers of other ulcers, in bad habits of body, full of bloody ichor."

The boaſting cancer-curers of our time have not ſufficient knowledge to diſcriminate between the different kinds of tumours they meet with, and perhaps too little honeſty to confeſs that the caſes in which they have ultimately had ſome ſucceſs were really not cancerous; for ſuch an acknowledgement would annihilate their traffic, and deſtroy their ill gotten reputation. But our own opportunities have enabled us to affirm, that this mercenary claſs of practitioners ſubſiſt chiefly by impoſing on the credulous and inexperienced part of mankind, eſpecially the weaker ſex, who are terrified with curable diſorders, falſely named cancers.

Suppoſing it to be aſcertained that a cancer exiſts, and it has proceeded to a ſtate of ulceration, not admitting of a ſurgical operation, the patient ſhould avoid uſing any means of relief which irritate and give pain; unleſs it be propoſed to deſtroy the whole by a cauſtic, which indeed is a far more tedious, uncertain, and tormenting plan of treatment than by cutting out the part.

The topical applications to an open cancer, which have been found moſt uſeful to alleviate pain, cleanſe the ſore, or to correct the fetid ſmell ariſing from it, are as follow:—1. Freſh bruiſed hemlock leaves.—2. Scraped young carrots.—3. The fermenting poultice.—4. Finely levigated chalk.—5. Powdered charcoal.—6. Carbonic acid gas.—7. A watery ſolution of opium.—8. Liquid tar, or tar-water. The internal remedies which have been moſt beneficial are, 1. Very ſmall and long continued doſes of arſenic.—2. Liberal doſes of cicuta.—3. The free uſe of opium.—4. Belladonna.—5. Solanum.—6. Martial flowers.—7. Corroſive ſublimate.—8. The juice of clivers or gooſe-graſs. But neither the external nor internal remedies, however apparently uſeful for a time, can be in the leaſt depended on for the cure of a genuine confirmed cancer.

The removal of ſcirrhous tumours and cancerous excreſcences may be effected in various external parts of the body; but no ſurgeon perhaps could now be found to undertake the exciſion of any internal organ, for example the uterus. Attempts have been often made by ignorant and bold empirics to deſtroy a cancerous ulcer of the womb by corroſive injections; but the practice is as cruel as it is abſurd, and we have ſeen the moſt dreadful conſequences from ſuch attempts, without affording the ſmalleſt relief to the unhappy patient. Several examples are recorded of the uterus having been exſcinded, and ſome of theſe women have ſurvived; but no caſe, that we know of, is related of ſuch an operation being performed for the purpoſe of extirpating a cancer, although we are aware that it has been lately propoſed by a ſpeculative writer of Germany. See Med. and Phyſ. Journ. vol. xi. p. 34.

The circumſtances which indicate the propriety of an operation are theſe:—1. When the cancer is ſo ſituated as not to expoſe any large blood-veſſels or nerves to be cut during the operation.—2. When the whole of the morbid parts can certainly be removed.—3. When the diſeaſe has ariſen from ſome accident, and not ſpontaneouſly.—4. When the patient is otherwiſe healthy.—5. When the cancer has not ſhewn evident ſymptoms of conſiderable malignancy during its progreſs, and does not ſeem to have involved the adjacent glands or abſorbent veſſels. The two firſt of theſe requiſites are not to be diſpenſed with; for unleſs we can diſſect out all the morbid parts, without incurring the danger of dividing important nerves or arteries, this operation muſt never be attempted.

The mode of operating will vary in different caſes and ſituations. Some excellent directions are given on this ſubject by Meſſrs. Fearon, Home, Pearſon, Bernſtein, Richter, Le Dran, Sabatier, and Calliſen; which young ſurgeons ſhould conſult, in particular emergencies: the only general rules we can here lay down are,

1. To make the external wound nearly in the direction of the ſubjacent muſcular fibres, and to make it large enough for the removal of all the morbid parts.
2. To ſave all the ſkin which is not diſeaſed, unleſs there ſhould be too much to heal up neatly.
3. To ſecure every bleeding veſſel, by a ligature, which might hazard a ſubſequent hæmorrhage.
4. To maintain the lips of the wound in cloſe contact, without interpoſing any dreſſing or extraneous ſubſtance between them.
5. To preſerve the parts in an eaſy and ſteady poſition for ſome days, before they are looked at or opened.
6. To uſe no other than mild and cooling applications during the cure.

The only point of importance on which we have as yet offered no obſervations, but which will nevertheleſs be deemed highly deſerving of general attention, is the comparative advantages and diſadvantages attending the modes uſually employed for the extirpation of cancers.

This is a ſubject, reſpecting which, unprofeſſional readers, eſpecially thoſe who ſuffer from the complaint, may naturally deſire to make up their minds; and, on that account, we ſhall not heſitate to lay before them the judicious remarks of a late author, who has treated this queſtion very amply. See Home's Obſerv. pp. 178—189.

" There are two modes by which a cancer may be extirpated; one is, taking out all the parts that are diſeaſed, by a cutting inſtrument; the other, making uſe of ſuch applications as will render them dead, and thereby occaſion their being thrown off.

" The advantages attending the operation by the knife are ſuch as to give it a decided preference in all cancerous diſeaſes. It is the only mode which is capable, in the more advanced ſtate of the diſeaſe, of removing the contaminated parts to a great extent; and, in doing it, the ſurgeon is enabled to take away with preciſion every part he thinks liable to have been affected. When the operation is over, he can examine the diſeaſed part that has been extirpated, and ſee whether it is every where ſurrounded by healthy parts; and, if it is not, by referring it to its natural ſituation can remove any part which may give him the leaſt cauſe to ſuppoſe that it is contaminated. The ſkin, after ſuch an operation, is in a looſe ſtate, and admits of its edges being brought together, ſo that the wound may always be much diminiſhed in ſize; and, in very many inſtances, the cut edges may be brought together like thoſe of a ſimple inciſion.

" The operation is only of a few minutes continuance, and the moment it is over, the parts are in a ſtate to commence the proceſs which is neceſſary for their recovery; and in the courſe of two or three weeks they are entirely healed, even where the diſeaſe has not been completely removed.

" The modes of deadening the diſeaſed part, which have at different times been employed, are three; and as theſe have ſometimes been preferred to the operation by the knife, and ſome of them are ſtill in uſe, it becomes neceſſary to explain in what way they acquired their reputation, and to ſhew the diſadvantages which attend their operation.

" In the earlier times, when the knowledge of cancer was ſtill more imperfect than it is at preſent, an idea was entertained of its growth being ſimilar to that of a vegetable; and it was therefore thought that unleſs it was taken out by the roots, the diſeaſe was not completely removed. It was then found that very active cauſtics were capable of deadening the whole tumour, which is always more or leſs of an irregular form; and when the diſeaſed part was thus brought away, the projecting portions were conſidered as the roots of the cancer; and the proof of its being completely eradicated was, that the ſore readily admitted of being healed. Any recurrence of the diſeaſe from the contaminated parts, which had not been deſtroyed, was ſuppoſed to ariſe from the conſtitution having been in a diſeaſed ſtate, and not from any failure of the action of the cauſtic: and in this way the original idea of its being a conſtitutional diſeaſe was moſt probably formed.

" The fact is, that diſeaſed parts have leſs powers of ſupporting themſelves than healthy ones, and therefore are more readily deſtroyed; ſo that a powerful cauſtic acts to twice the extent, in a diſeaſed part, to what it does in a natural one; and an indolent tumour can have every part of it deadened by means that would only produce a violent inflammation upon the common ſkin. It was therefore by no means an unfair concluſion, till it was contradicted by experience, that ſuch applications as were capable of deadening every part that was in a diſeaſed ſtate without acting upon the healthy ſurrounding parts, were to be preferred to the operation by the knife; and it is within my own remembrance, that ſuch an opinion was general in London. Since that time, two things have been aſcertained, which prove, that when the tumour has become cancerous, ſuch cauſtic applications are incapable of removing the diſeaſe entirely; the one, that when the poiſon is once formed, the contamination precedes and extends beyond the diſeaſed alteration of ſtructure; the other, that every thing which irritates the diſeaſed part increaſes its action, and its power of contamination: and in fact, all regular practitioners have laid aſide the arſenical applications to cancerous tumours in the breaſt, in conſequence of finding that the diſeaſe was rarely removed by them.

" They ſtill retain a certain degree of reputation, and are uſed by ſeveral empyrics in London; and cures performed in this way are well authenticated; that is, they ſucceed when applied to tumours which are yet in an indolent ſtate, if they are ſufficiently powerful to deſtroy the whole tumour; and as there is no poſſibility of aſcertaining what the ſtructure of the tumour was, which has been thus deſtroyed, it is ſtated by the practitioner to have been an inveterate cancer, which is attempted to be proved by ſhewing its roots, or the irregularities upon its external ſurface. But the cauſtic, when too weak for the deſtruction of the diſeaſed part, irritates, and makes it ſooner become cancerous. When applied to a cancerous tumour, although ſtrong enough to deaden the whole, it irritates the ſurrounding parts that have been previouſly contaminated, and makes them ſooner aſſume the characters of the diſeaſe. This not only happens when cauſtic applications are uſed, but when mortification takes place from any other cauſe, as in the caſe ſtated in a former part of this work.

" This fact of the contaminating power of morbid poiſons being increaſed by any thing that irritates the diſeaſed parts, is not peculiar to cancer. It happens alſo in the venereal diſeaſe, of which too many inſtances have come under my own obſervation.

" It has been, for ſome years, a favourite practice to attempt the cure of chancres by touching them with cauſtic, while yet of a ſmall ſize, and repeating the application till a ſound ſurface is expoſed, after the ſlough has been thrown off, and then to allow it to heal. The effect of this practice is exactly ſimilar to what has been ſtated. The chancre is cured, but the poiſon is abſorbed, and the conſtitution contaminated by the diſeaſe. But if the chancre be ſo ſmall, when the cauſtic is firſt applied, that the whole ulcer and ſome of the ſurrounding parts are deadened completely by one application, the patient will then be perfectly cured of the diſeaſe; as there was not time for abſorption before the application was made, and its effects were ſuch as to preclude its taking place afterwards. If, on the contrary, the firſt application only deſtroys a part of the diſeaſe, it irritates the abſorbents, and gives them a diſpoſition to take up the poiſon at an earlier ſtage than is uſual. From an experience of this being the caſe, I have for many years entirely left off the practice of uſing ſuch modes of treatment, in the early ſtages of chancres.

"The cauſtic applications which have been employed for the deſtruction of cancerous tumours are the following: arſenic, corroſive ſublimate, and the actual cautery. As theſe means are alſo uſed for the purpoſe of removing other tumours, whoſe ſtructure prevents the knife from being employed, I have had frequent opportunities of making obſervations on their comparative effects. Indeed the ſtatement contained in the ſecond caſe which has been mentioned in this volume, explains their different effects upon the ſame perſon, ſo as to afford us the moſt ſatisfactory information reſpecting them.

"The only preparation of arſenic which I have uſed, is equal parts of the white arſenic and ſulphur; theſe proportions were firſt recommended to me by Mr. Cline. This acts as a powerful cauſtic, and appears capable of deſtroying any tumour which has not acquired the diſpoſition to throw out a fungus. The ſloughs formed by each application will be very much in proportion to the quantity of the powder applied. By this means I have removed a large tumour in the cheek, which appeared to be taking on the previous ſtate to becoming a cancer. I have alſo deſtroyed a large tumour in the foot. In the laſt caſe it certainly affected the conſtitution, in a manner very ſimilar to what has been already deſcribed. In the other, no ſuch effect was produced; ſo that it would appear that the arſenic is in ſome caſes abſorbed more readily than in others.
